The "out-door assistant" is a gentleman who does not live with the principal, but who usually resides near the house of his employer. The term "out-door" is not intended to convey the idea that his duties are wholly "extern," but simply indicates his mode of life. The out-door assistant sometimes lives in lodgings at his own expense, sometimes in rooms furnished and provided by the surgeon for whom he acts, sometimes the room may be in the adjoining house where the "surgery" is, sometimes in a residence at some distance. In the latter case there may be a "branch practice" to be "conducted." In all cases where the assistant resides elsewhere than with the surgeon, proportionately larger salaries are given to compensate for extra expenses. These situations are supposed to afford greater personal freedom, but more completely exclude the holder from pleasant society. Where a branch practice is carried on, a separate house and surgery are provided at the expense of the principal, who in such cases may visit the locality only once or twice a week. Candidates for these appointments are expected to have a double qualification, and to be able to take sole charge of the cases entrusted to them. No one who is not thoroughly competent in midwifery should entertain the idea of taking a branch practice.

Assistantships, *with time to attend lectures, &c.*, are not unfrequently sought after. Formerly such appointments were not uncommon, but experience has shown that they work so badly both for surgeons and pupils that they may be said to be almost extinct.

#### THE LEGAL RELATIONS OF THE PRINCIPAL AND ASSISTANT.

The engagement of an assistant may be made by word of mouth or by writing. The usual written contract between the parties (where apprenticeship is not intended) is an agreement of the ordinary character; but in the case of unqualified assistants the engagement is verbal, or made by correspondence between the parties.

Arrangements are sometimes made under which assistants are paid a certain percentage upon the fees received by the principal for work done by his subordinate; and often in cases of branch practices, a proportion of the gross profits is awarded to the assistant.

#### TERM OF ENGAGEMENT AND DISMISSAL.

In cases where there is no written contract with a permanent assistant engaged nominally for the year, and the salary is paid *weekly*, it is the custom in the medical profession to give and require a *month's* notice. But in temporary engagements, such as those made for *locum tenens*, the invariable custom is to pay by the week, the contract being terminable at any time by the wish of the principal. In such cases the gentleman employed is always expected to give reasonable time—say seven days—to provide a successor, if circumstances induce him to wish to resign the appointment.

In-door assistants, whether qualified or not, can be dismissed by a month's notice at any time, or by the payment of a month's salary by the principal; the assistant, however, who leaves without giving a month's notice is liable to summary punishment by a magistrate, nor would the tender of a month's salary in lieu of notice relieve him from this liability to punishment; moreover, he would also forfeit all claim to any salary due to him from his principal for any services rendered previous to his leaving.

The services of gentlemen engaged for special services and temporary duties may be terminated without notice unless

there is a special understanding that the engagement is for one day, a week, or four weeks.

#### LEGAL OBLIGATIONS ON THE ASSISTANT.

Every assistant is bound by law to obey all the lawful and reasonable orders of his employer, and to be honest and diligent in the professional duties required from him; he is required also to pay proper respect to the principal. He is bound to take care of the property entrusted to him, and, if guilty of gross negligence, will be liable to an action.

When an assistant is engaged on account of his fitness to perform certain duties (such as "to visit," dispense, and attend midwifery), and turns out to be perfectly incompetent to do any one of these things, the principal will be justified in rescinding the contract at once, and discharging the assistant, and it would be of no avail for the latter to prove his "qualifications" in the highest walks of his profession, if he were incompetent to perform those duties.

## MEDICAL EDUCATION IN ENGLAND AND SCOTLAND.

### THE CAREER OF THE MEDICAL STUDENT.

THE young gentleman who is about to enter the Medical Profession in *England* has more than one course open to him, whether he decide on fulfilling his curriculum in London or in one of the provincial schools. The latter course is generally determined by local causes with which pupil and parent are both familiar. We propose, therefore, in this place, to point out a few things that concern alike the London or provincial medical student.

#### APPRENTICESHIP.

First of all, as to apprenticeship. The only English corporation that absolutely requires an apprenticeship is the Society of Apothecaries, which is bound by Act of Parliament. The clause, however, is very liberally interpreted, and the apprentice may, during his term, fulfil part or the whole of the curriculum. *The master must possess the licence of the Company*, but he may practise any department of the Profession. There is much difference of opinion as to the value of an apprenticeship. Some profess to despise it, and regard it as a badge of trade. There are, however, many advantages in the system, if carried out in the liberal mode we have spoken of; and we feel sure neither pupil nor parent would ever regret having entered into such an agreement with a medical gentleman of position and honour. Thus, suppose a pupil to be bound apprentice to a Licentiate of the Apothecaries' Company for a period of five years, with the right to attend lectures and hospital practice during the last three years, he enjoys the following advantages: In the early part of his pupilage he not only learns practical pharmacy, and becomes acquainted with the more generally used articles of the *Materia Medica*, but may be assisted in preparing for the Preliminary Examination. Moreover, he prepares himself to take, should he ever wish to do so, the post of assistant to a general practitioner, as the experience he has thus acquired will procure him a situation in preference to prizes, gold medals, and even university distinctions. Again, this experience is of the very highest value, should he decide on settling in general practice after he is qualified. On the whole, then, this modified apprenticeship system is equal to any, and parents who know a practitioner to whom they would willingly entrust their sons, cannot do better than pay him

a fair premium. Those residing near will occasionally be able to arrange for an out-door apprenticeship.

#### PUPILSHIP.

Supposing, on the other hand, that the plan of apprenticeship be rejected, a young man may still become the pupil of some one in practice. This is often done by those who aim at the higher branches of practice. A physician or surgeon who will give some time to the superintendence and direction of a pupil's study certainly offers him great advantages, and those who can afford thus to act will not regret the expense of providing their sons with such a guide.

#### HOSPITAL STUDY.

Lastly, a pupil may enter at any of the London hospitals without any such preparation. He has only, *provided he has passed a preliminary examination*, to pay the first year's fees, and he is admitted at once to all the dignity of a medical student. A preliminary examination recognised by the General Medical Council *must* be passed before entering a hospital. He should decide on the diplomas he requires, and guide his studies accordingly. Most of the schools now have a composition fee, entitling to all lectures and practice required for the ordinary qualifications in medicine and surgery. They also mostly have another sum, very little higher, entitling the student to perpetual attendance on all lectures and hospital practice. It is better to take out the perpetual ticket, as all contingencies are thereby provided for. The fees are mostly payable in two or three instalments, at the commencement of each Winter Session. The Dean will always forward details, as well as any special information of which a student may find himself in need. The first instalment varies from forty to fifty guineas; the second is a like sum; the third usually only makes the whole sum paid a hundred guineas or a little over. There is a tendency to slightly increase the expenses in consequence of the great improvements in the schools, and the additional requirements of the Examining Boards, and no doubt the fees in London will gradually rise.

#### RESIDENCE.

The student who comes from the country to enter in London not unfrequently requires lodgings. Those who can live with relatives and friends are, of course, best suited; but not a few find themselves very comfortable in furnished apartments, which are to be had in respectable streets near all the hospitals. Two brothers or two friends can, of course, do this a little less expensively than one. The price varies with the season a little, and some can afford more than others, and therefore can all ways have a selection of better rooms.

It should be mentioned that one or two of the medical schools have collegiate institutions in connection with them, where rooms may be had instead of the more usual plan of taking lodgings. At many schools some of the lecturers receive pupils, and all of them will at any time afford special information to those who may inquire of them.

Residence settled, student life begins by hearing the Introductory Lecture, at the conclusion of which the fees may be paid, unless they have already been handed over.

#### PRIZES.

As to contending for prizes, there are differences of opinion. Diligent attendance on the classes and in the wards will enable the student to store his mind with know-

ledge fitting him for his profession, and this should be his first aim. Gold and silver medals are honourable distinctions, but only secondary ones. We never competed for them, nor encouraged others; and some of the most eminent men hold the same views. Others, however, differ from us, and the pupil may judge for himself. Competition for appointments to dresserships and other offices, where much practice is seen, stands on a different footing. No prize can equal such posts; and the possibility of getting them should influence largely the choice of a school. In some schools they must be paid for. In others, the diligent gain them without extra expense. The student, having selected his hospital and school, has chosen his teachers. We have only to remind him that however able they may be, the result depends on his own application. Let him supplement their efforts by giving all his energy to the pursuit of knowledge, and there is not one of our schools of medicine in which he will not acquire such a knowledge of his profession, that when the time comes he will pass his examination with ease, and, what is more important still, will then be able to practise in our noble profession with benefit to the sick to whom he may minister.

#### CURRICULA AND QUALIFICATIONS.

The information most important to students may be divided into two parts—I. The regulations with which they must comply before they can present themselves for examination to any of the Licensing Bodies; II. The means that exist to enable them to do so. In the first division are to be placed the regulations of the Corporations; in the second, some account of the many Schools of Medicine and Hospitals where professional education can be pursued. A natural supplement to this information is a brief sketch of the career open to young men after they have obtained their diplomas, especially in the Public Services.

According to this plan, we proceed to consider, first of all, the regulations of the Qualifying Bodies. These may also be divided into two classes—1. The Universities; 2. The Corporations.

I.—We would here urge upon every student who may enter any University the great advantages they would derive from a course of study in the Faculty of Arts, and we strongly advise every one who has the time to take a Degree in Arts before commencing his medical curriculum. A Degree in Arts stamps a man for life; and as some examination must be passed before the commencement of professional study, it would always be best to take such a degree. A University Degree in Arts is recognised universally as the preliminary examination, and possesses its own value, besides exempting from other tests.

*Oxford and Cambridge*.—The elder English Universities have of late years opened their doors much wider than heretofore, and that without losing any of the prestige they possessed. Those who propose to follow their course of education need not any longer enter at any particular College or Hall, although it will probably be long before lodger students will be very numerous. There are advantages in the College life that will not be willingly given up by those who can afford it, and, for a purely medical career, it would be perhaps preferable for those who would not like to enter a College to graduate at the London University.

*University of London*.—The medical degrees of this University have now obtained a reputation second to none, and no student can therefore propose to himself a higher qualification. The training is rather longer than that required for the diplomas of most of the corporations.

The examinations are very stringent, and it is in after years that the student will feel the gratification of having obtained such a degree. Every student is required to go through the full course of hospital studies *after* he has passed the matriculation examination. It is, therefore, very desirable he should matriculate before entering a medical school, otherwise two years will be lost. The matriculation examination of this University is accepted as a preliminary by the Medical Council, and therefore the labour bestowed in preparation will serve the student's purpose even if he do not proceed to a degree. The medical degrees of the University are Bachelor and Doctor of Medicine, and Bachelor and Master in Surgery. Degrees of Bachelor and Doctor of Science are also now obtainable. There are at each stage of the graduate's career, examinations for honours, which afford the student the opportunity of gaining highly-prized distinctions in various branches. There are also scholarships for the most successful.

*University of Durham*—The degrees of Bachelor and Doctor of Medicine are granted by this University, as is also the degree of Master of Surgery. There is also a licence in medicine, to obtain which residence is not essential. A licentiate cannot pass to the M.B. until he has obtained the degree of B.A., or passed an equivalent examination. Only M.B.'s of twenty-one terms' standing can proceed to M.D.

There is a medical scholarship of £25 tenable for four years, and the fees, both Collegiate and University, are very moderate.

II.—From the Universities we pass to the other bodies that are empowered to give authority to practise.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON. The Fellowship of this College is only attainable by election. No one can be proposed who is not a member of four years' standing.

THE MEMBERSHIP.—A person may become a Member of this College without holding a degree in Medicine, or indeed any other diploma. This is not very often done; for the Membership gives no right to the use of the title doctor, though some Members not possessed of a degree do so style themselves. This is, however, in direct violation of the rules of the College to which a member pledges himself on admission. The curriculum extends over four years.

Graduates in Medicine of any British University are admitted to an examination for the membership. Such graduates are exempt from some parts of the examination—*e.g.*, anatomy and physiology. Even foreign graduates of accredited Universities have no difficulty in being admitted to examination.

THE LICENCE.—This diploma authorises the holder to practise his Profession as a Licentiate of the College. Unless a graduate of some University, he is forbidden to use the title of doctor, but we regret to say many do so. At first it was regarded as a medical diploma for the general practitioner, intended to supersede that of the Apothecaries' Company. The examination is conducted by specially appointed examiners, and is complete in the several departments.

Not quite three years ago we had to record the most important change that has ever occurred in reference to the qualifications of general practitioners. This licence of the London College of Physicians was then recognised by the Poor-law Board as a qualification in surgery as well as medicine. Consequently, this single diploma is sufficient to enable any one to take a Poor-law appointment. It ought, therefore, to become a single authority to practise every department of the Profession. In such case, any one contented with the diploma of L.R.C.P. Lond., would have all he needed, and the one faculty system so long desired by earnest reformers would be established.

It is to be supposed that the College will follow up its advantage, and protect all its Licentiates in the exercise of all branches of the Art of Healing.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

No Corporation has exercised so great an influence over the Profession in England as this. Without the M.R.C.S. it is not easy to obtain any English surgical appointment. In a parish appointment, its membership, though no longer essential, carries great weight. Hence, most English students intend to prepare themselves for this, which, together with a medical qualification, suffices for every purpose of the general practitioner. The College has two grades, Member and Fellow. It also gives a diploma in Midwifery, but this is mostly confined to those who are already Members.

THE FELLOWSHIP.—Members of long standing can be admitted by election. As, however, this grade is also obtainable by examination, this is the more usual mode. Consulting surgeons mostly take the Fellowship by examination, though there are many hospital surgeons in London who have contented themselves with remaining Members.

A Member of the College of eight years' standing is admitted to examination on the production of a certificate of three Fellows, that he has been engaged for eight years in the practice of surgery, and is a fit and proper person to be admitted a Fellow.

THE MEMBERSHIP.—This diploma gives no vote in the affairs of the College. It is in effect only a licence to practise, and corresponds with the licentiate of the Edinburgh and Dublin Colleges.

In future, candidates for the diploma will be examined in the practice of medicine, and also in the practical employment of splints, bandages, and other surgical appliances.

#### APOTHECARIES' SOCIETY OF LONDON.

The Licence of the Worshipful Society of Apothecaries is perhaps the most useful medical diploma for the general practitioner in England. The monopoly enjoyed by this body for many years, in this respect, is not easily to be disturbed. The laws of many institutions require their medical officers to hold this diploma, and these laws are not readily altered. Though other medical qualifications are recognised by the Poor-law Board, there is no doubt that the guardians throughout the country—and they elect the medical officers—are familiar with the diploma of the Apothecaries' Society, and it is to them more of a guarantee than other qualifications, of the value of which they are ignorant. The drawback to many a student is that, constrained by the Act of Parliament, the Society requires apprenticeship. This clause has, however, received a very liberal interpretation, and every pupil of a licentiate, who is certified to have served *after the manner* of an apprentice, is considered to have fulfilled the requirement. During this term he may also have carried on his hospital studies. Everyone, therefore, who can show this certificate, intending to settle *in England* as a general practitioner—even if he take other diplomas—would probably consult his own interest by becoming a Licentiate of the Apothecaries' Society; and as the fee is only six guineas, a very large number of young men will, we doubt not, secure this possible avenue to appointments.

Having now considered the qualifying bodies of England we pass on to the second consideration—the Schools of Medicine and the hospitals to which they are attached next demand attention, inasmuch as at one of them the Student has to go through the curriculum prescribed by the licensing bodies.

In entering a School of Medicine, application is to be made to the Dean. In London the fees range from 80 to 100 guineas for the course of study required for the ordinary diplomas. The sum, if paid at once, is less than if paid in two or three instalments. From 40 to 50 guineas at the commencement of each of the two first years is an ordinary arrangement, the remainder being paid on entering the third winter. The amount of the fees does not differ so much as to make it of importance in the selection of a school.

We now proceed to name some of the characteristics of the most important London Schools.

#### THE LONDON HOSPITAL AND COLLEGE.

The next Winter Session will commence on Monday, October 2, 1871, when the introductory lecture will be delivered by Dr. Little, formerly senior physician to the hospital and lecturer on medicine in the college. The Medical College of the London Hospital has been considerably enlarged, and lectures are given on all subjects required by the examining boards. It is a characteristic of the great East-end School of Medicine, that all its offices are conferred without extra payment. There are now offered at this school a large number of prizes and appointments of the most valuable kind, so that for practical instruction scarcely any institution equals it. The following are some of the prizes and appointments to be competed for this session:—

Two Buxton Scholarships to be awarded in October to the students who distinguish themselves most in the subjects appointed by the General Council of Medical Education and Registration as the subjects of the preliminary examinations.

A Scholarship, value £30, to the student placed first in the subjects required at the preliminary examinations.

A Scholarship of £20 to the student of less than three months' standing placed second in the above examination.

A Scholarship, value £20, in Human Anatomy for first year students, to be awarded in April, 1872.

A Scholarship, value £25, in Anatomy, Physiology, and Chemistry for first and second year students, to be awarded in April, 1872.

A Hospital Scholarship, value £20, for Clinical Medicine, to be awarded in April 1872.

A Hospital Scholarship, value £20, for Clinical Surgery, to be awarded in April, 1872.

A Hospital Scholarship, value £20, for Clinical Obstetrics, to be awarded in April, 1872.

Besides these Scholarships, there is—

The Duckworth-Nelson Prize, value £10 10s., for Practical Medicine and Surgery (biennial), and Money Prizes to the value of £60 annually for zeal in Dressing Out-patients and knowledge of Minor Surgery.

Certificates of Honour in all the classes, according to the results of the general examinations at the end of the session, and Special Certificates to those who have fulfilled with credit the duties of hospital appointments.

Four House-Surgeons, tenable for three or six months, and Dressership to In-patients, open to all.

Dressership to Out-patients, with the privilege of competency for the Prizes above-mentioned.

The office of Resident Medical Officer, tenable for two years, with a salary of £75 for the first year, and £100 for the second year. The office of Junior Resident Medical Officer, tenable for six months.

Four Medical Assistantships, held for three months, with residence and board in the hospital for three weeks.

The office of Resident Accoucheur, tenable for six months.

The holders of all the resident offices are provided with rooms and board free of expense.

Two offices of Clinical Assistant in the Medical Out-patients' Department, each at a salary of £40.

Two offices of Clinical-Assistant in the Surgical Out-patients' Department, each at a salary of £40.

The office of Medical Registrar; salary, 25 guineas.

The office of Surgical Registrar; salary, 35 guineas.

Prosecutors of Anatomy, Ward Clerks, and Post-mortem Clerks.

#### ST. BARTHOLOMEW'S HOSPITAL.

The great city hospital has always attracted large numbers of students from all parts of the country, so that the school is very flourishing.

H.R.H. the Prince of Wales is the President of the hospital, which receives within its walls upwards of 5,000 in-patients annually, and its out-patients and casualties amount to more than 100,000 annually. It contains 650 beds, of which 403 are allotted to surgical, including ophthalmic, orthopaedic, aural, and syphilitic cases, and 247 to medical cases and diseases of women and children. One of the Assistant-Physicians sees the medical out-patients daily, between eleven and two; and one of the Assistant-Surgeons sees the surgical patients daily, between twelve and two.

Accommodation is provided for residence of students in the college connected with the institution, for which an entrance fee of 2*l.* 2*s.*, and a further payment of caution money, 3*l.* 3*s.*, is required. The cost of maintenance varies from 30*s.* to 33*s.* per week, payable in each term; and the term of residence is unlimited.

#### GUY'S HOSPITAL.

This old favourite borough school still attracts as many students as ever. The school is, we believe, one of the most popular in the metropolis, and from the excellence of

its appointments, its situation, and superior staff, it still keeps up its old renown. In special departments, Guy's is the most advanced. This hospital set the example of giving the appointments to its special departments to gentlemen not on the general staff.

Guy's is situated close to the London Bridge Railways. Hence great facilities for getting to any part of London or the country. It is quite practicable for students to reside a little distance down either of the lines that converge at this point, and thus enjoy the benefit of country air during their hospital career. For those who wish to live close to the hospital, there are many lodgings to be had at a moderate price.

#### ST. THOMAS'S HOSPITAL.

This is the borough hospital which was removed from London bridge for the Charing-cross Railway. The opening of the new buildings on the Thames Embankment, and the strengthening of the professional staff, can scarcely fail to give a new impetus to the hospital and school.

There is accommodation for residence and free maintenance in the College-house for the two house-surgeons, resident accoucheurs, one dresser, one obstetric clerk, and assistant obstetric clerk, which appointments are awarded by competition.

#### UNIVERSITY COLLEGE AND HOSPITAL.

This is situated in a very central position, near the Gower street Station of the Underground Railway, affording facilities for gentlemen residing in many parts of London. The College gives instruction in every department of knowledge, and specially prepares students for degrees in all the Faculties at the University of London. There is, however, no theological faculty, the College, like the University with which it is in intimate connection, being founded on the non-sectarian principle. The Medical Faculty and the Hospital are very complete and flourishing as educational institutions. The University College School specially prepares boys to be ready at a proper age to enter the College.

#### KING'S COLLEGE.

This College gives instruction in all the faculties, and has a Theological Department. It was established by Church of England persons, in opposition to University College, which is a non-sectarian institution. King's, then, is the Church of England College. The College is situated close to Somerset House, having a frontage on the New Thames Embankment, within a few minutes' walk of a station on the Underground Railway. There is also a junior school in connection with this College, to prepare boys to enter the College at a proper age. The Hospital is only a short distance from the College, and although small, the renown of its staff has always kept up its reputation, so that King's is one of the most popular of the medical educational institutions in London.

#### CHARING CROSS HOSPITAL.

This hospital, though one of the smaller ones, derives from its situation great advantages. It is one of the most central positions in London, where there is constant communication with every part. In connection with it the practice of the Royal Western Ophthalmic Hospital close by, affords an excellent opportunity for the study of that branch of the profession. Other special departments have been established, and the authorities seem to have the courage to establish them on a liberal basis, the hospital staff not monopolising these appointments.

#### ST. GEORGE'S HOSPITAL.

The chief advantage of this School, is its unrivalled position, at the corner of Hyde Park—perhaps the most salubrious part of the metropolis. Students can easily find lodgings within half an hour's pleasant walk. It is perhaps, the most aristocratic of the London schools, and the present staff maintain their position as worthy successors of Hunter, Brodie, and other worthies who formerly taught in it.

## MIDDLESEX HOSPITAL.

The hospital contains upwards of 300 beds, of which 184 are for surgical, and 120 for medical cases. There is a special department for cancer cases affording accommodation for thirty-three in-patients, whose period of residence in the hospital is unlimited. Wards are also appropriated for the reception of cases of uterine disease and of syphilis, and beds are set apart for patients suffering from diseases of the eye.

Special attention is bestowed on the clinical instruction of the students both in the wards and out-patients' rooms. Three clinical prizes, including the governors' prize of twenty guineas, are annually awarded to those students who pass the most satisfactory examination at the bedside, and in the *post-mortem* room. Class prizes are also given, and six resident clinical appointments are annually awarded after competitive examination, to students who have completed their education and complied with the regulations of the school. The officers thus appointed reside and board in the hospital free of expense.

The college tutor assists all general students free of charge, especially those who are preparing for examination, and his daily instruction is arranged with a view to avoid the necessity of students obtaining any private teaching apart from that of the medical school.

## WESTMINSTER HOSPITAL.

This is near the Abbey and the Houses of Parliament, and will be found convenient for all in that neighbourhood. It is well appointed in every respect, and one of the most moderate in respect to fees. The whole course of study for the usual examinations may here be completed for seventy-five guineas, payable in instalments. The perpetual fee is only eighty guineas. Resident appointments, clerkships, and dresserships are all conferred without extra payments. Suitable lodgings may be obtained in the neighbourhood, and at not more than a quarter of an hour's walk from the hospital.

## ST. MARY'S HOSPITAL.

There is a Medical School in connection with this hospital, which is located at Paddington, in close proximity to the Great Western Terminus. Students with slender purses will find the neighbourhood of the hospital a very moderate one as regards lodgings, and easy of access by omnibus and the Underground Railway to all parts of London. Three resident medical officers are appointed for twelve months, and an obstetric officer for six months, who board free of expense in the hospital. A resident registrar is also appointed from amongst the students, with a salary of £100 a-year. These appointments are awarded after competition, without additional fee.

## SCOTTISH INSTITUTIONS.

So many English students afterwards go to Scotland that in order to complete our outline, we now turn to the various bodies in Scotland, most of which are both teaching and examining bodies. First, as to the Universities. The fees for degrees in all four of the Scottish Universities are uniform—viz.: M.B., £15 15s. (being £5 5s. at each of the three examinations); C.M., £5 2s. (in addition to the fees of M.B.); M.D., £5 5s. (in addition to the fees for M.B.); and £10 3s. for Government stamp.

*University of Edinburgh.*—This is a teaching as well as a qualifying body, and the other faculties are as complete as that of medicine. The University confers the degree of M.D., and M.B., as well as that of C.M., and so affords its graduates the opportunity of obtaining, at the same time, a Surgical, in addition to the medical diploma. The C.M. is not conferred on any one who does not take at the same time the M.B. For the degrees of M.B. and C.M., four years of professional study must be completed after passing a preliminary examination recognised by the Medical Council. A degree in Arts in any British University

exempts from the preliminary examination. Of these four years, one must be passed in the University of Edinburgh, and one other either in that or some other University entitled to confer the degree of M.D.

The University recognises the courses of lectures of extra-academical teachers in Edinburgh, subject to certain regulations.

*University of St. Andrew's.*—This University confers the Degree of Master in Surgery (C.M.), as well as the Degrees of Bachelor and Doctor of Medicine. For many years the University did not require residence, and large numbers of medical men resorted to it in order to obtain the Doctorship by examination only. In this the University closely assimilated itself to the University of London, which is exclusively an examining body. The large number of practitioners who obtained the Degree after an examination extending over three or four days, attests the wisdom of a policy which was almost reversed by the University Commissioners. Only ten persons per annum can now obtain the St. Andrew's Degree without residence. There are not a few of the old graduates who look upon this policy as retrograde and illiberal. The University of London maintains its position without requiring academical residence, and no one can doubt that the University of St. Andrew's might have pursued the same course with great success, and by so doing conferred a benefit on the profession. Those who have not now fulfilled their course in a University must either go to the University of London or forego a degree. The London University compels matriculation before commencing Hospital study. Only a relaxation of this rule can secure to all who desire it the opportunity of being examined for a degree.

*University of Aberdeen.*—This is a large teaching body, as well as one entitled to confer degrees in all the faculties. The curriculum required for medical degrees is the same as that of the University of Edinburgh. Thus, four years of professional study, after passing a preliminary examination, is essential. One year must be passed at Aberdeen. The lectures qualifying for this and other examining bodies are delivered by the Professors in the University.

*University of Glasgow.*—This is a large teaching as well as examining body. The same degrees are conferred as in the Universities of Edinburgh and St. Andrew's. The course of study and regulations to be observed by candidates are the same as those of the University of Edinburgh, one year's compulsory residence at the University of Glasgow being required instead of at Edinburgh. The examinations are conducted by the Professors of Medicine, together with the three Assessors appointed by the University Court. The lectures qualifying for the degrees are delivered by the Professors in the University, and the hospital practice is attended at the Glasgow Royal Infirmary.

Now as to the Corporations.

*Royal College of Physicians of Edinburgh.*—This, like its London sister, is exclusively a licensing body, though, since the arrangement for the double qualification has been carried out, it may possess some additional control over the teaching at Surgeons' Hall. By this arrangement students who have filled the prescribed curriculum may pass the joint examination of this College and the Royal College of Surgeons, and obtain the two diplomas. They can thus at once register both a medical and surgical qualification.

The *fellowship* is conferred only by election, and no one can be ballotted for until he has been a member for one year.

The *Membership* is conferred on licentiates of a College of Physicians, or graduates of a University, who are twenty-four years of age, and satisfy the College of their knowledge of medical and general science.

THE LICENCE.—The regulations are nearly the same as those for the joint examination for the Scotch Double Qualification.

*Royal College of Surgeons of Edinburgh.*—The Fellowship is conferred only on persons who have obtained a

diploma from this or one of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, and who are 25 years of age. At the election, three-fourths of the votes are required to be in the candidate's favour, and he has to promise to maintain the privileges of the College and obey its laws. Fellows are forbidden to keep open shops, to be connected with secret remedies, or to suffer their names to be used in indelicate advertisements or publications.

**THE LICENCE.**—The regulations are nearly the same as those for the Joint Examinations, conducted by the Colleges of Physicians and Surgeons.

**Faculty of Physicians and Surgeons of Glasgow.**—This body has similar powers to those of the Royal College of Surgeons of Edinburgh, and its regulations for Licence and Fellowship correspond. It has also the same arrangement with the Edinburgh College of Physicians for a double diploma.

**The Scotch Double Qualification.**—As already stated, the Royal College of Physicians of Edinburgh has made arrangements with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, by which, after one series of examinations, the successful candidate receives two diplomas, and is thus able to register a medical and a surgical qualification under the Medical Act, thus:—

Lic. Roy. Coll. of Phys. Ed., and Lic. R. C. S. Edin., or Lic. R. Coll. of Phys. Ed., and L. Fac. Phys. and Surg. Glas., as the case may be.

The principle on which the joint examinations are conducted is a simple compromise by which the College of Physicians takes exclusive charge of the examination in medicine; the College of Surgeons or the Glasgow Faculty, as the case may be, of the examination in surgery; while the examination in subjects common to both medicine and surgery is conducted by a Board, in which each of the bodies is represented.

It is proper to state that such arrangements as these were contemplated by the Medical Act and authorised by Section XIX., while those under consideration were sanctioned by the Medical Council on the 7th August, 1859.

Candidates for the double qualification having fulfilled the prescribed curriculum are subjected to two professional examinations. The preliminary examination for future students must be passed before commencing professional study, and in other respects be in accordance with the recommendations of the Medical Council.

**Anderson's University, Glasgow.**—This is exclusively a teaching body. It offers excellent opportunities for acquiring a complete medical education, and the expenses are very much below those of any other institution. The fame of Glasgow as a place for clinical instruction has long been known, and this school affords the means of dissection, and the pursuit of other practical knowledge throughout the year. Hospital practice is attended at the Glasgow Royal Infirmary.

## SPECIAL DETAILS RESPECTING HOSPITALS AND MEDICAL SCHOOLS.

### I.—LONDON.

**ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.**—The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical out-patients, and the dressers in the special departments are chosen from the diligent students. Sixteen ward-dresserships are given annually to the students (of the second year) who pass the best examination in the subjects of study of the first and second year, or who may be otherwise specially recommended for such appointments. Other ward-dresserships may be obtained by payment of the usual fees.

Students can reside in the College subject to the College regulations.

**Foundation and other Prizes.**—The Jeaffreson Exhibition,

of the value of £20 yearly, and tenable for two years, is awarded in October, to the student who passes the best examination in the subjects of General Education. A Senior Scholarship, of the value of 50*l.*, in Medicine, Surgery, and Midwifery. A scholarship, 25*l.*, is awarded to the student placed second in this examination. A senior scholarship, 50*l.* in Anatomy, Physiology, and Botany. A Scholarship of 25*l.* is awarded to the student placed second in this examination. Junior Scholarships in the subjects of study of the first year:—1. 50*l.*; 2. 30*l.*; 3. 20*l.* The Wix Prize is awarded for the best essay on "The Connection between Revealed Religion and Medical Science." The Bentley Prize for the best report on Surgical cases, occurring in the wards of the hospital during the previous year. The Kirkes Gold Medal for Clinical Medicine. The Hichens Prize for the best examination in "Butler's Analogy." Foster prize for the best examination in Practical Anatomy (senior). The Treasurer's Prize for the best examination in Practical Anatomy (junior).

**CHARING-CROSS HOSPITAL AND COLLEGE.**—The Llewellyn Scholarship of 25*l.* is open to matriculated students who have just completed their second year. The Golding Scholarship of 15*l.* a year is open to matriculated students who have just completed their first year. The following medals are awarded annually:—The Gold Medal for General Proficiency; The Governors' Clinical Silver Medal. Silver and Bronze Class Medals, on all the subjects of the lectures. The fee for matriculation is 2*l.* 2*s.*, to be paid on entering. Medical tutor's class, one session, 2*l.* 2*s.*; two sessions, 3*l.* 3*s.*

**ST. GEORGE'S HOSPITAL.**—Perpetual pupils, who pay 100 guineas, are entitled to admissions to the medical and surgical practice; to compete for its prizes and exhibitions; to hold the appointments of house-physician and house-surgeon, assistant house-physician, assistant house-surgeon, ophthalmic and orthopædic assistant, and to become clinical clerks for two periods of three months each, and dressers for similar periods. Gentlemen are admitted to the hospital practice and lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries on payment of forty guineas at the commencement of the first winter session, forty guineas at the commencement of the second year of study, and ten guineas for each succeeding year, which entitles the pupil to hold the offices of clinical clerk and dresser for three months each, and to become a candidate for the offices of medical and surgical registrar and demonstrator of anatomy and curator of the museum. These are all salaried offices. The obstetric assistant is resident, with a salary of 100*l.* He must be a legally qualified practitioner.

**Prizes.**—The "William Brown Exhibition," of 40*l.* per annum, tenable for three years, for general fitness for the exercise of the medical profession, and for moral conduct. Sir Charles Clarke's Prize (interest of 200*l.* consols) for good conduct. The Thompson Medal, for the best clinical report of medical and surgical cases observed in the hospital during the preceding twelve months, accompanied by observations. Sir Benjamin Brodie's Clinical Prize in Surgery, for the best report of Surgical cases which have occurred in the hospital during the preceding twelve months, with notes illustrative of their pathology, diagnosis, and treatment. The Acland Clinical Prize in medicine, for the best report of Medical cases which have occurred in the hospital during the preceding twelve months, accompanied by drawings, diagrams, and observations. The Henry Charles Johnson Memorial Prize, awarded at the end of the winter session to the pupil most distinguished in Practical Anatomy, and the Treasurer's Clinical Prize.

**GUY'S HOSPITAL.**—House-physicians and house-surgeons, obstetric residents, dressers, clinical, and other clerks, are selected from the students according to merit, and without payment.

**Prizes, &c.**—Voluntary competitive examinations are held at four periods of the student's course. 1. The entrance examination (commencing this year on October 11th) comprises Elementary classics, Ancient and Modern History, and Mathematics. The candidate who distinguishes himself the most receives 25*l.*; the second candidate, 20*l.*; and the third, 15*l.* 2. At the end of the first sessional year, in all the subjects of the first year's course of study. First prize, 30*l.*; second, 25*l.*; third, 10*l.* 10*s.* 3. At the end of the second sessional year, in Medicine, Surgery, Midwifery, Anatomy, Physiology, Chemistry, and Therapeutics. First prize, 35*l.*; second, 30*l.*;

4. At the end of the third sessional year, in Medicine, Surgery, Midwifery, and Medical Jurisprudence. First prize, 40*l.*; second prize, 35*l.* Honorary certificates are given to those candidates who pass creditable examinations. At the end of the winter session a prize of 10*l.* is awarded for the best essay on a given subject with reports of cases, and another prize of 10*l.* for the best paper read before the Society.

**KING'S COLLEGE**—The physicians' assistants, the physician-accoucheur's assistant, the clinical clerks, and the house-surgeon and dressers, are selected by examination from among those matriculated students of the College who are pupils of the hospital.

**Scholarships**—Warneford Scholarships: Two of 25*l.* per annum, for three years. College Scholarships: One of 40*l.* per annum, for two years; one of 30*l.* for one year; three of 10*l.* for one year. The Daniell Scholarship, of the annual value of 20*l.* Sambrooke Registrarships, of the annual value of 50*l.* each, and tenable for two years; are open to all matriculated students who have filled any one of the higher appointments at the hospital, or who have become Associates, Leathes' Prizes, consisting of a Bible and Prayer book, as annual prizes to two matriculated students. Warneford Prizes: The sum of 40*l.* is expended in the purchase of medals and books as prizes to two matriculated medical students. Class prizes are awarded annually for proficiency in the several subjects of Anatomy, Physiology, Chemistry, Materia Medica, Surgery, Medicine, Obstetric Medicine, Botany, Forensic Medicine, Comparative Anatomy, Pathological Anatomy, Practical Physiology, and Practical Chemistry. These consist of books of the value of 3*l.* in each subject of examination. Certificates of Honour are also given. Two Medical Clinical Prizes, one of 3*l.* for the winter session, and one of 2*l.* for the summer session; and two Surgical Clinical Prizes, of the same value are given. The Todd Medical Clinical Prize consists of a bronze medal and books to the value of four guineas.

**ST. MARY'S HOSPITAL**—Four resident officers, who board free of expense in the hospital, are appointed, after competition, without additional fee. A resident registrar is also appointed from amongst the students, with a salary of 100*l.* a year.

**Scholarships, Prizes, &c.**—A Scholarship in Natural Science of the annual value of 40*l.*, tenable for three years, and an exhibition in Natural Science of the value of 20*l.*, tenable for one year, will be awarded immediately before the commencement of each winter session, by open competitive examination. A Scholarship in Anatomy of the annual value of 20*l.*, for students who have completed their second winter session; and a Scholarship in Pathology of 20*l.*, for students who have completed their third winter session. Examinations will be held and prizes awarded in the various classes of each year at the termination of both the summer and winter sessions. Two prosectors are annually appointed who each receive 5*l.* and a certificate for their services.

**MIDDLESEX HOSPITAL**—Special attention is bestowed on the clinical instruction of the students both in the wards and on patient rooms. Classes, open to all students, are held for practical instruction in the microscopic examination of healthy and diseased tissues, and also in the application of bandages and other surgical apparatus. Students are allowed to take out to read at their own homes the books from the large and carefully selected medical library of the school. Three clinical prizes, including the Governors' Prize of twenty guineas, are annually awarded to those students who pass the best examination at the bedside and the post-mortem room. Class prizes are also given, and six resident clinical appointments are annually awarded, after competitive examination, to students who have completed their education, and complied with the regulations of the school. The officers thus appointed reside and board in the hospital free of expense. The College tutor assists all general students, especially those who are preparing for examination, free of charge.

**ST. THOMAS'S HOSPITAL**—*Prizes and Appointments for the Session*.—For First-year's Students: prizes, winter, of 20*l.*, 15*l.*, and 10*l.*; summer, 15*l.*, 10*l.*, and 5*l.* For Second-year's Students: winter, 20*l.*, 15*l.*, and 11*l.*; summer, 15*l.*, 10*l.*, and 5*l.*; with the dressership and the clinical clerkships. For Third year's Students: prizes of 20*l.*, 15*l.*, and 10*l.*, and the Prosector's prize of 5*l.* The William Tite Scholarship,

founded by Sir William Tite, F.R.S., the proceeds of 1,000*l.* Consols, tenable for three years, is awarded every third year. Clinical clerks and dressers are selected according to merit. Certificates of honour are given. The dressers are provided with rooms and commons free of expense. The Grainger Testimonial Prize of 20*l.*, awarded biennially to third or fourth year's students, for the best Physiological Essay, to be illustrated by preparations and dissections. The Cheselden Medal, for Surgery and Surgical Anatomy. The Treasurer's Gold Medal, for general proficiency and good conduct. The house-physicians, house-surgeons, and resident accoucheur are chosen according to merit, with rooms and commons. Two hospital registrars, at 40*l.* per annum each, or one at 80*l.*, will be selected from gentlemen distinguished for merit.

Lectures will be delivered during the session on the Geographical Distribution of Diseases, by Mr. Alfred Haviland; and Demonstrations illustrative of the Preparations in the Museum, by the Curator, Mr. C. Stewart, besides which the arrangement for the special departments are complete.

**UNIVERSITY COLLEGE**.—*Scholarships and Exhibitions*.—The Atkinson-Morley Surgical Scholarship, of 45*l.* per annum, tenable for three years, is awarded every year for proficiency in the theory and practice of Surgery. The Sharpey Physiological Scholarship, of about 95*l.* a year, for proficiency in Biological Science. The Filliter Prize of 30*l.*, for proficiency in Pathological Anatomy. Dr. Fellowes's Clinical Medals, one gold and one silver, each winter and summer session, and certificates of honour, for reports and observations on the medical cases in the hospital. The Liston Gold Medal, and certificates of honour, for reports and observations on the surgical cases in the hospital. The Alexander Bruce Gold Medal for Pathology and Surgery. The Cluff Memorial Prize, awarded every other year for proficiency in Anatomy, Physiology, and Chemistry. Gold and silver medals, as well as certificates of honour, are awarded as class prizes. The Jews' Commemorative Scholarship of 15*l.* a year, tenable for two years' standing, may be held by students who, after obtaining it, enter the Medical Faculty.

**Entrance Exhibitions**.—Three Entrance Exhibitions of the respective value of 30*l.*, and 18*l.* per annum, tenable for two years, are awarded upon examination, to gentlemen who are about to commence their first winter's attendance in a Medical School. The next examination will be held on the 28th and 29th September, 1871.

**Analytical Chemistry**.—The Birbeck Laboratory is open daily from 9 A.M. to 4 P.M. Fees, exclusive of the expense of materials: session, 26*l.* 5*s.*; three months, 10*l.* 10*s.*; one month, 4*l.* 4*s.*

Physicians' assistants, house-surgeons, midwifery assistants, physicians' clerks, surgeons' dressers, ward clerks, and ophthalmic surgeons' assistants, are selected from the pupils without additional payment. The physicians' assistants, obstetric assistant, and house-surgeons reside in the hospital, paying for their board.

**WESTMINSTER HOSPITAL**.—In addition to the practice of the Hospital, which contains 191 beds, the pupils of this school are admitted to the practice of the Westminster Ophthalmic Hospital, and to that of the National Hospital for Epilepsy and Paralysis.

**Prize Appointments**.—A House-Physician and House-Surgeon are appointed annually, by examination, from amongst the senior students, without the payment of any fee; and these officers are provided with board and lodging free of expense. There are Medical and Surgical Registrars, each of whom receives a salary of about 50*l.* A Medical Obstetric Assistant boards and resides at the Hospital without fee.

**Prizes**.—In addition to the appointments above enumerated, there is a Scholarship of twenty guineas, in Anatomy and Physiology, a Prize of the value of 20*l.* for general proficiency, two Clinical Prizes of the value of five guineas each. Prizes are also rewarded to the most meritorious Students of the first and second years.

Further particulars may be obtained on application to Dr. Sturges, the Dean of the School.

## 2.—PROVINCIAL.

**GENERAL HOSPITAL, BIRMINGHAM**.—Physicians: Dr. Bell Fletcher, Dr. Russell, Dr. Wade, Dr. Foster. Surgeons: Mr. Baker, Mr. Pemberton, Mr. Bartlett, Mr. Goodall, Mr. Jolly. House-Physician and Medical Tutor: Dr. Greenway. House-Surgeon: Mr. May. Registrar and Pathologist: Mr. Rickards. Fees, medical and surgical practice, six

months, 10*l.* 10*s.*; one year, 15*l.* 15*s.*; perpetual, 31*l.* 10*s.* Clinical lectures are delivered by the physicians and surgeons every week during the session. Special clinical courses, with demonstrations, will also be given on the following subjects—viz., diseases of women, stethoscopy, laryngoscopy, ophthalmoscopy, dermatology, bandaging and minor surgery, and clinical microscopy. The following resident appointments, with board, lodging, and washing, are filled up from amongst the students, without extra fee—viz., resident medical assistant, tenable for twelve months; resident surgical assistant, tenable for twelve months; two resident dressers, tenable for six months. Extern clerks and dressers are also appointed without extra fee. Prizes in books or money (at the discretion of the Medical Board) to the value of 25*l.* are given annually.

**QUEEN'S COLLEGE, BIRMINGHAM.**—*Professors of the Medical Faculty.*—Winter Courses: Medicine, Dr. James Russell. Dr. Balhazar W. Foster; Surgery, Mr. Oliver Pemberton, Mr. Furneaux Jordan; Anatomy, Mr. Charles J. Bracey, M.B. Lond., and William Thomas, M.B., F.R.C.S.; Physiology, Dr. Richard Norris, Mr. T. H. Bartleet, M.B. Lond.; Chemistry, Dr. Alfred Hill, F.C.S.; Demonstrator of Anatomy, Mr. Robert Jolly, M.D., F.R.C.S.E. Summer Courses: Midwifery, Mr. John Clay, Mr. John Bassett; Diseases of Women and Children, Mr. Samuel Berry and Dr. R. C. R. Jordan; Forensic Medicine and Toxicology, Mr. Thomas Swain, and Dr. Alfred Hill; Practical Chemistry, Mr. Alfred Anderson, F.C.S.; Botany, Dr. William Hinds; Materia Medica and Therapeutics, Mr. J. St. S. Wilders and Edward Mackey, M.B. Lond.; Ophthalmic Surgery, Mr. J. Vose Solomon; Dental Surgery, Mr. Thomas Hawkins; Comparative Anatomy, Dr. Thomas Savage; Medical Tutor and Registrar, vacant.

Hospital Practice may be attended at either the General Hospital or the Queen's Hospital, which are equidistant from the College.

*Resident Students.*—Students may reside within the College, where they will be provided with rooms and board, and will be under the supervision of the Warden and Resident Tutors.

*Resident Tutors.*—The Professor of Classics, the Professor of Mathematics, and the Medical Tutor.

*Scholarships and Prizes.*—Two Warneford Scholarships, the Sands Cox Prize (value of 20*l.*), the Warden's Prize (of the value of five guineas), the Percy Prize (books of the value of five guineas), and Class Prizes, Medals, and Certificates of Honour are awarded annually.

Further information may be obtained by application to Professor Foster, M.D., 16 Temple row, Birmingham; or to Professor Furneaux Jordan, Colmore row, Birmingham.

**THE QUEEN'S HOSPITAL, BIRMINGHAM.**—Physicians, Dr. Fleming, Dr. Johnston, Dr. Heslop. Surgeons, Mr. West, Mr. Gamgee, Mr. Furneaux Jordan, Mr. J. St. S. Wilders. Obstetric Surgeon, Mr. John Clay. Dental Surgeon, Mr. Adams Parker. Resident Physician and Medical Tutor, Dr. Underhill. Resident Surgeon and Surgical Tutor, Mr. Gilbert Smith.

Clinical prizes of the value of 31*l.* are awarded annually. Composition fee for medical and surgical practice, 31*l.* 10*s.*; one year's attendance, 15*l.* 15*s.*; six months' attendance, 10*l.* 10*s.*; special department for midwifery and diseases of women, 2*l.* 2*s.*; dental fee, optional, 2*l.* 2*s.* Any further information may be obtained from Mr. J. St. S. Wilders, at the Queen's Hospital, Bath row, Birmingham.

**BRISTOL ROYAL INFIRMARY.**—Physicians: Drs. Brittan, Fairbrother, E. L. Fox, and J. Beddoe. Surgeons: Messrs. Leonard, Clark, Tibbits, and Steel. House-Surgeon: Dr. Shingleton Smith.

*Prizes.*—Suple Prize; A gold medal, value 5*l.* 5*s.*, with 7*l.* 7*s.* in money, is given annually to each of the two successful candidates in the medical and surgical examinations. Clark's Prize: The interest of about 500*l.* is given annually to the prizeman of the third year's examination at the Bristol Medical School, if educated at the Bristol Royal Infirmary.

**BRISTOL MEDICAL SCHOOL, SESSION 1871-72.**—The Winter Session will commence on Monday, October 2, 1871. Medicine, Dr. Martyn and Dr. Fox. Surgery, Mr. Coe and Mr. Tibbits. General Anatomy and Physiology, Messrs. Atchley and Steele. Descriptive and Surgical Anatomy, Mr. Lansdown and Mr. Board. Superintendence of Dissec-

tions, Messrs. Ludlow, Dobson, and Chute. Chemistry, Mr. Coomber.

The Summer Session will commence on May 1, 1872. Midwifery and Diseases of Women, Dr. J. G. Swayne. Forensic Medicine, Mr. W. P. Keall. Materia Medica and Therapeutics, Dr. G. F. Burder. Botany, Mr. A. Leipner. Practical Chemistry, Mr. Coomber. Pathological Anatomy, Dr. Martyn and Dr. Fox. Comparative Anatomy, Mr. Atchley.

Medical and Surgical Hospital Practice and Clinical Lectures are attended at the Royal Infirmary or at the General Hospital.

**BRISTOL GENERAL HOSPITAL.**—The Hospital contains 140 beds. Physicians, Dr. Martyn, Dr. Burder, Dr. Frigg. Surgeons, Mr. Coe, Mr. Lansdown, Dr. H. Marshall, Mr. G. F. Atchley. Physician-Accoucheur, Dr. Swayne. Two Scholarships of 15*l.* each are awarded annually. Also a Scholarship, called the Sanders Scholarship, for the study of Medicine and Surgery, being the interest of 500*l.* (to be given annually), bequeathed to the Hospital by the late J. N. Sanders, Esq.

Resident Pupils (including board, lodging, and washing), 100*l.* for the first year, 60*l.* for each subsequent year. Or for five years, with apprenticeship to the Hospital, 260*l.*

**ADDENBROOKE'S HOSPITAL, CAMBRIDGE.**—Clinical Lectures in connection with the Cambridge Medical School are delivered at this hospital twice a week during the academical year.

**LEEDS SCHOOL OF MEDICINE.**—The Hardwick Clinical Prize, value 10*l.*, is conferred annually upon the most deserving student who exhibits a satisfactory proficiency in Clinical Medicine. The Surgeons' Clinical Prize, value 10*l.*, given by the surgeons of the hospital, is conferred annually on the most deserving student who exhibits a proficiency in Clinical Surgery. In addition to the silver medal awarded in Medical Jurisprudence, there is a prize of 10*l.*, for which a special examination is annually held. Arrangements have been made for teaching Practical Surgery and Practical Physiology in accordance with the new regulations of the Royal College of Surgeons. In the infirmary there are six clinical clerkships and eight dresserships. Four resident house-surgeons are chosen from the senior students; board and residence free. Besides the Infirmary there is a large Dispensary, and a Fever Hospital; both are in the town and open to students attending the School.

**LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.**—Scholarship, value 42*l.*, consisting of a gold medal, value 10*l.* 10*s.*, and six months' free board and residence, with dressership and clerkship in the Royal Infirmary. Four Exhibitions, value 31*l.* 10*s.* each, consisting of free board and residence in the Royal Infirmary for six months, with dresserships, on award of the Medical Board. Six dressers and six clinical clerks are elected quarterly. Pupils of the infirmary are admitted to learn Pharmacy in the dispensing department for six months. The surgeons of the infirmary will award, in May, 1872, a prize of the value of 5*l.*, for the best report of twelve surgical cases occurring in the infirmary.

**LIVERPOOL NORTHERN HOSPITAL.**—146 beds. A special ward for the diseases and accidents of children. Clinical Lectures are regularly delivered by the physicians and surgeons during the winter and summer sessions. Instruction in Morbid Anatomy is given by the medical staff. A class will be formed for instruction in bandaging and the minor operations of surgery. Clinical clerkships and dresserships are open to all the students, without additional fee. Clinical prizes will be awarded at the termination of the winter session.

**LIVERPOOL SOUTHERN HOSPITAL.**—110 beds. Hospital attendance: three months, four guineas; six months, seven guineas; one year, ten guineas; perpetual, twenty-five guineas. The practice of this hospital is recognised by the Royal Colleges of Physicians and Surgeons. Students can board in the house, and are admitted at any time, on application to Dr. Little at the hospital. Clinical Lectures are delivered weekly by the physicians and surgeons. In 1870 there were 1,487 in-patients, and 4,067 out-patients. In a few months the new hospital will be ready, in which

there will be upwards of 200 beds, and in which students can reside.

**MANCHESTER ROYAL SCHOOL OF MEDICINE.**—Connected with this School are Museums of Human and Comparative Anatomy, and *Materia Medica*, and a Chemical Laboratory. In addition to three scholarships, of the value respectively of 20*l.*, 15*l.*, and 10*l.*, for perpetual students, prizes for general proficiency have been substituted for class prizes, in accordance with the suggestions issued by the Royal College of Surgeons. At the end of the sessions, certificates of honour will be awarded for regularity of attendance upon lectures, and general good conduct. The Oxford Middle-Class Examinations (Senior), and the Matriculation of the London University, both of which are held during the summer months at Manchester, are recognised as evidence of previous education. The lectures qualify for examination at the Royal College of Surgeons and the Apothecaries' Society. The students of this school are admitted to the degrees of Medicine, and for the honours, exhibitions, and scholarships conferred by the University of London. The composition fee of 42*l.* may be paid in two instalments. The composition fee for the hospital has been reduced to 42*l.*, including dresserships.

**UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.**—Four Scholarships of 25*l.* a year, in the University of Dublin, tenable for four years by students pursuing their medical studies in the University or at Newcastle, and not of sufficient standing to proceed to a licence in medicine. A Scholarship will be awarded in October next. Dickinson Memorial Scholarship, 15*l.*, for general proficiency. Two resident clinical clerks, four resident dressers and four non-resident dressers are appointed half-yearly, apartments and board free.

**NEWCASTLE-ON-TYNE INFIRMARY.**—230 beds. Medical and Surgical Clinical Lectures are delivered, and clinical instruction is given in the wards. There is a special ward for diseases of the eye. Physicians: Dr. Charlton, Dr. Embleton, and Dr. Philipson. Surgeons: Dr. Heath, Mr. Russell, Dr. Arnison, and Mr. L. Armstrong. Assistant-Surgeons: Mr. A. Bell, Dr. Hume, Mr. J. Hawthorn, and Mr. C. S. Jeaffreson. Two resident clinical clerks, four resident dressers, and four non-resident dressers are nominated by the Medical Board half-yearly, and, if approved, are appointed by the House Committee. The clinical clerks and resident dressers are provided with apartments and board free. These appointments are made without any extra fee.

**NORFOLK AND NORWICH HOSPITAL.**—155 beds. One year's attendance recognised by examining boards. Pupils resident and non-resident. Physicians: Dr. Copeman, Dr. Eade, and Dr. Bateman. Surgeons: Mr. Nichols, Mr. Firth, and Mr. Cadge. Assistant-Surgeons: Mr. Crosse and Mr. Williams.

**SHEFFIELD SCHOOL OF MEDICINE.**—The Infirmary contains 150 beds; a Museum of Pathology, Library, and Post-mortem Theatre, with microscopes, and all the appliances for clinical research. Perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, 40*l.* Prospectuses and all further information may be obtained upon application to the Hon. Secretaries, Dr. Frank Smith and Mr. A. Jackson.

**SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.**—100 beds. Physicians: Drs. J. C. Hall, J. Law, and S. Mitchell. Surgeons: Messrs. Chesman, A. Jackson, and Keeling. Accoucheurs: Drs. Mason and Hime.

**SHEFFIELD HOSPITAL FOR WOMEN.**—Medical Officers: Dr. Jackson, Dr. Keeling, Dr. Hime, and Mr. F. Woolhouse. The hospital contains twelve beds, devoted more especially to cases requiring obstetric operations and difficult midwifery. Students can attend the practice of the hospital, and be supplied with cases of midwifery, on the payment of a fee of 1*l.* 1*s.*

**SOUTH STAFFORDSHIRE GENERAL HOSPITAL, WOLVERHAMPTON.**—One year's attendance recognised by examining boards. Pupils resident and non resident.

**YORK COUNTY HOSPITAL.**—Established 1740; rebuilt 1851. Physicians: Drs. G. Shann and W. Matterson. Surgeons: Messrs. W. D. Husband, G. Hornby, and R. Hewitson. House Surgeon: Mr. O. Baker.

## CHANGES IN THE ENGLISH CLINICAL HOSPITALS AND MEDICAL SCHOOLS.

THE following changes in the hospitals and medical schools have taken place since the issue of our last Student's Number:—

**ST. BARTHOLOMEW'S HOSPITAL.**—Sir James Paget has resigned the post of surgeon to the hospital, and been appointed consulting-surgeon; Mr. Callender thus became surgeon, and Mr. Morratt Baker was appointed as assistant-surgeon. Mr. Luther Holden having resigned the chair of Anatomy, Mr. Callender and Mr. Thomas Smith succeed. Dr. Russell has succeeded the late Dr. Matthiessen in the chair of Chemistry and Practical Chemistry. Mr. Willett succeeds Mr. Langton and Mr. Marsh in teaching Operative Surgery, and Mr. Symons is appointed demonstrator of Practical Physiology. Dr. Claye Shaw has been appointed lecturer on Psychological Medicine in the room of Dr. Thorne Thorne.

**CHARING-CROSS HOSPITAL.**—The death of Dr. Hyde Salter, the senior physician to the hospital, and lecturer on Medicine, has caused several changes. Dr. Pollock and Dr. Silver have been promoted to full physicianships; and Dr. Douglas Powell has been appointed assistant-physician. Mr. Fairlie Clark has been appointed assistant-surgeon.

**ST. GEORGE'S HOSPITAL.**—Mr. Pick will take part of the course of Surgery with Mr. Holmes, and succeed Mr. Rouse as teacher of Operative Surgery. Dr. Lockhart Clarke will lecture on Diseases of the Brain and Spinal Cord. Mr. Dalby has been appointed lecturer on Aural Surgery.

**GUY'S HOSPITAL.**—Dr. Pavy has been appointed to the full physicianship, and Dr. Pye-Smith has been appointed assistant-physician. Mr. Cock has resigned office as senior surgeon and has been appointed consulting-surgeon; Mr. Bryant, late senior assistant-surgeon, has become full surgeon; Mr. Howse and Mr. Davies-Colley have been appointed assistant-surgeons. Dr. Hilton Fagge will assist Dr. Moxon in the course of Pathological Anatomy. Dr. Thompson Dickson has been appointed lecturer on Mental Diseases.

**KING'S COLLEGE.**—Mr. Bloxam has succeeded the late Dr. Miller as professor of Chemistry. Dr. Edgar Sheppard has been appointed professor of Psychological Medicine. Mr. Henry Smith has become full surgeon to the hospital. Mr. Wood succeeds Mr. Partridge as one of the lecturers on Clinical Surgery.

**THE LONDON HOSPITAL.**—Dr. Hughlings Jackson and Dr. Langdon Down have been promoted to the full physicianship. Dr. Prosser James has succeeded Dr. Down in the chair of *Materia Medica* and Therapeutics. Dr. Meymott Tidy has succeeded Dr. Prosser James as co-lecturer on Forensic Medicine with Mr. J. E. D. Rodgers.

**ST. MARY'S HOSPITAL.**—The time of office has expired of Dr. Sibson, physician, Mr. Samuel Lane, surgeon, and Dr. Tyler Smith, obstetric physician. Dr. Broadbent has been promoted to the full physicianship. Dr. J. A. Nunneley has been appointed assistant-physician. Mr. E. Owen has been appointed assistant-surgeon; and Dr. A. Meadows obstetric physician and lecturer on Midwifery. Mr. Norton takes the whole course of Anatomy, Mr. Gascoven having succeeded Mr. Spencer Smith as Mr. J. R. Lane's colleague in the chair of Surgery. Mr. Wright takes the chair of Chemistry and Practical Chemistry. Dr. Broadbent assists Dr. King Chambers in that of Medicine. Dr. Nunneley takes Histology in place of Dr. Lawson. Dr. Cheadle succeeds Dr. F. Payne on Pathology. Mr. Howard Hayward has succeeded Mr. Sercombe as lecturer on Dental Surgery.

**THE MIDDLESEX HOSPITAL.**—Dr. Murchison having gone to St. Thomas's Hospital, is succeeded in the chair of Medicine by Dr. Greenhow. Dr. Burdon Sanderson has vacated the office of assistant-physician; and Mr. Henry Arnott, having been appointed to St. Thomas's Hospital, has retired from the office of assistant-surgeon. Dr. Cayley and Dr. John Murray have been appointed assistant-physicians; and Mr. Henry Morris assistant-surgeon. Mr. Lowne takes the chair of Physiology in the room of Dr. Ferrier. Dr. Murie will lecture on Comparative Anatomy in place of Dr. Spencer Cobbold. Mr. Hulke, Mr. Lawson, and Mr. Morris will jointly teach Operative Surgery.

**ST. THOMAS'S HOSPITAL.**—By the resignation of Mr. Solly, Mr. Sidney Jones has become full surgeon. Mr. Croft attained the same rank on the enlargement of the staff. Dr.

Murchison, Dr. John Harley, and Dr. Payne have been added to the medical, and Mr. MacCormac, Mr. F. Mason, and Mr. Henry Arnott the surgical, staff. Mr. Liebreich has been appointed ophthalmic surgeon and lecturer. Dr. Murchison will share the lectures on Medicine with Dr. Peacock, Mr. Jones those on Surgery, with Mr. Le Gros Clark, Dr. Harley those on Physiology with Dr. Ord, Mr. Mason those on Anatomy with Mr. W. W. Wagstaffe, and Mr. MacCormac those on Practical Surgery with Mr. Croft.

UNIVERSITY COLLEGE.—Dr. Bastian has become full physician, Mr. Berkeley Hill and Mr. Christopher Heath full surgeons. Mr. Marcus Beck has been added to the chair of Practical Surgery. Dr. Roberts has been appointed assistant-professor of Clinical Medicine.

WESTMINSTER HOSPITAL.—Mr. Legge Pearse has succeeded Mr. Mason as surgeon and lecturer on Anatomy, and Mr. Davy and Mr. Cooke have become assistant-surgeons, Dr. Anstie undertakes the whole of the lectures on Medicine. Mr. Hillman has retired from the office of surgeon. In consequence of the retirement of Mr. Mason, Mr. Hothouse is the sole occupant of the lectureship on Surgery. Dr. R. J. Lee succeeds Dr. Sturges as the co-lecturer with Dr. Gibb on Medical Jurisprudence. Dr. Sturges takes the chair of Materia Medica. Dr. Maclure, the lecturer on Physiology, will also teach Practical Physiology.

At QUEEN'S COLLEGE, Birmingham, Mr. J. F. West has retired from the lectureship on Anatomy. Mr. Jolly has been appointed surgeon to the General Hospital; and Mr. John Clay obstetric surgeon to the Queen's Hospital.

In the BRISTOL MEDICAL SCHOOL, Mr. Tibbits has retired from the lectureship on Anatomy, and has taken the place of Mr. Crosby Leonard as lecturer on Surgery in conjunction with Mr. Coe. Mr. E. C. Board has become lecturer on Anatomy in place of Mr. Tibbits, and is succeeded as lecturer on Forensic Medicine by Mr. Keall. Dr. E. Ludlow has been appointed assistant-physician, and Mr. Board assistant-surgeon, to the Royal Infirmary.

In the LEEDS SCHOOL OF MEDICINE, Mr. Wright and Mr. Walker succeed Mr. Hall and Mr. Jessop as lecturers on Physiology. Mr. S. Hey retires from the lectureship on Surgery; and Mr. Jessop is appointed one of the lecturers. Mr. J. A. Nunmeley gives instruction in Aural Diseases. Dr. Chadwick has resigned the post of physician to the Infirmary, and has been appointed consulting-physician; Dr. J. E. Eddison has been appointed physician.

Dr. Caton has been appointed demonstrator of Practical Physiology in the LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE. Dr. Inman has resigned the office of physician to the Liverpool Royal Infirmary, and has been succeeded by Dr. Waters.

In consequence of the death of Mr. Dunville, Mr. Bowring, lately dispensary surgeon, has become full surgeon to the MANCHESTER ROYAL INFIRMARY.

In the UNIVERSITY OF DURHAM COLLEGE OF MEDICINE at Newcastle, Dr. Arnison lectures (in conjunction with Dr. Humble) on Materia Medica in place of Botany.

## SCOTTISH HOSPITALS AND MEDICAL SCHOOLS.

UNIVERSITY OF EDINBURGH, 1871-72.—Principal, Sir Alex. Grant, Bart., LL.D.—The Session will be publicly opened with an Introductory Address by the Principal, on Wednesday, November 1, 1871. *Faculty of Medicine:* Materia Medica, Professor Christison, M.D.; Chemistry, Professor Crum-Brown, M.D.; Surgery, Professor Spence; Institutes of Medicine or Physiology, Professor Bennett, M.D.; Midwifery and Diseases of Women and Children, Professor Simpson, M.D.; Clinical Surgery, Professor Lister; Clinical Medicine, Professors Bennett, Laycock, MacLagan, and Sanders; Anatomy, Professor Turner, M.B.; Natural History, Professor Wyville Thomson; Practice of Physic, Professor Laycock, M.D.; General Pathology, Professor Sanders, M.D.; Anatomical Demonstrations, Professor Turner; Botany, Professor Balfour, M.A., M.D.; Medical Jurisprudence, Professor MacLagan, M.D. The Lectures on Botany and Medical Jurisprudence are given in the Summer Session. During the Summer Session, Lectures will be given on the following subjects: Botany, Professor Balfour; Practical Physiology,

including Histology, Professor Bennett; Medical Jurisprudence, Professor MacLagan; Clinical Medicine, Professors Bennett, Laycock, MacLagan, and Sanders; Clinical Surgery, Professor Lister; Anatomical Demonstrations, Professor Turner; Practical Chemistry, under the direction of Professor Crum-Brown; Practical Anatomy, under the superintendence of Professor Turner; Natural History, Professor Wyville Thomson; Medical Psychology and Mental Diseases, with practical instruction at an Asylum, Professor Laycock; Operative Surgery, Professor Spence; Practical Pathology, Professor Sanders.

SCHOOL OF MEDICINE, EDINBURGH.—The Practical Anatomy Rooms and Chemical Laboratories open on Monday, October 2. The Introductory Address will be delivered by Mr. Annandale, on November 1. *Lectures: Winter Session, Surgery, Dr. P. H. Watson, Dr. Joseph Bell, Mr. Annandale; Chemistry (Lectures, Practical Chemistry, Analytical Chemistry), Dr. Stevenson Macadam; Midwifery and Diseases of Women and Children, Dr. Matthews Duncan; Physiology (Royal Infirmary), Dr. Arthur Gamgee; Clinical Medicine (Royal Infirmary), Drs. Haldane, Balfour, Stewart, and Dr. Matthews Duncan (for Diseases of Women); Clinical Surgery (Royal Infirmary), Mr. Annandale; Anatomy (Lectures, Anatomical Demonstrations, Practical Anatomy), Dr. P. D. Handyside; Medical Jurisprudence, Dr. Littlejohn, Practice of Physic, Dr. Rutherford Haldane; General Pathology, Dr. John Wylie. *Summer Session, 1872:* Classes open on Wednesday, May 1. *Materia Medica and Therapeutics, Dr. Thomas R. Fraser; Pathological Anatomy and Histology, Dr. John Wylie; Midwifery and Diseases of Women and Children, Dr. Keiller and Dr. Angus Macdonald; Medical Jurisprudence (Royal Infirmary), Dr. Littlejohn; Clinical Medicine (Royal Infirmary), Drs. Haldane, Balfour, Stewart, and Dr. Matthews Duncan (for Diseases of Women); Clinical Surgery (Royal Infirmary), Mr. Annandale; Anatomy (Practical Anatomy, Anatomical Demonstrations), Dr. P. D. Handyside; Chemistry (Practical Chemistry, Analytical Chemistry), Dr. Stevenson Macadam.**

UNIVERSITY OF ABERDEEN—FACULTY OF MEDICINE.—*Winter Session, commencing on Wednesday, October 26—*Anatomy, Professor Struthers, M.D., £3 3s.; Practical Anatomy and Demonstrations, Professor Struthers and the Demonstrator, £2 2s.; Chemistry, Professor Brazier, £3 3s.; Institutes of Medicine, Professor Ogilvie, £3 3s.; Surgery, Professor Pirrie, £3 3s.; Practice of Medicine, Professor Macrobin, M.D., £3 3s.; Midwifery and Diseases of Women and Children, Professor Inglis, £3 3s.; Zoology, with Comparative Anatomy, Professor Nicol, £3 3s.; Medical Jurisprudence, Professor Ogston, £3 3s. *Summer Session commencing on the first Monday in May—*Botany, Professor Dickie, £3 3s.; *Materia Medica* (100 Lectures), Professor Harvey, £3 3s.; Practical Anatomy and Histology, Professor Struthers, and the Demonstrator, £2 2s.; Practical Chemistry, Professor Brazier, £3 3s.; Zoology, with Comparative Anatomy, Professor Nicol, £3 3s.

UNIVERSITY OF GLASGOW—FACULTY OF MEDICINE.—The Classes open for the Winter Session on Tuesday, October 31, 1871, when an Introductory Lecture will be given by Professor Dickson. Chemistry, Practical Chemistry, and Chemical Laboratory, Dr. Anderson, £3 3s.; Practice of Physic, Dr. Gairdner, £3 3s.; Anatomy, Anatomical Demonstrations, and Practical Anatomy, Dr. Allen Thomson and Demonstrator, £3 3s.; *Materia Medica*, Dr. Cowan, £3 3s.; Forensic Medicine, Dr. Rainy, £3 3s.; Surgery, Dr. Macleod, £3 3s.; Midwifery, Dr. Leishan, £3 3s.; Institutes of Medicine, Dr. A. Buchanan, £3 3s.; Clinical Medicine and Clinical Surgery, Physicians and Surgeons of Royal Infirmary.

GLASGOW ROYAL INFIRMARY.—Physicians, Drs. Steven Perry, McCall Anderson, Scott Orr, W. J. Gairdner, and MacLaren; Surgeons, Drs. Dewar Macleod, Buchanan, Watson, and Morton; Pathologist, Dr. Joseph Coats. Beds, 533. The valuable Pathological Museum is open to all Students who desire to examine the Preparations. Five Physicians' and five Surgeons' Assistants perform the duties of House-Physicians and House-Surgeons. These offices, held for one year, are open to Students of the fourth year. They are lodged and boarded in the Hospital for £25 per annum. Dressers to the Surgical Wards and Clerks to the Dispensary are appointed without fee.

ABERDEEN ROYAL INFIRMARY.—Contains about 300 beds. Consulting Physicians, Drs. A. Harvey, J. W. F. Smith, R. Beveridge; Surgeons, Messrs. W. Pirrie, D. Kerr, D. Fiddes, and A. Ogston; Ophthalmic Surgeon, Dr. Alex. D. Davidson;

Pathologist, Dr. James Roger; Dental Surgeon, Mr. Williamson; Resident Superintendent and Apothecary, Dr. R. Rattray; Resident Assistant-Physician, Mr. R. W. Reid; Resident Assistant-Surgeon, Mr. R. J. Garden; Pathologist and Curator of Museum, Dr. J. Rodger; Treasurer and Secretary, Mr. W. Carnie.

ABERDEEN OPHTHALMIC INSTITUTION, DISPENSARY COURT, GUESFRON.—Surgeon, Dr. A. D. Davidson. No fee charged to students. Daily at 2.30 p.m.

THE ABERDEEN ROYAL LUNATIC ASYLUM.—Contains about 450 beds. Physician and Clinical Teacher, Dr. Jamieson.

ROYAL INFIRMARY, EDINBURGH.—Beds are set apart for Clinical Instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in all departments. No fees are payable for any medical or surgical appointment. The following appointments are open to all students and junior practitioners holding the hospital ticket during the period over which the appointment extends:—1. Four resident physicians and four resident surgeons are appointed and live in the house free of charge. Candidates must be registered as legally qualified practitioners. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident clinical clerks are appointed by the physicians and surgeons, for such periods and under such conditions as they deem expedient. 3. Dresserships: Each surgeon appoints from four to nine dressers, the appointment being for six months. 4. Assistants in the Pathological Department are appointed by the pathologist.

ANDERSON'S UNIVERSITY, GLASGOW.—The fees for all the lectures and hospital practice required of candidates for a diploma of physician or surgeon, including matriculation fees and parts for dissection, do not exceed £50. Students attending the medical classes have the opportunity of witnessing the practice of the following hospitals:—Glasgow Royal Infirmary, Glasgow Dispensary for Skin Diseases, Glasgow Eye Infirmary, Glasgow Maternity Hospital and Dispensary for Diseases of Women and Children, Glasgow Royal Asylum, Glasgow Lock Hospital, Ophthalmic Institution for Injuries and Diseases of the Eye.

GENERAL FEE FOR ALL LECTURES AND HOSPITAL PRACTICE REQUIRED FOR THE USUAL DIPLOMAS.

MEDICAL EDUCATION IN IRELAND.

THE CAREER OF THE IRISH STUDENT.

THE practice of the Profession in Ireland, though not nearly as remunerative as in England, still affords a certain prospect to any Medical man who is content with modest independence. Irish Medical men pride themselves on holding a higher social position than the English general Medical practitioner. They are entitled to meet the gentry of their locality on terms

of equality, and it is not necessary or usual for them to endanger their prestige by the adoption of the trading or Christmas bill system which obtains elsewhere. In fact, what they lose in income they gain in rank.

In order to put the career of the Irish Student as plainly as possible, we narrate the progress of an ideal person, from the day on which he takes his first step towards medicine to the hour of his issue from the cocoon of studentship, a fully-developed surgeon.

The parents and guardians of Master Robert Sawyer have, after much discussion, decided that he shall be a doctor. He has had a moderate amount of schooling, at least the very moderate amount which is essential for the Medical preliminary examinations, and his father is ready to expend about £130 on his Medical education, that sum being divided over four years, or paid down in order to secure the advantage of a considerable saving.

THE CHOICE OF SCHOOLS AND COLLEGES

will depend on various circumstances, and on the aspirations of Master Sawyer. If he's intended to make a fortune and enlighten his generation as a metropolitan practitioner, and if money and education are plenty, he will probably take University degrees in Arts and in his profession. If the attainment of good professional rank on moderate terms be desired, the College of Surgeons and College of Physicians will serve every purpose.

The choice of a School, Hospital, and College having been made, Master—now *Mister*—Sawyer is perhaps sent to those to pass his

PRELIMINARY EXAMINATION

in general education, but if he be either lazy or ignorant, he may adjourn that unpleasant process, *de die in diem*, until the eve of his final qualification as a Surgeon, when, if he does so, he will find himself in possession of a mental muddle of latin and physic. The preliminary examination is, however, not to be feared.

The preliminary examination (of the subjects of which details will be found in the official regulations of each College) having been passed or postponed, Mr. Sawyer comes to town to begin work.

He may do so either (1.) on his own account, or (2.) he may become voluntarily a pupil of some Medical man, usually a teacher or hospital surgeon, who can assist him in his student course. This is by no means a requirement of any of the Colleges; it is purely a matter of option. Should the student pursue the first course, he usually comes to town, takes a lodging close to his School and Hospital, either by himself or in companionship with some *chum*, and either arranges to maintain himself or to board with his landlady. There is, of course, every degree of expense and comfort, but we should say that reasonable yet frugal living may be had in Dublin at about 10s. per week for lodging, and £5 to £6 per month for maintenance.

We would here, as a matter of private judgment, remark that it is better for parents to have board provided on a good substantial scale by the house. Young men are too apt to spend their money on luxuries or extravagancies, and make up the deficit by using insufficient food, to the great injury of the health.

COST OF EDUCATION.

Should the student proceed on his account, the lectures necessary for the L.R.C.S.I. will amount to £65; hospital attendance about £25; lying-in hospital from £4 4s. to £7 7s. These, with the diploma fee of £26 5s., represent the essentials. The sum of £52 10s., paid down at the commencement, is taken by the College of Surgeons as payment in full for all lectures requisite, and all the hospitals allow a considerable discount. Thus, the absolute payment will amount to somewhere about £33, taking the minimum mode of payment. In

addition to this sum are to be considered the payments for "grinding" or "coaching," as the Londoners call it, a process by no means necessary to any industriously inclined student, particularly under the new and more practical *régime*, where "tips" will be less useful than the practical knowledge and the fall of the mere coached be rendered probable by being asked to put his ideas on paper, examine his patient, make his diagnosis, and order his prescription. The fixed sum is at present, for private teaching, £15 15s. for the surgical and medical qualifications, and £5 5s. for pharmacy, &c. Should the candidate "grind" for the army and navy examinations, a fee varying from £10 10s. to £21 is, we believe, usual. Should the candidate perform operations on the subject as a practice, they will cost something extra. So, that, assuming the extras or voluntary costs are incurred, the total will vary say from £114 to £120 on a moderate scale; it is of course to be expected that pupil holders should have some extra payment, we therefore, might name for them 140 guineas.

If Mr. Sawyer becomes an apprentice, he need trouble himself nothing about his payments. If he is his own manager, he must enter his name with the Secretaries of the School and Hospital, and pay for the Lectures and Hospital he intends to take out. If he is wise he will not adjourn the majority of his lectures, as he may, to the next year, but will take in his first year a full third of his curriculum. He is supposed to pay the Professor's fee or Hospital fee in full on entering his name, but few students do so, and many, we are sorry to say, are in the habit of entering for the minimum allowable number of lectures, and paying the minimum allowable proportion of the fee, putting off the attendance perhaps for ever, certainly until the last moment, and adjourning the payment until they must take up the certificates.

The entry of names and commencement of study is supposed to date from the 1st of October in each year, but really does date from the 1st of November, and may be delayed by the dilatory until the 25th of the same month.

Mr. Sawyer then begins work, attending Hospital each morning at nine o'clock, and occupying his day from half-past eleven to five between lectures and dissections. His holidays—if the term be not ignoble—are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of July.

The progress of each year is the same, except that he usually devotes more attention to "grinding," dissection, and hospital dresserships, and less to lectures in his latter years of study, and after the expiration of his third session, his student-life, whether it begin in laziness and end in hurry and incompetency, or whether it commence in diligence and end in the confidence of proficiency, ends with the last examination, and he goes forth into the world either an ignoramus or a reliable surgeon, whichever his choice may have been.

#### PRIVATE TEACHING, OR "GRINDING."

THE classes for private instruction, or "grinding," as it is technically and generally called, are carried on in Dublin with universality and success.

As a rule, all private teachers are connected with schools of medicine, and are in every respect highly qualified, many of them being also hospital physicians or surgeons, and therefore in a position to afford the special advantages in the way of clinical instruction to their pupils.

Grinding is followed in two methods—namely, on what are commonly known as the "public" and the "private" plans. In the former, a number of gentlemen, varying in different schools from two to four, associate themselves into a firm, or co-partnership, and each man, selecting particular branches, gives instruction in those only. For these classes a pupil may enter at any period of his course, by payment of a certain sum; but as the amount demanded generally is

the same at whatever period of his course the student joins the class, and as he is taught for it until he obtains his degrees, it is usual to enter as early as possible, so as to secure the largest amount of instruction; but while there can be no objection to entering the name at the earliest period, we strenuously advise the student not to devote himself to "the grind" for his first, or even for his second, year of study, but to apply himself to his hospital and dissecting.

As an example of the method pursued with regard to these "public grinds," we cannot do better than give the following extract, treating on the subject, from the book of instructions and information for students, issued by the Professors of the School of Surgery of the Royal College of Surgeons:

"In connection with the School of the College, for many years four of the senior demonstrators have jointly instructed private classes in all the subjects required for the professional examinations of the licensing bodies.

"In these classes, students are taught so as to insure that the subject shall be thoroughly understood by them.

"They are divided into senior and junior, according to the year of study, capacity, and diligence of the pupils.

"The subjects are—

"Practice of Medicine, Midwifery, and Surgery.

"Anatomy and Physiology.

"Materia Medica, Botany, and Chemistry.

"At least four classes are held daily (besides those for junior) at such times as do not interfere with the lectures at the School, each lasting for one hour—part of these classes being in the evening, for those who cannot otherwise attend. The fee is £13 18s., half of which is paid at the time of entry, the remainder when the diploma or degree is obtained.

"Should Materia Medica, Botany, and Chemistry not be required, £15 15s. for all the other classes divided in a similar manner.

"The fee for Materia Medica alone is £5 5s.

"For those who have already obtained professional qualifications, there are classes held for the army and navy medical competitive examinations, when special instruction is given in all the subjects required. Fee for these classes varies from £10 10s. upwards, according to the length of time required."

"Private grinding" is simply an arrangement quite independent of the other. A student who may, or may not, be a member of another class, wishes for instruction; he goes to a "grinder," who, for a sum of, usually, £3 3s. per month, instructs him in the required branches of his profession. As a rule, each teacher devotes himself to particular subjects: thus, one gentleman grinds in, perhaps, Anatomy, Physiology, Surgery, and Medicine, another in Surgery alone, whilst a third will teach Chemistry, Botany, and Materia Medica.

In some schools slight differences of system are obtained. thus, a pupil may enter for the subjects he requires by paying a fixed sum, which entitles him to attend for the length of a session, but gives him no further claim on the attention of his grinder.

Each of these plans will be perceived to have its own particular advantages. By entering for public grinding, a pupil, on the payment of a moderate sum, secures that he shall be taught all his necessary subjects; while, on the other hand, if he enters for private grinding, he may, from being in a smaller class, secure a larger amount of individual attention; but does so at an increased expense, and must pay separately for the various branches of his teaching.

It does not require a very arithmetical head to see the difference between paying—say, £15 15s. for being taught for four years at least, in Anatomy, Physiology, Medicine, and Surgery, and paying £3 3s. per month for instruction in Anatomy and Physiology, and the same for Surgery or Medicine, or that the instruction obtained by a private or personal catechism is more valuable than in a public class.

The following list of the principal medical tutors in Dublin does not purport to be altogether comprehensive, for although it embraces the names of most of the gentlemen best known as "grinders," there are many men—such, for instance, as professors in the different schools of medicine, who give a limited amount of instruction in their own peculiar subjects."

In the School of the College of Surgeons, the four senior demonstrators are associated together for the purposes of private teaching, each gentleman giving instruction in special branches.

Mr. Croly, } in Surgery, Anatomy, Physiology,  
Dr. Stoney, } and Medicine.  
Dr. Stoker, }  
Dr. Kilgarriff } Materia Medica, Chemistry, and  
Botany.

Dr. Ormsby also teaches several of the above subjects.

In the Trinity School—

Dr. Foot, } Anatomy, Physiology, Surgery, and  
Dr. Finney, } Medicine.  
Dr. Little, }  
Dr. W. Smith—Chemistry and Materia Medica.  
Dr. Collins, } Anatomy, Physiology, Surgery, and  
Medicine.

In the Carmichael School—

Dr. Corley, } Anatomy, Physiology, Surgery, and  
Dr. Kelly, } Medicine.  
Dr. Cameron, } Materia Medica, Chemistry, and  
Botany.

In Stevens' Hospital and School—

Mr. Swan,  
Dr. Bookey, } Chemistry, Botany, and Materia  
Dr. Bell, } Medica.

In Catholic University private teaching is amply provided for by instruction given by the Demonstrators in the School.

In Ledwich School—

Dr. Ledwich and  
Dr. Mason, assisted by  
Dr. Ward,  
Dr. Corry,  
Dr. Battersby.

## REGULATIONS AND BYE-LAWS OF LICENSING BODIES IN IRELAND.

### UNIVERSITY OF DUBLIN.

The following Degrees and Licences in Medicine and Surgery are granted by the University of Dublin:—

1. Bachelor in Medicine. 2. Doctor in Medicine. 3. Master in Surgery. 4. Licentiate in Medicine. 5. Licentiate in Surgery.

#### Matriculation.

Every student must be matriculated by the senior lecturer, for which a fee of five shillings is payable; but he need not have his name on the College books, or attend any of the academical duties, unless he desire to obtain a Licence or Degree in Medicine or Surgery. No student can be admitted for the Winter Courses after the 25th of November.

#### QUALIFICATION FOR DEGREES AND LICENCES.

##### Bachelor in Medicine.

Candidates must be graduates in Arts, and may obtain the degrees at the same commencements as the B.A., or at any subsequent one. The medical education of a Bachelor in Medicine is of four years' duration, and comprises the following lectures:—

*Winter Courses.*—Anatomy and Physiology—Practical Anatomy with Dissections—Surgery—Chemistry—Practice of Medicine—Midwifery.

*Summer Courses.*—Botany—Materia Medica and Pharmacy—Institutes of Medicine—Medical Jurisprudence.

Hospital attendance on a Medico-Chirurgical Hospital during nine months, with three consecutive courses of clinical lectures. Also nine months' additional attendance on a recognised hospital, and Practical Midwifery.

Any of the courses may be attended at any recognised medi-

cal school, and three of them at Edinburgh University, provided the candidates have kept an *Annus Medicus* in the School of Physic.

The schools recognised are—1. The School of the Royal College of Surgeons in Ireland. 2. The Carmichael School. 3. The School of Stevens' Hospital. 4. The Ledwich School. 5. The Cecil-street School.

The fee for the *Licent ad Examinandum* is £5.

The fee for the degree of M.B. is £11.

#### Doctor in Medicine.

A doctor in medicine must be M.B. of at least three years' standing, and requires no other qualification.

Total fees for this degree, £13.

#### Master in Surgery.

This degree can only be obtained by Bachelors of Arts. The curriculum is the same as that for the Licentiate in Surgery, as given below.

Total amount of fees for the degree of Ch.M., £16.

#### Licentiate in Medicine.

Candidates for the licence in Medicine and Surgery must be matriculated in Medicine, and must have completed four years in medical studies, and must pass an examination in Arts, including Greek, Latin, English, and Mathematics, unless they be students in the Senior Freshman, or some higher class. The medical course necessary for a Licence in Medicine is the same as for the degree of M.B. A fee of £5 is charged on taking the Licence. Licentiates in Surgery of the Royal Colleges of Surgeons, on passing the Art Examination, will be admitted to examination for the Licence in Medicine. Such candidates will be exempted from examination in Anatomy and Surgery: Fee for the *Licent ad Examinandum* £5. Fee for the Licence in Medicine, £5.

#### Licentiate in Surgery.

Candidates must have kept one full year in Arts, and will be required to perform surgical operations on the dead subject. The curriculum extends over four years, and is as follows:—Two courses each of Anatomy and Physiology, and Theory and Practice of Surgery; three courses of Demonstrations and Dissections; and one course of each Practice of Medicine, Chemistry, Materia Medica, Midwifery, Laboratory Chemistry, Botany, and Medical Jurisprudence. Also attendance for three Sessions, each of nine months, on a recognised hospital. Of the course of lectures, which are of six months' duration, not more than three can be attended during any one session. Any of the above-named courses may be attended at any of the medical schools at Dublin, provided the candidate has kept an *Annus Medicus*. A fee of £5 is charged for the licence, and £5 for the *Licent*.

#### MEDICAL SCHOLARSHIPS.

Two medical scholarships are given annually, value 20*l.* per annum each, tenable for two years, the examinations for which are held each year in June, in the following subjects:—Anatomy, Physiology, Chemistry, Materia Medica, and Botany.

#### Medical School Exhibitions.

The professors of the University school give three exhibitions annually: two senior, value 15*l.* and 10*l.*, open to all students who have been three years attending the school. The subjects being—Practice of Medicine, Surgery, Pathology, and Forensic Medicine.

One junior, value 15*l.*—the time and subjects of examination being the same as those for the medical scholarship.

Expense of obtaining the degree of Bachelor in Medicine and Master in Surgery in the University of Dublin:—Lectures, 49*l.* 7*s.*; Hospitals, 28*l.* 7*s.*; Degree Fees, 32*l.* = 109*l.* 14*s.*; Private Tuition, say 20*l.*; Total 129*l.* 14*s.*

N.B.—As no degrees in Medicine or Surgery are conferred except upon graduates in Arts, the expense of the degree of Bachelor in Arts, amounting altogether to 83*l.* 4*s.*, should be added to the foregoing, making the total cost something over 200*l.*

The Board of Trinity College have recently passed orders:—

1. That three-fourths of the courses of lectures must be in all cases attended. 2. That the system of perpetual pupils be abolished. 3. That a daily roll be called by each Professor. 4. Students in Arts shall be entitled to attend one course in Botany, and to receive a certificate free of charge. 5. Candidates for degrees and licences in Surgery shall be required to attend one course only on Anatomy, for which he shall be charged three guineas. 6. The two courses delivered by the Professor of Surgery shall include practical instruction in Operative Surgery on the dead subject: and for each the

professor shall charge four guineas. 7. The professor shall charge three guineas for the winter lecture in Chemistry. 8. Laboratory instruction shall be substituted for the second course of chemistry, hitherto delivered, for which the Professor of Chemistry shall charge five guineas. 9. Students in Arts may attend the Professors of Surgery and Chemistry, and to receive certificates on payment of half the fees. 10. That after Shrovetide, 1868, all candidates in Medicine shall produce certificates in practical Midwifery, including at least six deliveries.

### THE QUEEN'S UNIVERSITY IN IRELAND. FACULTY OF MEDICINE.

#### DEGREE OF DOCTOR OF MEDICINE.

Each candidate for the degree is required—

1. To have passed in one of the Queen's Colleges the examination for Matriculation in Arts,\* and to have been Matriculated in Medicine. 2. To have attended in one of the Queen's Colleges, Lectures on one Continental language for six months, and on Natural Philosophy for six months. 3. To have attended, in some one of the Queen's Colleges, two other courses of the medical curriculum. For the remainder of the courses, certificates will be received from the Lecturers in Schools, recognised by the Senate. 4. To pass two University Examinations—The First University Examination and the Degree Examination.

The curriculum of Medical study extends over four years, and is divided into two periods of two years each.

The first period comprises attendance on Chemistry, Natural History, Anatomy and Physiology, Practical Anatomy, and Materia Medica. Practical Chemistry in a recognised Laboratory is also to be attended during the first period, and the practice during six months of a Medico-Chirurgical Hospital, containing at least sixty beds, together with the Clinical Lectures delivered therein.

The second period comprises attendance on Anatomy and Physiology, Practical Anatomy, Theory and Practice of Surgery, Midwifery and Diseases of Women and Children, Theory and Practice of Medicine, Medical Jurisprudence. During this period Students attend Practical Midwifery, and eighteen months' practice of a Medico-Chirurgical Hospital, containing at least sixty beds, and in which clinical instruction is delivered.

At least two of the above courses of Lectures must be attended in some one of the Queen's Colleges; the remainder may be taken at the option of the candidate, in any University, College, or School recognised by the Senate of the Queen's University.

The University Examinations are held twice in each year, in June and September.

Each candidate for examination in June must forward to the Secretary, before the 1st of June, notice of his intention to offer himself, along with his certificates; and each candidate for examination in September or October must forward similar notice, along with his certificates, before the 1st of September.

#### THE FIRST UNIVERSITY EXAMINATION IN MEDICINE.

The First Examination may be passed either in June or September.

Students may present themselves for this Examination at the termination of the first period of the Curriculum, or at any subsequent period.

Before being examined, each Candidate must produce evidence of having completed the course recommended for study during the first period.

#### HONOURS.

Competitors for Honours will be examined in all the subjects of the First Medical Examination, including Experimental Physics and Modern Languages.

#### DEGREE EXAMINATION IN MEDICINE.

Examinations for the M.D. will be held in June and September. The fee is £5.

Each candidate must produce—

1. A certificate from the Secretary of the Queen's University, that he has passed the previous examination, unless he presents himself for both examinations simultaneously.

2. From the Council of his College that he has passed a full examination for Matriculation in Arts, and has been admitted a Matriculated Student in the Faculty of Medicine,

3. That he has attended in the College lectures on one Modern Language, on Experimental Physics, and two other courses.

4. That he has completed all other prescribed courses.

The Degree Examination comprises the subjects recommended for study during the second period, along with Experimental Physics and one Modern Language, unless an Examination in these subjects has been already passed at the previous Medical Examination.

The examination for the Degree of M.Ch. comprises in addition an examination in Operative Surgery.

See advertisements of Queen's Colleges, Belfast, and Cork.

### ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE Council of the Royal College of Surgeons have recently adopted a new scheme of examination, which is to supersede the existing scheme in next December. The new method of examination is framed with the object of enabling the student to pass through his examinations *gradatim*, instead of being obliged to encounter the ordeal of the whole examination at one time. Thus, the divided examinations will be at once easier for the student, and a much more rational and perfect test than the old system.

The old system is, however, continued for the present, to enable students who have already commenced their curriculum to complete it as had been originally intended. All students joining the Profession, or who have passed their first examination, should proceed upon the new system, as it will be easier and much more instructive.

#### REGISTRATION OF PUPILS.

Every person, and without any examination, shall be registered as a pupil on payment of five guineas, which is allowed in his diploma fee as part payment.

Registered pupils can study in the museum on two days in each week, and read in the library every day from ten till one. They may also attend the Lectures on Comparative Anatomy, and obtain the certificate without payment. No student is admitted to the sessional or final examination for letters testimonial until he becomes a registered pupil, but he may register at any time previous.

#### CLASSICAL EXAMINATION.

Students are admitted to this examination at any period previous to the final examination for letters testimonial.

The following are the subjects for the Preliminary Examination:—The English Language, including Grammar and Composition. Arithmetic, including Vulgar and Decimal Fractions. Algebra, including Simple Equations. Geometry, first two books of Euclid. Latin and Greek, including Translation and Grammar. In Greek—The Gospel of St. John, the Menippus of Lucian, or the First Book of Xenophon's Anabasis. In Latin—The First and Second Books of the *Æneid* of Virgil, the Jugurthine War of Sallust, or the Third Book of Livy. These examinations are held quarterly, viz.:—On the third Wednesday in January, April, July, and October, in each year. Fee, ten shillings.

#### DIPLOMA IN MIDWIFERY.

Any Fellow or Licentiate shall be admitted to an examination upon the following documents:—

a. Certificates of one course of lectures on Midwifery and Diseases of Women and Children.

b. That he has attended a recognised lying-in hospital for six months; or a recognised dispensary for lying-in women and children, devoted to this branch of surgery alone.

c. That he has conducted thirty labour cases. Candidates for the Midwifery Diploma shall be examined on the organisation of the female; the growth and peculiarities of the fetus; the practice of Midwifery, and the diseases of women and children.

Licentiates of a college of physicians or graduates in medicine of a University, shall be examined in general and Descriptive Anatomy, Physiology, the Theory and Practice of Surgery, and Operative Surgery. Rejected candidates cannot present themselves until after six months.

The conduct of the examinations under the old scheme is the same as herein described, except that the examinations are two instead of three, and are held on the fourth Tuesday in January, April, July, and October.

\* The following are the subjects of Examination. Homer's *Iliad* Books I, II (omitting Catalogue of Ships), III; Lucian's *Dialogues* (Walker's edition); Xenophon's *Anabasis*, Books I, II, III; Virgil, *Æneid*, Books I, II, III; Sallust; Horace, *Satires*; Latin Prose Composition; English Prose Composition; English History; Modern Geography; Arithmetic; Algebra, to the end of Simple Equations; Euclid, Books I, II, III.

## CURRICULA.

The Junior Class shall produce certificates of three courses of Lectures on Anatomy and Physiology, three courses on Practical Anatomy, with dissections; two courses on Chemistry, one course on Materia Medica, one course on Botany, and one course on Forensic Medicine.

This class shall be examined in Anatomy, Physiology, and Materia Medica.

The Senior Class shall produce certificates of three courses on the Theory and Practice of Surgery, one course on the Practice of Medicine, and one course on Midwifery; also of attendance at a recognised hospital for three Winter and three Summer Sessions.

This class shall be examined in Surgery, Operative Surgery, the Practice of Medicine, and form of Prescription.

The examinations in Operative Surgery are conducted by the four surgical examiners. The questions are written upon cards deposited in a balloting-box, from which each candidate, as called up, draws his question, and performs the operations there indicated.

Any candidate rejected in Operative Surgery is not permitted to present himself for the senior *viva voce* examination.

The fee for this examination shall be fifteen guineas.

## FEES TO BE PAID BY CANDIDATES FOR LETTERS TESTIMONIAL ON THE OLD SYSTEM.

1st. The candidate pays ten shillings for his preliminary examination.

2nd. Five guineas as registered pupil of the College.

3rd. Five guineas for the Junior Class examination, which is not returned in case of rejection, but is allowed in the fee for his second examination.

4th. Fifteen guineas for the Senior Class examination—total, 26*l.* 15*s.*

5th. Every candidate rejected at the quarterly examinations shall be required to pay to the College the sum of two guineas on applying for re-examination.

6th. The Registrar receives 1*l.* 1*s.* on handing over the diploma.

*The New System, an outline of which appeared in our Number for August 23rd, and which comes in force in December, will be given fully in our next.*

## KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

## REGULATIONS RELATIVE TO THE LICENCE IN MEDICINE.

EXAMINATIONS are held on the second Tuesday in each month.

The name of every Candidate, together with his Schedule and the required documents must first be submitted to the College on the first Friday in each month, and no name can be received later than the Monday previous:

## REGULATIONS RESPECTING THE LICENCES IN MEDICINE AND MIDWIFERY.

Candidates who have not obtained some medical or surgical qualification must give proof of four years' study; and of having studied Anatomy and Physiology, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Botany, Medical Jurisprudence, Practice of Medicine, and Pathology, Surgery, Midwifery.

Of having attended a Medico-Chirurgical Hospital, with Clinical Lectures, for twenty-seven months.

Of six months' Practical Midwifery at a hospital, or other evidence of having attended Practical Midwifery.

Testimonials of character from two registered Physicians or Surgeons.

A Candidate who has already obtained a Medical or Surgical Qualification is required to fill up a Schedule; but he is only required to produce his Diploma or Certificate of Registration, and the Certificate of Practical Midwifery, and Testimonials as to character.

The examination is partly by written questions, partly *Viva Voce*, and partly Clinical, and divided into two parts:—

First Part.—Anatomy, Physiology, Botany, and Chemistry.

Second Part.—Materia Medica, Practice of Medicine, Medical Jurisprudence and Midwifery.

Candidates qualified as follows are required to undergo the second part only—viz., 1. Graduates in Medicine of a University. 2. Fellows, Members, or Licentiates, of the Colleges of

Physicians of London or Edinburgh, admitted upon examination. 3. Graduates or Licentiates in Surgery. 4. Candidates who, having completed the curriculum, shall have passed the previous examination of any of the Licensing Corporations in the United Kingdom.

Under this last regulation gentlemen who have passed the first portion of the examination for the Licence of the Royal College of Surgeons of Ireland or the Royal College of Surgeons of England are exempted from the first part of the examination.

Candidates who have been five years in practice are not required to undergo the written or clinical portion of the examination.

## REGULATIONS RELATIVE TO THE DIPLOMA IN MIDWIFERY.

Examinations for the Diploma in Midwifery are held on the day after those for the Licence in Medicine.

Candidates not being Licentiates will be admitted on the following qualifications:—The Degree or Licence in Medicine or Surgery, with a Certificate of six months' Lectures on Midwifery, with six months at a recognised lying-in Hospital, or of having attended Practical Midwifery for six months at a recognised lying-in Hospital, or other evidence of having attended Practical Midwifery

## FEES FOR LICENCE AND EXAMINATIONS.

The Fee for the Licence is £15 15*s.*

The Fee for the Midwifery Diploma is £3 3*s.*

The Fee for the Licence in Medicine and Diploma in Midwifery, if taken out within one month, £16.

Further information and blank schedules may be obtained by application personally, or by letter, to the Registrar, College of Physicians, Kildare street, Dublin.

## THE APOTHECARIES' HALL OF IRELAND.

THE Apothecaries' Company ought to be, but is not the body to teach Pharmacy and issue qualifications in it in Ireland.

A Pharmaceutical qualification is not required for any other purpose than keep open Apothecaries' shops. The practitioner is entitled to compound medicines for his own patients without it and, we believe, much of the public dispensing business of Ireland is transacted by persons who have no license from the Apothecaries' Hall. As a matter of fact, the Irish Apothecaries' Company may, as far as the control of Pharmacy in Ireland is concerned, be said to be *functus officio*, for a recent parliamentary return shows that although the Company gives its Licence for half-a-sovereign yet its gross annual earnings as a Licensing Body are barely 10*l.* a year, and it has been recently shown that in England 74 per cent. of the medical practitioners annually licensed take a Pharmaceutical qualification because it is a Pharmaceutical qualification; in Ireland only about 13 per cent. look for the License of the Hall, because it is not a Pharmaceutical License, but a mongrel medicine degree. As no more than twenty persons out of the whole number qualified in Ireland take the L.A.H., and as it is expected that the Pharmacy Act of England will shortly be extended to Ireland, and the examination in Pharmacy placed in the hands of the Pharmaceutical Society, we do not consider it necessary to occupy our space at length with the official regulations of the Apothecaries' Hall.

## MEDICAL SCHOOLS AND HOSPITALS.

THE Clinical Hospitals of Dublin are 10 in number, exclusive of the Cork street Fever Hospital, the Children's Hospital in Pitt street, and other special institutions. To some of these institutions Medical Schools are attached, others, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies, while others again are without any special connection with any school. While, however, such affiliation of a school and hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the Student is competent to attend any hospital and any school he wishes. The restriction which rendered it obligatory for Candidates for the Medical Degrees of the University of Dublin to attend Sir Patrick Dun's Hospital, was last year abolished, and perfect "free trade" thus established.

**THE SCHOOL OF PHYSIC T.C.D., AND SIR PATRICK DUN'S HOSPITAL.**—The Medical School is at Trinity College. Under the vigorous administration of the Medical Registrar, Professor Haughton, it has become one of the largest and most flourishing schools in Dublin. All Candidates for the Medical Degrees of the University *must* attend a certain proportion of their curriculum in it, but its certificates are valid everywhere.

The **ROYAL COLLEGE OF SURGEONS SCHOOL** is situated within the walls of the College, and is under the superintendence of the Council, who appoint the professors. The Introductory Address is given on the first Monday in November and immediately afterwards the Professor of Physiology commences his course with a series of twelve lectures on Comparative Anatomy—free to the public. The dissecting-rooms have been recently much enlarged. Prizes in Anatomy and Physiology, and Surgery, will be awarded at the end of the Winter Session. The Junior Surgical Society meets fortnightly in the school, and several prizes have been offered for the best essays read during the Session.

The **CITY OF DUBLIN HOSPITAL** has been hitherto more closely connected with the College School than any other hospital. It is situated in Upper Baggot street, about ten minutes' walk from the Royal College of Surgeons. The hospital contains 104 beds, and accommodates about 800 intern patients annually. There are special wards for ophthalmic and aural diseases (on which subjects a special course of lectures is delivered), and for diseases of children. A new wing has been lately opened for the reception of fever and other infectious diseases. The "Purser" Studentship of 20*l.* per annum (with apartments) is obtainable by competitive examination by all students; numerous prizes and medals are given, and special certificates are granted.

The **CATHOLIC UNIVERSITY SCHOOL** is situated in Cecilia street, about ten minutes' walk from the University itself in St. Stephen's Green.

The Hospitals most closely connected with this School are St. Vincent's, in St. Stephen's Green; the Mater Misericordiarum Hospital, in Eccles street; and Jervis street Hospital.

**ST. VINCENT'S HOSPITAL** was established in 1834 by the Sisters of Charity, some of whom had studied the system of the Parisian hospitals, after which it was modelled. The ward for "*Enfants Malades*" is an interesting feature. The hospital has over a hundred beds constantly full, and each sister has charge of about twelve patients. In connection with it a Convalescent Home was established two years since at Stillorgan. The clinical instruction in medicine and surgery is given by Dr. Quinlan, Dr. Mapother, Dr. O'Leary, and Dr. Cryan. Senior and Junior Prizes in clinical medicine or surgery are awarded at the end of the Winter Session.

A respectable lodging-house in Lower Leeson street (within a minutes' walk of the hospital) provides lodgings for students, at from 5*s.* per week and upwards. Maintenance varies, according to the habits of the student, from 1*l.* to 30*s.* per week.

The Introductory Lecture will be delivered by Dr. O'Leary on Monday, November 6th, 10.30 a.m.

The **MATER MISERICORDIÆ HOSPITAL** is the largest of the Dublin hospitals, and is intended to be much extended. It is situated on the northern outskirts of the town, and, therefore, a considerable distance from any of the Medical Schools. The portion now completed contains 180 beds, 50 of which are devoted to fever and other contagious diseases.

It is under the special care of Cardinal Cullen and the Trustees of the Catholic University.

There are three resident pupils appointed every six months. Good lodgings can be had very cheap close to the hospital. Prizes to the value of 30*l.* are awarded at the end of the Winter Session, for the best reports on the cases under treatment

in the hospital. The Introductory Lecture will be delivered by Dr. Nixon, Assistant Physician.

**JERVIS STREET HOSPITAL** is one of the oldest established charitable institutions in Dublin, having been founded in 1721. It is situated in the neighbourhood of the Carmichael and Catholic University Schools, and in a part of the city not otherwise provided with hospital relief, and which, from its commercial character supplies the hospital with an abundance of surgical cases. The hospital being found inadequate to the demands upon it, is about to be rebuilt. There will be no Introductory Lecture.

The **LEDWICH SCHOOL** was founded in 1810, by the well-known Dr. Kirby, and since then has fully sustained its prestige under the management of the Messrs. Ledwich and Mason, after the former of whom it is named. It is situated in Peter street, not five minutes' walk from the College of Surgeons, the Meath, and Mercer's Hospitals, and in the same street with the Adelaide Hospital and the Anglesey branch of the Coombe Lying-in-Hospital, and ten minutes' from the Catholic University School, the School of Physic, and the City of Dublin Hospital.

**MERCER'S HOSPITAL** was founded on the bequest of Mrs. Mary Mercer. It is one of the oldest hospitals in Dublin, and receives a great number of accident cases. It is situated in Stephen's street, close to the College of Surgeons, Ledwich School, and Adelaide Hospital.

The **CARMICHAEL SCHOOL** is situated in North Brunswick street.

The various lectures are now delivered, and the dissections carried on in the new building, which the munificence of the late Surgeon Carmichael has given to the proprietors. As the building was designed with special reference to the requirements of a large medical class, every convenience is afforded to the student in the prosecution of his studies.

The connection of this School with the Mater Misericordiarum, Meath, and Jervis street Hospitals, through its teachers, ensures equal opportunities to the pupils of becoming thoroughly acquainted with the more immediately practical part of their profession.

Arrangements have now been completed for rendering more available the Carmichael premium bequest, which will henceforth enable the proprietors to distribute prizes to the amount of 60*l.* yearly; and the Scholarship, value 15*l.* yearly, which the friends of the late Dr. Mayne have founded in his name, will be allotted at the termination of the Winter Session.

There is no Introductory at this school.

**DR. STEEVEN'S HOSPITAL AND SCHOOL** are situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, and, therefore, occupy a position of their own, far removed from the other medical institutions.

Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane.

There is accommodation for residence of seven surgical and four medical residents; besides whom the Resident-Surgeon receives house pupils. The fees payable for the privilege of residence are 21 guineas, winter; 15 guineas, summer six months; including hospital ticket; students have apartments, coal, gas, and furniture.

Accommodation outside the hospital, in the neighbourhood, is arranged by the hospital authorities.

#### PRIZES.

3 Cusack Medical and Exhibition, of 8*l.*, 5*l.*, 3*l.*; 2 Midwifery Assistants, 30*l.* each; 1 Medical Clinical Prize, 10*l.* 10*s.*; 1 Surgical Prize, 10*l.* 10*s.*

The session opens with the distribution of prizes in the first week in November.

**THE MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.**—This hospital is situated about a quarter of an hour's walk from the University, and within a few minutes of the College

of Surgeons and the Ledwich Schools of Medicine; affords every facility for the treatment and study of disease. Its salubrious position and long-established character call for constant admission to its accident, chronic, fever, surgical, and children's wards, which are thus constantly occupied with cases illustrative of medicine and surgery.

Four prizes will be given at the termination of the Winter Course to the best answerers in their respective classes.

As we have said, certain hospitals have no special affinity with any College or School. Of these are the Meath and Adelaide Hospitals.

The ADELAIDE HOSPITAL is in Peter street, next door to the Ledwich School, and within a few minutes' walk of the College of Surgeons and the Universities. From the 1st of October the physicians and surgeons will visit the wards, and give instructions at the bedside, at the advertised hours, and the course of clinical lectures will be commenced in the beginning of November.

The Special Hospitals of Dublin are the Westmoreland Lock Hospital, Cork street Fever Hospital, and St. Mark's Ophthalmic Hospital.

The LOCK HOSPITAL is supported by Government for the treatment of venereal diseases, and as such is one of the most valuable special hospitals in Dublin. Mr. McDowell and Professor Morgan are its surgeons, and especially for military surgeons the practice of the hospital is very valuable.

#### LYING-IN HOSPITALS.

ROTUNDO HOSPITAL.—This well-known institution is the largest and oldest maternity hospital in the United Kingdom, and the repute in which it is held attracts students from all parts of the world. It accommodates an average of 1,700 intern patients, including those admitted to the chronic wards labouring under the various forms of uterine complaints, and is under the care of the Master, who is elected every seven years, and two assistants, who hold these appointments for three years. The mastership is at present held by Dr. Johnston, and the assistants are Dr. Alexander Taylor and Dr. Cranny. There is, in addition, an external maternity department, where patients, procuring a ticket properly signed, can be attended at their homes; also, a dispensary is held every morning for diseases of women and children. Clinical instruction is given each morning both in the labour as well as in the chronic wards, and two courses of lectures are delivered in the year, which are recognised by all the licensing bodies.

A student entering for the practice of the hospital pays a fee of 10*l.* 10*s.* for six months. During that time he is required to attend at least thirty cases, either within the walls of the hospital or at the residence of patients who may apply for assistance. For this course of study, on examination, a diploma is given, which is received as a qualification in midwifery in the public services.

A limited number of students are admitted to reside in the hospital, for which they pay a fee of twenty guineas for six months.

COOMBE HOSPITAL.—This hospital was founded in 1826, but it was not till 1867 that it was incorporated by Royal Charter, which enables its medical officers to issue diplomas qualifying the holders to practise midwifery. By a clause in the Charter the diplomas issued antecedent to its date have been made with equal force and value with those issued subsequent thereto. This hospital divides with the Rotundo almost the entire of the obstetric hospital practice of Dublin. It is situated in the centre of a district densely populated by the lower orders, and thus affords the amplest opportunities for practice. It accommodates about 600 labour cases within its walls, while those attended as externs amount to nearly double that number. Moreover, the chronic ward for the reception of cases of the diseases of females gives ad-

mission to about eighty patients annually. Its wards are in the charge of Dr. Ringland and Dr. Sawyer, as masters, and Dr. A. H. Ringland as assistant master, whilst the chronic ward for the diseases of females is under the charge of Dr. Kidd, the obstetric surgeon of the institution. The fee for attendance is 4*l.* 4*s.* for six months as extern, and 10*l.* 10*s.* as intern pupil. During that period the student attends on a given night in each week, or oftener, if circumstances permit, and takes charge in his turn of any cases that may be admitted to the labour wards, or may call for his assistance outside. In difficult cases he has the superintendence of the resident medical officer, and of the masters when necessary. An annual examination is held in May and November, at which prizes of considerable amount are awarded, and certificates of good answering granted. Two paid resident pupil midwifery assistantships are obtainable annually by competitive examination, for which all pupils who have obtained their midwifery diploma are eligible.

THE ROYAL COLLEGE OF SCIENCE, established at the Museum of Irish Industry, in St. Stephen's Green, is a branch of the Science and Art Establishment at South Kensington. A complete Staff of Professors is connected with the institution, and courses of lectures are delivered on all Scientific Departments to which the admission charge is nominal.

#### RELATIVE COST OF MEDICAL EDUCATION IN IRELAND.

| UNIVERSITY OF DUBLIN, M.B. AND M.Ch.                          |     | £    | s. | d. |
|---|-----|------|----|----|
| I. Lectures   | ... | 49   | 12 | 0  |
| II. Hospitals   | ... | 33   | 12 | 0  |

|   |     | 115  | 4  | 0  |
| Expense of Degree in Arts                                     | ... | 83   | 4  | 0  |
| Total   |     | £198 | 8  | 0  |
| QUEEN'S UNIVERSITY M.D. AND M.Ch.                             |     |      |    |    |
| If two years' Lectures and Hospital be taken in Dublin, about | ... | £67  | 0  | 0  |
| COLLEGES OF SURGEONS AND PHYSICIANS.                          |     |      |    |    |
| About   | ... | £140 | 0  | 0  |

On these terms a reduction may be made by cash payments to Hospital and College at the commencement of study.

#### INTRODUCTORIES IN ENGLAND AND IRELAND.

LIST of Introductory Lectures to be delivered at the opening of the Session 1871-2:—

- St. Bartholomew's Hospital—No Introductory this Session.
- Charing Cross Hospital—Dr. Green—October 2nd, 8 P.M.
- St. George's Hospital—Dr. John Clarke—October 2nd, 2 P.M.
- Guy's Hospital—Dr. Oldham—October 2nd, 2 P.M.
- King's College—Dr. Rutherford—October 2nd, 4 P.M.
- London Hospital—Dr. Little—October 2nd, 3 P.M.
- St. Mary's Hospital—Dr. A. Meadows—October 2nd, 3 P.M.
- Middlesex Hospital—Dr. John Murray—October 2nd, 3 P.M.
- St. Thomas's Hospital—Mr. Le Gros Clark—October 2nd, 2 P.M.
- University College—Dr. Chariton Bastian—October 2nd, 3 P.M.
- Westminster Hospital—Dr. Basham—October 2nd, 3 P.M.
- Bristol Medical School—October 2nd.
- Birmingham (Queen's College)—Dr. Russell—October 3rd, 3 P.M.
- Leeds School of Medicine—Dr. Clifford Allbutt—October 2nd, 12 noon.
- Liverpool Royal Infirmary School of Medicine—Dr. W. Carter—October 2nd, 3 P.M.
- Manchester Royal School of Medicine—Mr. R. T. Hunt—October 2nd, 12 noon.
- Newcastle College of Medicine—Dr. Philipson—October 2nd, 2 P.M.
- Sheffield School of Medicine—Mr. A. Allen—October 2nd.
- Aberdeen University—November 1st.
- Edinburgh University—Sir A. Grant, Bart., LL.D.—November 1st.
- Edinburgh School of Medicine—Mr. Annandale—November 1st, 11 A.M.
- Glasgow University—Dr. Dickson—October 31st.
- Glasgow Anderson's University—October 31st.

#### DUBLIN.

The Dublin Medical Schools open their Dissecting-rooms on October 2nd, but lectures do not begin until the end of

ESTABLISHED A.D. 1800.

;BRANCH—26 COOK STREET, CORK.

CATHOLIC UNIVERSITY SCHOOL OF MEDICINE,  
CECILIA STREET, DUBLIN.

THE WINTER SESSION, 1871-72, will commence with Dissections on MONDAY, 2nd October.

The Lectures will be commenced on FRIDAY, November the 3rd, at Three o'clock p.m., by an INAUGURAL ADDRESS from the Dean of Faculty, Dr. CRYAN.

The several Courses will be as follows:—

Anatomy and Physiology—Dr. Hayden, Dr. Cryan.  
Anatomical Demonstrations—The Professors of Anatomy and Physiology.

Chemistry—Dr. Sullivan.

Theory and Practice of Surgery—Mr. Tyrrell.

Theory and Practice of Medicine—Dr. Lyons.

Theory and Practice of Midwifery—Dr. Byrne.

Practical Chemistry—Dr. Sullivan.

Materia Medica—Dr. Quinlan.

Medical Jurisprudence—Dr. MacSwiney.

Pathology—Dr. Lyons.

Botany—Dr. Sigerson.

Logic—Dr. Dunne.

Natural Philosophy—Mr. Hennessy, F.R.S.

Dissections under the superintendence of the Professors of Anatomy and the Demonstrators....

Dr. Hayes.  
Dr. Fennelly.  
Dr. Nixon.  
Dr. Ward.  
Dr. Coppinger.

The Lectures delivered in this School are fully recognised and received by the Universities and all other licensing bodies in the United Kingdom. The School is, therefore, strictly on an equality, as regards privileges, with any other School of Medicine in Great Britain or Ireland.

Special accommodation has been provided by the University for the residence of Medical Students, under the direction of a resident Dean. Application to be made to the Very Rev. Dr. O'Loughlin, or the Very Rev. Dr. McDevitt, 85 and 86 Stephen's Green South.

A Connolly Exhibition (value £20) will be offered for competition at the termination of the Winter Session, in the combined subjects of Physiology, Physiological Anatomy, Chemistry, and Botany; also a Gold Medal of the value of £7, in Surgery, Practice of Medicine, and Midwifery (including female and infantile diseases). The usual class prizes will likewise be given.

The Summer Session, 1872, comprising Operations in Practical Chemistry, and Lectures on Materia Medica, Medical Jurisprudence, Pathology, Botany, Natural Philosophy, and Logic, will commence on the 15th April, and terminate on the 15th July, when class Prizes will be awarded in each subject, and a University Exhibition (value £20) in Practical Chemistry, Materia Medica, and Medical Jurisprudence combined.

For particulars, apply at the School, Cecilia street.

PATRICK J. HAYES, Medical Registrar.

THE ADELAIDE HOSPITAL, PETER STREET,  
DUBLIN.

Physicians—Henry H. Head, M.D., M.R.I.A., Fellow of the College of Physicians, James Little, M.D., M.R.I.A., Fellow of the College of Physicians, Lecturer on the Practice of Medicine in the Ledwich School of Medicine.

Surgeons—Albert J. Walsh, M.D., President Royal College of Surgeons, John K. Barton, M.D., Fellow Royal College of Surgeons, Lecturer on Surgery in the Ledwich School of Medicine, Benjamin Wills Richardson, Fellow and Member of the Court of Examiners, Royal College of Surgeons.

Obstetric Physician—Lombe Atthill, M.D., Fellow and Examiner in Midwifery, College of Physicians.

Ophthalmic Surgeon—H. Rosborough Swanzy, M.B., L.R.C.S.I., lately Assistant at Professor von Graefe's Ophthalmic Hospital, Berlin.

Assistant-Physician—Walter G. Smith, M.D., Fellow and Censor College of Physicians, Senior Demonstrator in the University School.

Assistant-Surgeon—Montgomery A. Ward, M.B., M.Ch., L.R.C.S.I., Demonstrator of Anatomy, Ledwich School of Medicine, Ex-Medical Scholar, T.C.D.

The central position of this Hospital renders it peculiarly convenient to gentlemen attending Lectures at the University, College of Surgeons, or Ledwich School. The arrangements for Clinical Teaching have been made as complete as possible, and are such as not to interfere with attendance at the Medical Schools. There are Fever Wards apart from the Hospital, and two Wards for Infants and Children. Special hours are devoted to Clinical Instruction in the Diseases peculiar to Women, the Diseases of the Eye, and Cutaneous Diseases, and Students are individually instructed in the Use of the Stethoscope, Ophthalmoscope, Laryngoscope, and Microscope. Two Resident Pupils are selected half-yearly. Prize Examinations are held at the termination of the Session.

Further particulars can be obtained from Dr. Atthill, 11 Upper Merion street, or any other Member of the Medical Staff.

## PRIVATE RETREAT

FOR

THE UPPER AND MIDDLE CLASSES  
OF BOTH SEXES, MENTALLY AFFLICTED,

TUE BROOK VILLA,  
NEAR LIVERPOOL.

Further information may be obtained on application to Dr. H. OWEN.

### CLINICAL LECTURES

ON THE

### DISEASES PECULIAR TO WOMEN.

By LOMBE ATTHILL, M.D. Dub.,

Fellow and Examiner in Midwifery King and Queen's College of Physicians; Obstetric Physician to the Adelaide Hospital, Dublin.

#### LECTURE XIII.

*Displacement of the Uterus. — Retro-flexion — Causes of, Symptoms of, Treatment by Hodge's Pessary. — Value of Local Blood-letting. — Ante-flexion. — Protrapsus Uteri.*

The healthy unimpregnated uterus is an organ of great mobility. Its connection with the pelvic walls by means of the broad ligaments, which are merely folds of the peritoneum, is so very lax that it can without difficulty be inclined either anteriorly or posteriorly; they no doubt oppose a certain amount of resistance to its lateral motions, but very little to its movements in other directions, while the round ligaments which do materially aid in supporting it, are yet incapable of offering any effectual opposition to either the descent, muchless to inclinations of the womb in an anterior or posterior direction, so should the organ in consequence of its being in an abnormal condition become liable to displacement. In young women who have not borne children, the muscular structure of the vagina, forming as it does a firm tube into which the cervix uteri is inserted, aids materially in supporting the womb; but in women in whom that canal has become relaxed from the effects of frequent parturition, or of local or constitutional disease, the support afforded by it is in a great measure wanting, and the organ may sink directly down, a displacement the tendency to which becomes greatly aggravated should the womb as is frequently the case, be from any cause enlarged and heavy. But common as prolapse

of the uterus is, the other displacements to which the organ is liable are still more so. Hardly a day passes in which we do not meet with examples among the extern patients of flexions of the womb either backwards or forwards. I shall call your attention to these first and afterwards return to the consideration of prolapse.

The womb then may be bent on itself either in a posterior or anterior direction, and to these flexions the terms retroflexion and antelexion are especially applied. Now it is of importance that you should clearly understand what is meant by these terms. Some writers, and among them the late Sir J. Simpson used the words retroversion and retroflexion as synonymous, but in reality they indicate two very different affections, for retroversion signifies a turning back of the entire uterus, and is applicable to that change of position to which the gravid womb is liable, in which the fundus lies in the sacral hollow, the os being forced up behind the pube, a condition very rarely seen unconnected with pregnancy; while by retroversion on the other hand is to be understood a bending back of the fundus alone, the os remaining very nearly in its natural position. In cases of antelexion the fundus is in like manner bent forwards.

Retroflexion which is by far the most common displacement to which the uterus is liable may be met with at nearly every period of life from puberty onwards. It is however rare in youth and in advanced age, the great majority of cases occurring during that period of life in which the uterine system is in the state of its greatest activity, namely, between the ages of twenty and forty years. It is besides an affection, the existence of which is more liable to be overlooked than any other form of uterine disease, this being due rather to the fact that the symptoms to which it gives rise have often but little apparent reference to the uterus, than to any difficulty in detecting it when once our suspicions are aroused.

When we consider the position of the uterus in the pelvis with the bladder, an organ capable of such immense distension placed in its immediate front, and constantly exercising a pressure backwards, and when we remember that many women from mere habit or from motives of

delicacy oftentimes pass many hours without emptying that viscus, we can readily understand the frequency of this displacement as compared with any other to which the uterus is liable. But though the distended bladder may thus be the agent in directing the uterus backwards it is but a secondary cause, for the uterus itself must be in an abnormal condition otherwise it would regain its proper position whenever the bladder became flaccid. Retroflexion is however in my opinion generally produced gradually, and is the result of affections which increase the bulk and weight of the uterus, and more especially of its fundus. It is not however necessary that the increase should be confined to the fundus, though if that be the case the danger of retroflexion occurring is much increased, for if the bulk of the entire uterus be augmented this may still take place, because not only is there a force acting from before, directing the fundus downwards and backwards, but also because there is no resistance from behind to counteract that tendency.

We however frequently meet with cases in which, while retroflexion obviously exists, the uterus certainly is not enlarged or increased in weight, but this is capable of explanation if we bear in mind that, when the uterus is bent on itself at an angle, the circulation must be seriously interfered with. Congestion doubtless at first occurs, but subsequently, if the case be neglected, atrophy of the organ may result. In time the original cause of the affection may cease to exist, but the uterus does not necessarily on that account regain its normal position, for not only may the fundus be bound down by adhesions formed on its peritoneal surface, but also a process of absorption and consequent thinning may take place at the point of flexion, especially on the lower or concave surface, so that even when no adhesions exist permanent restoration of the uterus to its normal position is impossible, and this fact enables us to understand the unsatisfactory results which often follow treatment adopted for the cure of cases of old standing.

The causes producing the condition likely to result in retroflexion may be reduced to three classes—namely—

1st. Congestion frequently terminating in chronic inflammation of the uterus, and hypertrophy of that organ.

2nd. Subinvolution of the uterus after labour or abortion.

3rd. Tumours of the uterus.

But in addition to those in which we can trace the flexion to the existence of one of the conditions here enumerated, we occasionally meet with cases the origin of which is so obscure as to prevent our being able to decide as to the mode of their occurrence. Dr. Barnes in a recently published lecture on this subject suggests that in many, the flexion may be congenital, an opinion which I think probably is correct.

I believe congestion of the uterus to be a common cause of retroflexion, and one frequently overlooked. It is met with in two very different classes of females—namely, those who lead a very active life; and again, in those of weakly constitution and sedentary habits such as needlewomen and teachers. Thus young women of active habits who from necessity or for pleasure walk, ride, or garden much, or who follow employments, or amusements, necessitating much standing, will sometimes continue to pursue these duties or amusements during the catamenial period, the result is that the organ remains congested for an undue length of time, and a condition favourable to chronic inflammation is produced. The following case illustrates this form of the disease:—

M. F., æt. twenty-five, unmarried, has always lived a very active life, and till within a comparatively recent period enjoyed excellent health. About three years ago having been compelled to undertake the superintendence of a large farm, she underwent great fatigue, generally spending from eight to twelve hours each day in the open air, either on foot or on horseback, and never relaxing her exertions even during her menstrual periods. She at first

suffered from a sense of fullness and weight in the lower part of the abdomen, but to these symptoms she paid no attention. At about the end of a year she for the first time perceived a new train of symptoms. She now experienced difficulty in passing water, and was obliged to strain in doing so. After a little time her sufferings were further increased by a difficulty experienced in defæcation. The bowels were not actually constipated but their action caused great pain, and the fæces when passed were as small as those of a little child. The catamenia appeared regularly but in diminished quantities. I felt in this case as I always do when the patient is unmarried, great reluctance to make a vaginal examination, but her sufferings were so great and treatment directed to other organs had so entirely failed to afford relief I deemed it absolutely necessary to ascertain the condition of the uterus, and on examining I discovered that organ to be much enlarged, tender to the touch, and completely retroflected, its fundus occupying the hollow of the sacrum and pressing against the rectum, this explained one of her symptoms—namely, the difficulty experienced in defæcation, the irritation of the bladder being evidently reflex. With the view of retaining the uterus in its normal position I introduced a Hodge's pessary. The fundus was raised without difficulty, but the pessary first used proved to be too large, and caused so much pain that, after the lapse of a few hours, it had to be removed. On a subsequent day, however, I introduced a smaller one. This answered admirably, and she experienced such relief that she was able to return home, and has since followed her ordinary occupations. In this case the retroflected uterus was in a state of chronic inflammation, and to this condition her greatest sufferings were due. In the following case, however no inflammation was present. The uterus was simply congested, and a very different train of symptoms manifested themselves.

A schoolmistress, æt. twenty-one, had suffered for more than a year from occasional attacks of vomiting, which for the last three months had become incessant. She had been treated in various ways, but without benefit, and at the time I saw her in consultation with my colleague Dr. Little, under whose care she had been admitted, rejected everything she swallowed. She even vomited lime water and milk, and this though only one spoonful had been given at a time and at regular intervals, no other food of any kind being allowed. In like manner she had been fed on beef-tea exclusively, a spoonful only being given at intervals of fifteen minutes. The food thus taken would be retained for a time, till some ounces had been swallowed, then the whole would be rejected. Nevertheless she had not become actually emaciated, and she only complained of debility, and pain in the pit of the stomach and in the back. The catamenia appeared at regular intervals, but in much smaller quantities than formerly. On examining the abdomen tenderness on pressure was detected over the left ovary, and to that spot four leeches were applied. The effect was marked. That afternoon the stomach retained some beef-tea, that being the first food retained for several weeks. The vomiting, however, did not entirely cease, it still occurred once or twice a day, nearly always in the morning. Being now satisfied that the vomiting depended on some reflex irritation, we decided on making a vaginal examination, and I was somewhat surprised to find the uterus completely retroflected. The fundus was enlarged and occupied the hollow of the sacrum. It was easily raised to its normal position, and to retain it there I introduced a Hodge's pessary of small size. This was from the very first borne without inconvenience, and from the time it was introduced the vomiting entirely ceased. The catamenia subsequently appeared in much larger quantities. I removed the pessary after it had been worn for three months. Since then there has been no return of her distressing symptoms, and I understand that she is now married.

Both these patients were unmarried women, in both congestion of the uterus occurred, which in one had

reached, in the other was slowly assuming, the form of chronic inflammation, when this happens the patients sufferings are always greatly aggravated. She will tell you that in addition to pain in the back, she suffers from severe lancing pains over the pubes, in the groin, and shooting down along the course of the crural nerve. Change of posture, or any motion, aggravates this pain, which sometimes becomes so severe as to render walking a matter of great difficulty.

Dr. Graily Hewitt has recently described this condition, and applied to it the term of "uterine lameness." Often too in these cases the bladder sympathises and a constant desire to micturate wears out the patient; touching the fundus of uterus causes pain sometimes of a very severe character. Sexual intercourse therefore becomes so painful and distressing as to be actually impossible. It is this form of the affection which most imperatively calls for our interference, for it gives rise to great distress and often lays the seeds of unhappiness in married life.

The following case exemplifies the distress which exists in cases of retroflexion when aggravated by the occurrence of chronic inflammation of the uterus. S. B., *æt.* twenty-eight, had been married for eight years. Not long after marriage, when in the fourth month of pregnancy, she fell down stairs and was much hurt. As the result of this accident she aborted. For a year following she continued in a miserable state, the pain in her back and in the region of the uterus being so severe that she was seldom able to leave her bed. The catamenia were scanty and irregular. She was at length induced to go to Edinburgh, and placed herself under the care of Sir J. Simpson. He incised the cervix uteri, and introduced a stem pessary. Severe inflammation followed and the instrument had to be removed. From this attack she recovered, and returned home feeling somewhat better, but soon relapsed into a condition even worse than before. She now experienced a distressing feeling of weight in the neighbourhood of the rectum; this was greatly increased and accompanied by severe pains at the menstrual periods, which recurred regularly, the discharge however being very scanty and lasting only a few hours. At length she became a confirmed invalid. Walking caused such suffering that she dared not attempt even to cross the room. The uterus was completely retroflected, the fundus which occupied the hollow of the sacrum being very tender to the touch. The os was gaping and freely admitted the tip of the finger, and a copious discharge of semi-purulent fluid exuded from it. I leached the cervix on three occasions, and when the tenderness of fundus was lessened, introduced one of Hodge's pessaries, which she wore without inconvenience. Her condition has since steadily improved. Menstruation now lasts for two or three days, and she is able to perform her usual household duties. She still continues to wear the pessary. In this case as well as in the foregoing one, menstruation though not entirely suppressed had become very scanty. The reverse will be found to be nearly invariably present when the flexion depends on other causes.

You doubtless remember my having pointed out the fact, that not infrequently after labour or abortion, the uterus from various causes fails to regain its natural size, and remains unduly enlarged; to this condition the term "subinvolution" is applied. When this is the case the organ is peculiarly liable to retroflexion, for not only is its fundus unduly heavy but the muscular fibres also are relaxed, consequently the natural rigidity of the organ is in a great degree wanting. When retroflexion occurs as a sequence of subinvolution, it gives rise to very grave symptoms, the most prominent of which nearly invariably is menorrhagia. Indeed it is frequently for the relief of this that we are most commonly consulted. We have recently had in our wards a good example of this. The woman was admitted suffering from menorrhagia, and from severe left-side pain; she stated that three months after the date of her last confine-

ment menstruation came on very profusely and lasted for six weeks, and that on each subsequent period the loss had been considerable. On examination the uterus was found to be retroflected, the whole of the organ being also enlarged; but it was *not tender* to the touch, nor was sexual intercourse painful, and the introduction of the uterine sound caused no distress. You see at once how strongly this case contrasts with the ones previously detailed. Here is another, the particulars of which I have recorded in my note-book. A lady gave birth after a very difficult labour to a still-born child, about five months previous to my seeing her. Considerable hæmorrhage followed delivery, and her convalescence had been very slow. Subsequently she suffered from profuse menstruation, had gone to the seaside and been treated by the administration of tonics, but without effect. On examining her I found the uterus to be completely retroflected and much enlarged. The case was clearly one of subinvolution of the uterus and subsequent retroflexion. This lady did not suffer any pain. She complained of the debility consequent on the menorrhagia and of nothing else.

There is no doubt but that the presence of a tumour in the cavity of the uterus may predispose to its flexion, or again, by bulging out one wall it may simulate a flexion, although in point of fact the axis of the uterus remains unchanged. This was so in the patient whose case is illustrated by the diagram in Plate II, Lecture vi. The uterus appeared to be antelected, but in reality the anterior wall had merely yielded to the pressure exerted by the polypus as it increased in size. In like manner fibrous tumours, if situated within the cavity, may bulge out the walls of the uterus, or if embedded in them or situated on the peritoneal surface, may possibly by their weight draw the fundus of the uterus downwards. Care therefore is needed to discriminate between a retro- or antelected uterus and an extra-uterine fibroid projecting from its surface, or an intra-mural or intra-uterine tumour bulging the wall outwards. It is only by means of the uterine sound that you can clear up this point.

From the details of the cases to which I have called your attention, you will see that the symptoms they present vary much, and are very vague; still, as I shall presently notice, they present some well-marked points, common to at least all the cases falling under one of the heads into which I have classed them.

If you refer to most of the works on diseases of women, you will find the symptoms of retroflexion of the uterus stated to be "a sense of weight" in the pelvis, "pain in the back," or "shooting down the thighs," &c., symptoms which are common to nearly every form of uterine disease, and, therefore, worthless as a diagnostic mark; while, with respect to the menstrual function, no attempt is made to apply to it any definite rule. Thus Sir J. Simpson, in the first volume of his "Obstetric Works," says that he has found the "catamenial discharge to be most oppositely affected, occasionally in the way of menorrhagia, sometimes of dysmenorrhœa." Again, Dr. Churchill says, "Menstruation may be profuse or painful, or both." I cannot but think that this apparent contradiction in the description of symptoms is due mainly to the want of careful discrimination between two classes of cases, depending on totally different conditions of the same organ. Doubtless there is not any one symptom on which we can rely as indicating the existence of retroflexion of the uterus, and I do not remember in my own practice a single case in which, prior to my making a vaginal examination, I had sufficient grounds for concluding that this displacement existed. Thus in the first of the cases which I have detailed, the most prominent symptoms were irritation of the bladder and difficulty in defecation; in the fourth they were pains over the ovary and total inability to walk; while in the second regurgitant vomiting alone was complained of. Another case presented an example of uterine lameness, and in her the uterus was so tender to the touch, that sexual intercourse was impossible. In all these cases, however, differing as they do in

other respects, the menstrual function was similarly affected, being in all much diminished in quantity. In two other cases, on the contrary, menorrhagia was the sole symptom which attracted the patient's attention. And, again, in a case recently under observation, although menstruation was profuse and weakening, the prominent symptom was paroxysms of intense pain. But though the result produced—namely, retroflexion—was in all these cases alike, the causes giving rise to that result were different. Thus, in those in which menstruation was diminished, the retroflexion was the result of congestion terminating in chronic inflammation, and slowly produced hypertrophy. In the others, where menorrhagia existed, it followed on subinvolution, so the catamenial discharge will be diminished or increased in respective cases.

I have already noticed the occurrence of vomiting as having been the prominent symptom in one case; this of course, was due to reflex irritation; but the stomach is not the only organ liable to sympathise with the uterus when it is retroflected; the mammae may be affected. Thus I recently was consulted by a married lady, mainly for the purpose of deciding whether she was pregnant or not. She stated that four years previously she had given birth to a living child, and that subsequently she had several times become pregnant, but on each occasion had miscarried at the end of the third month. She supposed that she was now again pregnant, because she suffered from incessant nausea, while at the same time her breasts had become enlarged, painful, and distended with milk; but still she was in doubt, because the catamenia appeared not only regularly, but in increased quantity. I speedily satisfied myself that she was not pregnant. The uterus was retroflected. It was manifestly a case of subinvolution, terminating in retroflexion. In this case a pessary was at first badly borne, though finally one was introduced, which answered admirably.

From the consideration of the foregoing cases, I think we may fairly draw the following conclusions:—

1st. That retroflexion of the uterus is a common affection, and that it is met with both in married and unmarried females.

2nd. That it is generally a secondary, not a primary affection.

3rd. That when it is due to congestion, or chronic inflammation of the uterus, terminating in hypertrophy, the catamenia are diminished in quantity, and frequently painful.

4th. But that when retroflexion is the result of subinvolution of the uterus, following labour or abortion, the catamenial discharge is increased in quantity, sometimes even to an alarming degree.

5th. That in addition to the symptoms common to all forms of uterine disease—namely, pain in the back, sense of weight, &c.—we have not unfrequently, where the uterus is retroflected, reflex irritation of the bladder, stomach, and breasts, occurring as to frequency in the order given, and also constipation of the bowels.

It is seldom that much difficulty is experienced in recognising a retroflected uterus; you feel a tumour in the recto-vaginal *cul de sac*, which you can in most cases raise by making pressure on it with the finger; and in doing so you can generally satisfy yourself that it is the fundus of the uterus, the cervix of which lies in its natural position; but the use of the sound will decide the question; for if the uterus be retroflected, the instrument will pass with its concavity towards the sacrum; and when introduced you can in most cases, by giving the handle of the instrument a half turn, raise the retroflected fundus to its normal position. It will, however, drop back as soon as the sound is withdrawn unless it be supported by means of a pessary. If the tumour be anything but the uterus, the sound will pass in its proper direction—viz., with the concavity looking to the pubes, while the tumour itself will not be influenced by rotating the instrument.

Great difference of opinion exists among practitioners

as to the best mode of treating cases of retroflexion. Dr. Meadows would endeavour to cure the inflammatory condition, which is the chief cause of the patient's sufferings, before having recourse to mechanical treatment. I, however, think that where a pessary can be borne, the restoration of the organ to, and the supporting of it in, its proper position, will materially aid us in our efforts to effect a cure. Almost the only instrument that I use for the purpose of supporting the retroflected womb, is the modification of the ring pessary, known as Hodge's lever pessary; it is oblong in shape, and has a double curve. (Plate iv.) When introduced it should lie in the position shown in the engraving. The best are those made of vulcanised indiarubber, on which the secretions of the vagina take no effect. I prefer, also, those with transverse bars; the cervix projects through the space behind the posterior one of these. Care must always be taken to select a pessary of suitable size and length; for if one be introduced which is too long, it will cause much discomfort, and perhaps actual pain; while, if the instrument be too small it will slip out; you must therefore have a number of these pessaries of various sizes by you, and remember that the vagina varies greatly in size in different women. A properly fitting pessary generally affords immediate relief to the patient, and may be left *in situ* for several weeks, or even months. I always, however, recommend patients to have it removed after the lapse of ten or twelve weeks, and not to have it replaced for a week. By adopting this precaution, all danger of unpleasant consequences following its use will be obviated. Should, however, the uterus be so tender to the touch that the pressure of a pessary cannot be borne, I first endeavour to relieve that condition by local depletion, effected by puncturing the cervix; but leeching will no doubt do equally well if you prefer that method, the greatest relief often follows this practice. Dr. Hall considers repeated blood-letting, effected by puncturing the cervix, to be sufficient alone for the cure of flexions. This assertion is however too general: it is occasionally, but not generally sufficient. I always use it as an adjunct, supporting the cervix by means of the pessary, and subsequently endeavouring to bring the organ back to its normal condition by local depletion, practised at intervals of a few days.

Finally, I would urge on you the necessity of bearing in mind that cases of retroflexion are occasionally met with which seem to cause neither distress, nor even in convenience, to the patient, and that such cases should not on any account be interfered with.

But the uterus, as mentioned at the commencement of this lecture, may be displaced in other directions besides backwards; the fundus may be thrown forward towards the pubes, the os being drawn upward, and looking somewhat towards the rectum. Antelexion, as this displacement is termed, is of less frequent occurrence, and is less amenable to treatment, than retroflexion; but it seldom produces such distressing symptoms as the latter does. I do not think either that the flexion is ever so marked as in the other—indeed, I believe that many of the recorded instances of this displacement were merely cases in which the natural inclination of the uterus forward became excessive, the womb not being *bent* on itself, but merely sloping more anteriorly than was normal. In these cases, if tenderness on pressure, indicating the existence of inflammation, be present, I puncture the cervix just as I do in cases of retroflexion, but I seldom use any pessary. Dr. Graily Hewitt has invented a double-curved one for the purpose of supporting the antelected uterus. I have not as yet tried it—indeed, the cases requiring support are not numerous.

Prolapse of the uterus is another displacement of frequent occurrence, productive of great discomfort, and in aggravated cases of actual suffering, but it is by no means so common as is supposed. Great numbers of women, especially of the very poorer classes, present themselves among the extern patients, stating that "the womb is

coming down," but on examination the uterus is found to be in its normal position, the sensation of dragging and bearing down being due to a relaxed condition of the anterior wall of the vagina, which often protrudes slightly beyond the vulva, and is mistaken by the patient for the womb itself. When this proceeds to any extent, the prolapsed part contains a portion of the posterior wall of the bladder, and constitutes the affection known as cystocele. Prolapse may be partial or complete: by the former we understand a protrusion of the cervix to a greater or less extent beyond the vulva; by the latter, the rarer form of complete extrusion of the whole uterus. When this occurs the vagina is everted, a portion of the bladder, and sometimes of the rectum also, being drawn down with it. In old standing cases of complete prolapse the mass hanging outside the vulva is frequently enormous; in them the surface of the tumour, especially in the

Complete Prolapsia with extensive Ulceration of the Os and Vagina (after McClintock).

neighbourhood of the os uteri, is covered with extensive patches of ulceration, while the mucous membrane of the vagina, is so altered by exposure and the effects of friction as to resemble true skin. The annexed wood-cut illustrates this condition. The patient from whom the drawing was made was under the care of my friend Dr. McClintock, in the Rotundo Hospital; the prolapse was of twenty-five years' standing. Details of the case will be found in Dr. McClintock's work on "Diseases of Women," p. 59.

These aggravated cases are not, however, of very frequent occurrence; more commonly when the patient stands for any length of time a portion of the cervix protrudes, receding however when the patient assumes the recumbent posture. If, however, the case be neglected, the protrusion is sure to become gradually larger, and may in time remain permanently outside the vulva.

Numerous kinds of pessaries have been invented, with the view of supporting the uterus and retaining it in its proper position. The best for general purposes is Hodges's, the same which I recommend in cases of retroflexion. You should however, in cases of prolapse, choose one with transverse bars; they prevent the anterior wall of the vagina from coming down, and as this is the part which first protrudes, it is important to support it. Another pessary in general use is the disc of box wood, or vulcanised India rubber; those made of the latter are much to be preferred. Globular ones are also employed. I dislike them very much; they are difficult to remove, and sometimes, as occurred with the patient we had here the other day, can only be extracted with the aid of a blade of the forceps, or by the instrument devised by Dr. McClintock for this purpose, an instrument very like a corkscrew in appearance, the spiral end of which is to be introduced through one of the holes in the pessary, and

traction then made. ("Diseases of Women," p. 71.) But if the prolapse be large, or the perineum much relaxed, or if it have been destroyed by laceration, occurring during labour, no matter what pessary you use, it will be forced out by the pressure constantly exerted on it. In such cases unless you narrow the vagina by operative means, you can do but little for your patient.

This operation, originally suggested by Dr. Marshall Hall, has been modified and improved by Dr. Marion Sims. He removes the mucous membrane in the form of a V from the anterior wall of the vagina, the apex being near the neck of the bladder, and the two arms extending up on the sides of the cervix uteri. These denuded surfaces he then brings together by silver-wire sutures, passed transversely, thus including a longitudinal fold of the vagina, which has the effect of narrowing that canal considerably. In some of his more recent operations Dr. Sims united the base of the V by a transverse dissection. ("Uterine Surgery," p. 311). This without doubt is the best operation which can be performed, and holds out the greatest promise of a radical cure. But I must refer you to the work from which I have just quoted for further information on this point, for it is impossible for me at present to enter fully into this subject. If there be great deficiency on the perineum, or if prolapse of the rectum (Rectocele) exist, it may be necessary subsequently to perform an operation similar in principle, but differing in details, on the posterior wall of the vagina. This proceeding is advocated by Mr. Baker Brown. The first of these operations has for its object the narrowing of the vaginal canal, the latter the restoration of the perineum; but neither of them has any direct influence on the uterus itself, which is often enlarged to a great degree. This enlargement in many cases is confined to the vaginal portion of the cervix, which becomes greatly elongated, while in not a few there is little if any descent of the uterus itself. You saw a well-marked example of this in the woman who presented herself among the extern patients the other day. She is an over-worked needlewoman. She sits, she tells you, sewing for fourteen or fifteen hours a day. She suffers from partial prolapse of the uterus, with great elongation of the cervix, the vaginal portion measuring at least two inches in length. She is unmarried. The perineum is perfect and the vagina narrow, therefore, in her case, neither of the operations just mentioned is applicable, but, on the other hand, in her you would effect much good by amputating the cervix. I have urged this on her several times, but she is unwilling to submit to the operation; probably the inconvenience and distress which she suffers will by-and-by compel her to do so. The operation is a simple one: you can without difficulty remove the hypertrophied part by means of an *écraseur*. Great care, however, is necessary to prevent any portion of the wall of the vagina getting under the chain, for if this point be not attended to it is possible that a fold of the peritoneum, or, as occurred in a recently recorded case, a portion of the posterior wall of the bladder, may be drawn in and removed, and give rise to very serious and probably fatal consequences. However, before having recourse to any operation, you should in all cases try palliative means. It is sometimes astonishing how much can be done by rest in the horizontal posture, by astringent injections, and by the judicious use of pessaries.

## THE UNITY OF THE SYPHILITIC VIRUS.

By S. MESSENGER BRADLEY, F.R.C.S.,

Lecturer on Human and Comparative Anatomy, Royal School of Medicine and Surgery, Manchester.

At the recent meeting of the British Medical Association, at Plymouth, a paper of mine on the above subject was read,\* giving the details of three cases in which I

\* An abstract of this paper appeared in *Medical Press*, August 23, 1871.

had succeeded in producing an auto-inoculable, freely suppurating, non-infecting, soft chancre, by direct inoculation from a true infecting sore. Two of these cases occurred in guinea-pigs, the remaining one in a kitten; in each instance I had taken a scraping from the surface of the un irritated sore, and produced the mature resultant chancre within a week from the date of inoculation. As these experiments were made more than three months ago, the possibility of being mistaken as to the absence of constitutional taint is removed, when it is remembered that in two instances we are dealing with rodents, in whom the disease, if once implanted, runs a very rapid course. I am now able to detail a fourth successful case of inoculation, also in a guinea-pig; but I admit that it is yet too soon to speak with certainty as to the non-infection of the general system. It so closely resembles my other cases however, that I regard this (non-infection) as in the highest degree probable. On July 20, 1871, I inoculated a guinea-pig on the inner surface of the left thigh with matter taken from a hard chancre. The subject who supplied me with the virus was a girl, aged seventeen, at the time an in-patient at the Manchester Workhouse. The chancre was situated in the vestibule, it had a distinct hard base, it secreted scantily, and was accompanied by multiple inguinal adenopathy. There was also present a general copper-coloured papular eruption. She had discovered the sore three weeks before, but at the time of my seeing her it had not begun to heal.

The third day after inoculation the puncture on the guinea-pig's thigh was raised and red, on the fifth day there was a distinct pustule, which on the seventh had left a freely suppurating circular sore; with matter taken from this, I successfully inoculated the opposite thigh in two places. Up to the present date, August 21, 1871, there has been no adenopathy, or any trace of constitutional taint.

If we briefly sum up the evidence in favour of the unity of the syphilitic poison, I believe we must consider it as conclusive. In the first place we have the admission of the most experienced observers, that sores which, so far as our present means of observation go, must be considered as soft, are occasionally followed by constitutional symptoms, and again that sores with every feature of the true infecting chancre are not invariably followed by secondaries. Much evidence to this effect will be found in the "Introduction to the Report of the Committee appointed by the Secretary of State for War, and the Board of Admiralty, to enquire into the Pathology and Treatment of the Venereal Disease," and also in the various articles "On the Nature of the Venereal Poison," by Dr. Morgan, published in the pages of the MEDICAL PRESS AND CIRCULAR. In the second place, multiple adenopathy, which many observers regard as more certain evidence of constitutional infection than the character of the initial lesion, does not always occur where systemic poisoning has taken place. Bassereau mentions 120 cases of syphilitic erythema where the initial lesion was neither accompanied or followed by adenopathy. This, too, Mr. Berkeley Hill, a firm dualist, admits, for, speaking of certain cases, he says, "This makes it probable that the glands in a small number of cases escape alteration."—"Syphilis and Local Contagious Disorders," page 78.) In the third place it is admitted that in syphilitised subjects inoculation with the matter of an infecting sore, or with the secretion from a moist secondary, will occasionally produce an ulcer, and that the inoculated sore so produced is invariably soft. M. Rollet writing on this subject says, "M. Ricord arriva à cette conclusion que le chancre induré lorsqu'on réussit à l'inoculer à un sujet syphilitique, se manifeste chez à dernier avec les caractères du chancre mou."—(Rollet, "Maladies Veneriennes," page 665.) In the fourth place there is the testimony afforded by the experiments which I have made upon the lower animals.

It is quite true that the interchange of the two lesi

takes place very rarely: thus the great majority of my experiments failed. I do not know exactly what the proportion was, but I should say about 95 per cent. of the operations gave negative results.\* It is quite true too that in an immense majority of cases, the skillful surgeon will be correct in prognosing constitutional immunity in cases of the soft chancre, and constitutional infection in cases of the hard sore. It is quite true in a word that the poison of syphilis has developed into two well-marked varieties, which, as a rule, "breed true," but in the face of such positive evidence as that which I adduce, it is impossible to claim more than the position of a variety for the soft chancre. It seems to me that this fact of the original unity of the syphilitic virus taken together with the well-marked double type, into which it has now divaricated, is interesting too in affording an adumbration of the general evolution of disease. I shall perhaps explain my meaning more clearly by sketching the possible history of venereal disease. Once upon a time, for pathological time so to speak is as vague as geological chronology, we will imagine that gonorrhœa was evolved from, or let us say commenced in, a traumatic urethritis, which was soon transmitted from one sex to the other, and from that time assumed a persistent type. Dirt, low vitality, &c., prepare a suitable soil for the gonorrhœal matter which, after a time produces an ulcer in the readily abraded vaginal mucous membrane. The matter which this ulcer secretes is more virulent than the former, and tends to produce an ulcer like itself. The same factors which evolved the ulcer from the urethritis operate again, and so increase its poisonous qualities, that its cell elements become capable of self multiplication in the blood, producing at length a true constitutional malady. This, of course, is purely imaginary, but it is probable that when the "special creation hypothesis" has given way to the "evolution hypothesis" in disease, as it is doing in natural history, we shall adopt some such theory as the above to account for the origin of different diseases. Leaving the improved, however, we find a parallel to the history of syphilis in the history of the epiphytes, or vegetable parasites. It may be held as settled, that the various epiphytes which infest the human body have a common origin, e.g., that the aerial spores of penicillium, that torula, and sarcina, and the various tinea, &c., are all the offspring of the same vegetable cell; and yet it is a clinical fact that, their mutual interchange is scarcely ever witnessed in the human subject. Is it not possible that the same causes which operate to change these low forms of vegetable life, such as differences in the nature of the soil, and the age, &c., of the seed, are also the principal agents in determining the character of syphilis? Though not as yet demonstrable, such a solution seems to me in the highest degree probable.

## DIARRHŒA AND CHOLERA :

### THEIR SUCCESSFUL TREATMENT BY MEANS OF THE SPINAL ICE-BAG.

#### A SUMMARY RECORD OF CASES AND RESULTS.

By JOHN CHAPMAN, M.D., M.R.C.P.,  
Physician to the Farringdon Dispensary.

(Continued from Page 227.)

Is the treatment of cholera, as, indeed, of diarrhœa, when of an especially severe type, and threatening to merge into cholera, an extremely important remedy, co-operative

\* Von Roosbrock, on the authority of Rollet, has proved by experiments that if the discharge of gonorrhœal ophthalmia be deprived of its pus globules by filtration, the remaining fluid is innocuous, and Rollet states that he has obtained like results with the pus of soft chancres.—(Bumstead on "Venereal Diseases," page 346.) It is very probable that the small quantity of pus present in my experiments was a common, but as I have shown not invariable, cause of negative results.

with that of the Spinal Ice-bag, consists in the simultaneous application of heat to the general surface of the body. I am aware that heat when thus applied, by whatever method, has generally failed to recover patients from collapse, except in favourable cases, in most of which recovery would have occurred without any treatment at all. The reason of this is, that heat so applied does not, and cannot, affect the condition of the blood-vessels ramifying throughout the spinal and sympathetic nervous centres in any considerable degree. Hence, the hyperemia of those centres being allowed to persist, the arterial spasms throughout the body, due to the excessive energy of the sympathetic centres, remain unsubdued, and are too strong to admit of blood being drawn through the vessels to the periphery when heat is applied there. But if, while these spasms are being overcome by the application of ice along the spine, heat be simultaneously and energetically applied to the surface of the body, its effects will be wonderfully beneficial, because now the relaxed blood-vessels will permit the blood to pass, and the impulse given by the heat to the vital processes in the organic textures causes them again to attract blood to themselves, and thus to revive the circulation.

Moreover, these local applications of heat are more effective than might *à priori* be supposed even, from what I have just said, for they do exert a certain amount of beneficial influence on the nervous centres. In slight cases, where the vasic spasms of the extremities are distinct, but not strong, vigorous friction or heat, so applied to one hand or foot as to make it thoroughly warm, will generally so act, as already explained, on the nervous centres related to the limb as to cause them, by reflex action, to relax the arteries of, and thus to insure warmth in, the corresponding limb. And, deductively, I conclude that this law obtains in every segment of the body.

The importance of making the utmost effort to facilitate the operation of the Spinal Ice-bag in relaxing the arterial spasms throughout the surface of the body is attested by a fact mentioned to me by the late Dr. Brinton—viz., that if equal doses of opium be given to two dogs of equal size, and then if one dog be kept in a room at a low temperature—say 50°, and the other in a room of a higher temperature—say 70°, the former will die, but the latter will live. The cause of this difference in the fate of the two animals lies, I doubt not, in the fact that the constricting action of the opium on the peripheral arteries was assisted by the external cold in the case of the dog placed in the cold room; whereas, the same action was impeded by the external warmth in the case of the dog placed in the warm room, and thus the circulation was kept up sufficiently to sustain life until the poison had been excreted, or its force expended. The most convenient and effective method of applying heat is that by means of hot water contained in India-rubber bags.

It is impossible to state too emphatically that *in cases of cholera under treatment by my method, the life of each patient depends in great measure on the nurse in attendance. The remedial power of the Spinal Ice-bag can only be exerted while it is rightly applied. It must be kept exactly along the centre of the spine; if it is not it will do harm, and had better not be used at all.* The only method known to me of keeping it in its place which does not involve the incessant watching on the part of the nurse, is that of employing the "Ice-bag Jacket," described at page 33 of my volume on "Diarrhoea and Cholera;" and even then in cases of extreme restlessness slight readjustment may be necessary occasionally. To insure the proper application of the bag; to keep each of its cells, when all are used, duly filled, and duly replenished, when needful, with ice; to keep the surface of the patient clean and dry; to insure the continuous application of heat along the four extremities and over the surface of the body; and duly to attend to the other and various wants of even one patient—all this is a considerable task, and one which demands for its adequate fulfilment considerable intelligence, a resolute will, and a strong sense of duty. I am painfully aware

how difficult it is to secure these qualities in attendants on the sick, and how strong in the eyes of many will seem the objection to my method, that its successful practice necessitates not only first-class nurses, but a great many of them in proportion to the number of patients whom they attend. To this objection I can only reply; No easy method of curing cholera is yet known; drugs have been proved useless; and it behoves all whom the matter may concern to ask themselves, "Is the life of the patient in question worth saving at the cost of providing the conditions mentioned?" If the answer is affirmative—then, as in cases of cholera, life is destroyed very swiftly, it will be well to insure those conditions, not only completely, but promptly; an hour, half an hour, nay, a few minutes lost in delay may seal the fate of the sufferer, whose life might have been saved by swift as well as judicious action.

#### Cases of Cholera.

CASE I.—I was summoned in the morning of March 14th, 1865, to see Mrs. D. Just as I reached her room at 7.30 a.m. she had been got up to the night-chair. Immediately she rose from the chair she stood still and speechless, and anxiously beckoned to her attendant, who rushed to her and caught her as she was falling. She was got on to the bed, where she lay for some time as if dead. The window having been opened, she was raised and held up, when she soon recovered from what seemed to be a fainting fit. At 8 a.m. she had another motion, and experienced such extreme dyspnoea, that she appeared to have quite lost the power of breathing. She gasped; her countenance rapidly changed—became quite dark-coloured and remarkably pinched and contracted. Her hands were purple and icy cold. The attack began two days previously with diarrhoea, which had continued ever since. During the night of the 13th the patient was purged several times, became alarmingly weak, and suffered much from cramps in the abdomen and lower extremities, which quite doubled her up. While I was with her, between 8 and 8.30 a.m. she was agonised with cramps, especially in the thighs, and had vomited repeatedly in the morning.

Not until 8.30 a.m. was it possible to procure ice. I applied it immediately, *and within five minutes she was in a placid sleep!* She slept forty-five minutes, and was then woken up by the leaking of the ice-bag. She had another motion immediately—nothing but a serous-like fluid, with flakes of mucous floating in it—a true "rice-water stool."

The treatment of this patient was continued by means of the Spinal Ice-bag alone—no medicines—and although she was fearfully weak during the 15th, 16th, and 17th, the choleraic symptoms were completely controlled, and she rapidly and completely recovered.

[Cases II. to V. inclusive were kindly placed in my hands for treatment either by Dr. Cheeseman or by Mr. Bencraft, surgeon, of Southampton.

CASE II.—Mrs. F., æt. twenty-nine, eight months pregnant, living in one of the worst parts of Southampton, was first seen by me on October 4th, 11.30 a.m., 1865. Has had diarrhoea about ten days. On the 2nd inst., in the afternoon, felt faint, and at 7 p.m. took to her bed. Had previously begun to be purged "dreadful." Since then has been purged continually every ten minutes, or oftener. Cramps have occurred at intervals during the ten days, but on Monday night they became very bad, recurring continually, has not had five minutes' sleep at a time for them; skin cool, but not very cold. Ate an egg this morning, and, as her first act of vomiting, has just thrown it up. No headache, but is very giddy; cannot stand one moment. Head decidedly cold; eyes deeply sunken; tongue cool. "Feels," she says, "tight in the chest, and hot in myself." Very slight pain in bowels; passes water. Pulse 108, thin, and very feeble. Applied ice at 11.45 a.m. along the whole spine, and ordered it to be removed at once if any hypogastric pain were experienced. 2.45 p.m.—Was soothed during the first forty minutes, then

begin to have pain in the region of the womb, but continued the ice; cramps much lessened; bowels moved but twice; has been sick twice; pulse 104. Continue the ice every other half-hour, and give beef-tea. 7.15 p.m.—Bowels moved twice, sick twice, but retained the beef-tea. Cramps have subsided, but still has pain in the hypogastric region and down the thighs; is very comfortably warm all over. To apply the ice only between the scapulae every other half-hour as before: to remove it at once if internal pain is induced. 11.15.—Has slept several times during the evening. Hypogastric pain continues; bowels moved once; sick twice; continue as before.

5th, 8.30 a.m.—Bowels moved twice; sick four times, twice provoked by medicine prescribed before I saw the patient, and given without my knowledge. Pulse stronger; warm all over; no cramps. Still has dull pain in hypogastric and lumbar regions; nothing however of the nature of spasms. Has retained her beef-tea, and says the ice comforts her. To re-apply it until it melts along the whole spine, unless hypogastric pains increase. 5 p.m.—Is altogether better; pain lessened; no cramps; warm all over; bowels moved but once; stool decidedly fecal; has vomited a little after drinking; sleeps often, and feels rather heavy in the head.

7th, 9.30 a.m.—Used ice three times since last evening. Has been sick three times. The bowels have not been moved since yesterday morning. Still warm; no cramps; pulse 104; has eaten two eggs and some fish. To use ice only if coldness, cramps, sickness, or diarrhoea should recur. To eat anything she may fancy. 10 p.m.—Has been much better all day; neither sickness nor movement of the bowels. Is now asleep.

8th, 9 a.m.—In the middle of the night began to "wander;" and got up. Does not answer questions coherently this morning. The eyes have a peculiar aspect, as if expressive of cerebral oppression. Head, chest, and extremities warm; pulse rather strong and rapid. She has been neither sick nor purged. Loud bronchial breathing, but no respiratory murmur at back of each lung; breathing rather laboured. I thought the breath had a diabetic smell. Still no movement of bowels. To discontinue the ice, and to apply heat between the scapulae, and to renew the warm water in the bag every hour. 4 p.m.—The heat gave immediate relief, both to the head and chest. In a few minutes after its first application she became quite coherent, broke out in a perspiration, and felt much better. Has had a long sleep—the longest since she has been ill. Says, "I'm wonderfully better; I only want a cup of tea to be all right now." Still neither vomiting nor purging. To renew water-bag at intervals of ninety minutes.

9th, 9 a.m.—Feels a great deal better in herself; slept two or three hours; still no sickness and no movement of the bowels; passes urine freely; skin cool; pulse 112; tongue coated. To continue water-bag once every two hours, and to have a saline mixture. 4 p.m.—Still better and stronger; has slept much; tongue cleaner; no sickness; bowels still unmoved. Says she feels now that she only wants plenty of good food. On this occasion I ordered the use of the water-bag to be discontinued, and took my leave.

*Comment.*—As this woman is pregnant, peculiar care and patience were needed in her treatment by means of ice, otherwise a miscarriage must have been induced. Foreseeing before ice was first applied the danger of its prolonged use at one time, I ordered its removal at once if hypogastric pains were caused by it. It will be seen that my precautions were needful, but that by careful management such tolerance of the ice was ultimately established as to enable me to overcome all symptoms of her malady. The experience of the effects of the heat in restoring sanity, inducing sleep, causing perspiration, and relieving the lungs is not less striking than instructive.

CASE III.—Mrs. L., æt. twenty-nine, first seen October 6th, 1865, at 4 p.m. Began to have diarrhoea and vomit-

ing at 6 a.m., stools being yellow. Cramps began at 10 a.m.; at 11 a.m. the skin became cold and discoloured. Symptoms gradually increased. At 4 p.m., when seen by myself, Mr. Bencraft, and Dr. Welsh, she exhibited the choleraic countenance in a very striking degree: eyes deeply sunken; lips blue; the whole surface of the body cold; cramps violent; rice-water purging and vomiting. Ice ordered to be applied continually. 10 p.m.—Decidedly improved. Markedly warmer; cramps and sickness much lessened. The cramps only recurred when the ice had melted and the bag had become warm.

October 7th, 10 a.m.—Aspect and voice much improved; lips red; whole surface of body quite warm; pulse 100. Cramps only occurred once—when the bag had become warm. Bowels moved three times; vomited once. To continue ice as before. 8 p.m.—Body nice and warm. Pulse 94, fuller and stronger; slightly sick once; no cramps; bowels moved twice; the stools have a fecal smell. Very thirsty and weak; indisposed to take nourishment. Had some beef-tea and milk, and kept it. To apply ice till it melts, then omit for half an hour, then repeat it in the same way.

8th, 10.30 a.m.—Has had rather a restless night, wanting sleep, and troubled with hicough. Warm all over. Pulse 90. No vomiting; bowels moved but once; no cramps. To apply warm water-bag along cervical and upper dorsal region, and to renew it every two hours. R. Ferri et quinae citratis, gr. v, ter die. 11 a.m.—Called again and found her asleep. Without giving further details, I may say that this patient steadily improved and completely recovered.

CASE IV.—Ellen S., æt. fifteen, first seen October 6th, 12 p.m. 1865. Began to menstruate five months ago. Of late years has had pretty good health, but has always been delicate in the chest; eight years ago had a severe attack of diarrhoea and "slow fever." This morning, at 7.30, had a stool, and complained of pains in her chest and stomach. She continued to be purged and to vomit at times, and at 4 p.m. assumed the ghastly cholera aspect, and said she thought she was going to die. Since then the purging and vomiting have been almost incessant. She is very cold all over, the wrists and tongue especially so; the head alternately cold and hot. Pulse almost wholly imperceptible; cold perspirations; very bad cramps; rice-water stools. When first seen the peculiar choleraic countenance was more striking than I had seen before; it was appallingly deathlike. Had "a bilious pill" at 10.30 a.m., a pill of calomel and opium (gr. ʒ of the latter) at 11.30 a.m. I ordered ice to be applied to the whole spine every two and a half hours.

October 7th, 9 a.m.—Is strikingly better; warm all over; tongue considerably warmer; pulse very distinct, 116; head comfortable; countenance immensely improved; no cramps at all; has vomited but once. The faeces, which are still passed under her, have a distinct fecal smell. Has had a cup of tea. Ordered to apply ice during an hour; then to omit it half-an-hour; then to resume it for the hour, and so continue. To have beef-tea as often as she can take it. 2 p.m.—Continues warm; tongue warm; no cramps. Has been sick once, at 9.30; not since. Bowels not moved since 11 a.m. Has dozed a little; no headache. Has had half a cup of beef-tea, and has kept it. 8.30 p.m.—Thinks she does not feel quite so well. Warm all over, except the feet; pulse 104; no cramps; sick once; bowels moved once; stool fecal. Has had two half cups of beef-tea, and has kept them. Had the ice on every alternate hour. To continue the ice an hour, omit half an hour, and repeat continually in this way.

8th, 10 a.m.—Is still warm all over, especially the chest. Pulse 116. Has been sick and purged ten or twelve times during the night. The last stool was quite of the rice-water character, and contained a large round worm which was dead. She complains of pain in the chest, and I cannot hear respiratory murmur at the lower part of the back of the lungs. Has recently slept about half an hour. To

apply ice to lumbar region only, and continually. To apply warm water between the scapulae every hour. 4 p.m.—Found her asleep. Feels easier in the chest; vomiting and purging much lessened; stools have strong fecal odour. Has had more beef-tea. Continue. 10 p.m.—Still better; has slept an hour; pulse 100. Mr. Bencraft, who saw her with me, is struck with the improvement in her appearance. She soon became quite well.

**CASE V.**—Mr. B., a strong man, accustomed to work at the Docks, was attacked on the morning of October 8th, 1865. I saw him with Mr. Bencraft in the evening of the same day, when he complained of incessant vomiting, purging, and cramps, and evinced great anxiety and distress; but though the skin was rather cool, it was not cold; and as therefore no marked algide symptoms were developed, the case was not thought to exhibit the characteristic symptoms of cholera in a form so decided as to be a desirable one for testing the efficacy of my method of treatment. He was therefore treated by medicine only.

October 9th, 11 a.m.—I was again requested to see the patient, the algide symptoms being now very marked. Indeed all the characteristic evidences of cholera were present; but just before I reached the patient, Dr. Lake had applied an Ice-bag along the spine. I did not see this patient again. Dr. Bullar, however, who called upon me the same day just as I was leaving Southampton, informed me that by twelve o'clock a favourable change in the patient was observable, and that he was already becoming warm; and I afterwards received a note from Mr. Bencraft, dated 9 p.m. the same evening, in which he says:—"B. is much better, warm all over, a capital pulse, but still sick; no cramps." He quite recovered.

**CASE VI.** (under the care of Mr. Bencraft).—Kate Leggett, *æt.* seven, became ill on the night of July 13th, 1866, and was first seen at 9 a.m. on the 14th, when she had all the symptoms of cholera, and was quite pulseless. Ice was applied continuously, and reaction was perfectly established by 2 p.m. of the same day; a good pulse having returned, she continued to do well, and has quite recovered.

**CASE VII.** (under the care of Mr. Bencraft).—Mary Ann Gregory, *æt.* twelve, was attacked July 12th, 1866, at 11 p.m., with vomiting and purging, and cramps in the legs, which continued to increase, and in the afternoon of the 13th she was collapsed and livid. The Spinal Ice-bag was applied at 1.30 p.m., the cramps and vomiting speedily ceased, and by 5 a.m., of July 14th the purging had ceased also. The ice was continued uninterruptedly till I saw her in the evening of this day. She was then warm all over, had a good pulse, and was seemingly out of danger. I advised that the ice should now be applied at intervals, and that ice should be given internally. July 15th.—Continues to improve; the Ice-bag was applied once this morning. Finding the head hot, I ordered warmth to the cervical region, the use of the Ice-bag being discontinued. The patient steadily recovered.

**CASE VIII.** (under the care of Mr. Bencraft, and treated by me).—Emily Eliza Gregory, *æt.* seven, sister of the above, was attacked July 16th, 1866, at 2 a.m. with vomiting, purging, and cramps; became collapsed and quite pulseless. Ice was applied for the first time at 10 a.m., and was continued uninterruptedly until 4 p.m., when the countenance had become much less choleraic, and the vomiting, purging, and cramps were already greatly subdued. I then recommended the application of ice in the lowest cell of the Ice-bag, and in the middle one up to the top. Warmth was simultaneously applied to the extremities in this as well as in the preceding case. From this date the child continued to improve, and did well.

**CASE IX.** (under the care of Mr. Bencraft, and treated by me).—Mrs. Witt, *æt.* sixty-three, after suffering from diarrhoea for some days, while assisting to nurse the children just named, was attacked with cholera. She entered the room when I was there, suddenly sank down,

uttered an exclamation, became deathly pale, strikingly cold, the lips turning livid, and the sweat exuding in large drops over her face and upper extremities. I found her quite pulseless, her head being cold. She was carried to her own house, when it appeared there had been a discharge from her bowels as she sat. I applied ice immediately along the whole spine, and in about five minutes afterwards her pulse became distinctly perceptible, slight colour returned to her face, and in a few minutes more she said, "I am better." Ice to the spine and heat to the extremities were continued at intervals for some days. She steadily improved, and was out of danger when I left Southampton. On several occasions, when for want of ice in the house none was applied to the spine, vomiting and purging returned, to be again subdued when the Ice-bag was reapplied.

**CASE X.** (under the care of Dr. Griffin).—Mary Goodwin, *æt.* nineteen, was attacked July 12th, 1866; became collapsed and nearly pulseless. The attendant of this patient having procured ice, but having no ice bag, placed lumps of ice in a row, supported on each side by sawdust, and then caused the patient so to lie upon it that the ice came in contact with her along her spine. An Ice-bag was subsequently applied two or three days. The patient completely recovered.

**CASE XI.** (under the care of Dr. Griffin).—Charles Adams, *æt.* seven, attacked July 12th, 1866; became completely collapsed; had the Spinal Ice-bag applied "off and on" during the two days, and quite recovered.

**CASE XII.** (under the care of Dr. Griffin).—A girl, named Feltham, *æt.* six, was attacked July 19th, 1866. She became collapsed, but continued to have a slight pulse. Under the use of the spine-bag she recovered.

**CASE XIII.** (under the care of Dr. Griffin).—Mr. Willis, *æt.* fifty-six, was attacked July 18th, 1866; became collapsed, his pulse, however, continuing perceptible. He was treated by means of the Spinal Ice-bag, and recovered.

**CASE XIV.**—Penny, a girl, *æt.* about twelve, attacked July 18th, 1866, became collapsed, but continued to have a slight pulse; she was first treated by Dr. Griffin, who applied ice to her spine, and subsequently she came under my care. She recovered.

**CASE XV.** (under the care of Dr. Griffin).—George Thorn, *æt.* eleven, was attacked July 15th, 1866, with very profuse vomiting and purging (rice-water stools), and violent cramps. Ice was applied to his spine during the whole day of July 16th, and at night all active symptoms were subsided. On the 19th he was up again and at play.

**CASE XVI.** (under the care of Dr. Oliver).—A girl, named Maguire, about ten years old, had been suffering for some days from cholera; she was treated successively by astringents, calomel, and arsenic, each of which failed to arrest the sickness. She was, therefore, placed under my care. I treated her by means of ice along the spine, by which the vomiting was speedily and completely subdued. The girl steadily regained her appetite and strength.

**CASE XVII.** (under the care of Dr. Cheeseman).—Eliza Randell, attacked July 16th, 1866, with cramps, vomiting, purging, and partial collapse. Dr. Cheeseman gave her a grain of calomel every half hour, and ice internally: the cramps were relieved, and the purging lessened, but the vomiting persisted. She was then treated by dilute sulphuric acid, which was also powerless to arrest the vomiting. She was therefore sent to Anspach House and placed under my care. In the evening of July 17th one bag of ice was applied along her spine, she vomited once, but expressed herself as immensely relieved and comforted by the application. She begged to have another bag during the night, which, however, the nurse did not supply. She rallied rapidly, notwithstanding, and ascribed the beginning of her improvement to the use of the ice. The next morning Dr. Cheeseman found her much better, and then, saying she was scarcely a fair case to test the efficacy of the ice, resumed her treatment by means of stimulant salines.

CASE XVIII.—This case of obstinate suppression of urine during choleraic reaction resulting in uremia and delirium, was treated by Dr. Allen, of Brighton, who kindly supplied me with the following report:—Mr. K., of Brighton, was attacked in December, 1866, with violent diarrhoea, vomiting, and cramps in the stomach and limbs, attended with intense pain. As the disease advanced the evacuations assumed completely the "rice-water" character distinctive of cholera. The eyes were sunken, the complexion and general surface of the body became dark, the fingers and nails were purple; the pulse was so weak as to be almost imperceptible; there was total suppression of urine, and intense thirst. In short, there were, as Dr. Allen said, all the symptoms of "Asiatic" cholera. During the administration of opium and stimulants which he prescribed, all the symptoms, except that of the arrest of the urinary secretion, began to subside at the end of the second day. Notwithstanding the use of diuretics of all kinds, the urine still continued suppressed at the end of a further period of fifty-two hours; and this condition was followed by the usual phenomena of uræmic poisoning, including a urinous smell of breath, hiccough, and delirium—making the case apparently hopeless. An ice-bag was then applied along the lower half of the spine, and was repeated from time to time. In half-an-hour after the first application the patient voided nearly half-a-pint of urine, loaded with albumen. Two hours afterwards he passed a pint, and during the next twenty-four hours considerably more than the usual quantity of urine, with a gradually decreasing quantity of albumen. From the time the ice was first applied the patient began to improve, and he continued to do so steadily until he had completely recovered.

WEDNESDAY, SEPTEMBER 27, 1871.

### AN UNJUST VERDICT.

THAT the office of Coroner ought to be held by a medical man has frequently enough been argued in our columns. It is therefore with double vexation that we read that a medical man was the coroner in the case in which a jury has censured a medical man in a most unwarranted way. Dr. Meeres, with a true manliness that does credit to him as a man and a physician has given to the world, and to the Profession, an account of the treatment he adopted in the case enquired into, and his reasons for it. We invite

the attention of every reader to his statements, and we assert, without fear of contradiction, that unless the reports of the proceedings that have been published are mere misrepresentations, that Dr. Meeres has suffered a gross injustice, and that the coroner, as a medical man, ought not to have allowed such a wrong to be perpetrated.

We read that Dr. Meeres only knew of the inquest an hour before it took place, and then had to go four miles in order to be present; that the coroner in a most impertinent manner warned him as to any statement he might make, and suffered it to be asked whether he was a qualified practitioner in a manner that might leave doubt in the minds of the ignorant. We do not at this moment remember the name of the medical coroner, but we have little doubt that he has not attained the high distinctions in the profession that Dr. Meeres holds, and in any case such injurious remarks, uncorrected by a medical man exercising the office of judge, towards a medical brother, are enough to excite the indignation of all, and make us regret that the inquest had not been presided over by a lawyer who, when such a turn was given to the inquiry, would have seen at once the injustice about to be perpetrated, and probably have adjourned in order to give Dr. Meeres the chance of producing evidence or employing legal assistance. There would have been no difficulty at all in proving that Dr. Meeres was fully justified in the treatment he adopted. In fact, the coroner, if he is, as we hear, a medical man, ought to have known this; and, knowing it, ought not to have kept back that knowledge, when the reputation of another medical man was at stake. The questions raised by this inquest are of public and professional consequence far beyond the single case. The lesson to be learned as to the possibility of injury from a particular drug, is not likely to be lost. The injury to Dr. Meeres will, we trust, not be permanent. We congratulate him on his bearing in a trial that must be most painful to any man, but which might happen to any practitioner. We exonerate him from all blame, and assure him of the hearty sympathy of all his brethren. We declare that his conduct contrasts most favourably with that of the other medical men in the case, and we assert that the insinuations respecting the qualifications of a man who took a high place at the London University are only worthy of scorn.

Further, we think that Justice has so completely miscarried that the Profession is entitled to some explanation from that one of its members who has obtained the office of Coroner. If medical coroners conduct inquests in the manner this appears, from the newspaper reports to have been conducted, it will be better for us to fall into the hands of lawyers.

Let Dr. Meeres speak for himself. He has written to us the following letter:—

SIR,—An account has been published in the London and Provincial papers of an inquest held on the late Miss Harriett Fowler, whose death the verdict of the coroner's jury states was caused by poison from the application of a very strong preparation of bichloride of mercury, made to the head and neck by Dr. Meeres, and the verdict adds that Dr. Meeres is very greatly to be blamed for having made the application.

I should be glad to have the opportunity, through your columns, of laying the facts of this very melancholy case before the profession. The child was between nine and ten years of age, of a fresh complexion and stoutly built.

On the 21st August she was brought to me with ringworm (tinea tonsurans) of the scalp. She had also some patches of tinea circinata on the face; for the latter no local treatment was used.

I prescribed steel wine and the use of a lotion of carbolic

acid, glycerine, and water, and directed that the head should be shaved. This comprises the whole of the treatment for the first week.

August 28th (Monday).—The disease appeared to be spreading, and I proposed as a speedy cure, the application of bichloride of mercury, as recommended by Dr. Tilbury Fox. On several previous occasions I had had recourse to this treatment with success. The application was made to each of the patches with a small camel's hair brush. A little of the solution accidentally ran down the sulcus behind the left ear. No pain whatever was felt while the patient remained in my room.

Monday evening.—The painted surfaces were blistered, including the line behind the ear. The subjacent scalp was tumid. There had been considerable pain, and there was sharp diarrhoea and sickness. The vomited matter consisted of pieces of greengage or apricot. No medicine given. Water dressing applied to the head.

Tuesday morning.—The patient had passed a restless night, and was very weak. There was relaxation of the bowels, and everything except cold water induced sickness.

Tuesday evening.—Mr. Gore saw the patient with me. There were patches of blisters on the head. The face looked pallid and puffy, and the eyelids were oedematous. There was great prostration, and tendency to diarrhoea and sickness. The gums were swollen and saliva ran from the mouth. It was only too evident to both of us that salivation had begun.

Wednesday morning.—The blisters had pretty well subsided. The parotid and submaxillary glands were considerably swollen, and saliva ran from the mouth. The tendency to diarrhoea continued, and there was great prostration of strength. Some pain complained of in opening the mouth.

Wednesday evening.—The parotid and submaxillary glands were still more enlarged. To procure sleep and allay restlessness—Liq. morphia acet., ℥ x. were given, and directions left that the dose should be repeated if sleep was not induced.

Thursday morning.—The second dose of morphia had been given, the patient had passed a quiet night and was drowsy. No further swelling about the jaws, and the diarrhoea and sickness had ceased. Coffee to be given at once, and as much nourishment as possible through the day.

Thursday evening.—The patient still rather drowsy; had taken some essence of meat, milk, and brandy and water through the day. The swelling about the jaws apparently slightly receding.

Friday morning.—The patient had taken nourishment through the night. Between seven and eight o'clock she got out of bed unassisted to go to the night-stool, and remained out several minutes. In getting into bed again she fainted, and although assistance was at hand she did not rally. No mercury was given by myself or others during the illness.

There was not at any time delirium, convulsions, or, until after the morphia had been given, drowsiness.

It is I fear indisputable that salivation and general prostration were induced by one application of an alcoholic solution of mercury, and that the patient was in fact poisoned by the mineral.

It is needless to say that this very sad case has caused me the deepest sorrow—a sorrow that will never be altogether effaced. The practice of the profession is always attended with sufficient anxiety and uncertainty, but a calamity like the present is enough to crush a man in his work.

I am, sir, your obedient servant,

EDWARD E. MEERES, M.D.

Melksham, September 12, 1871.

### THE GRAIN OF WHEAT IN THE PECK OF CHIAFF.

THE motive power of Mr. Benson Baker's tour in Dublin, in search of bad smells and sanitary grievances has been made public in his last communication to the *British Medical Journal*.

Having led up to the subject of the most preposterous exaggerations and misrepresentations as to the sanitary state of Dublin, he proceeds to say:—

"The sanitary arrangements of Ire land require to be recast." Nothing will be efficiently done for Ireland until a Ministry of Health shall be established. The

appointment of a *Medical Health Commissioner* for each of the four provinces would doubtless, in a few years, produce results as economical and humane as that which has issued from the admirable working of the Irish Dispensary and Medical Counties Acts. My friend Dr. Maunsell says, &c., &c., &c."

Who could have dreamt that the statistical fervour of Dr. Maunsell, and the virtuous horror of "his friend," the deputation should have led to such a conclusion!

By all means let us have a *Medical Health Commissioner* for Leinster and one for London if Dr. Baker likes. Indeed, let us all be *Health Commissioners*, and well-paid. Mr. Benson Baker's proposition is carried *nem dis*. Has he not conclusively shown that there is a great deal for the *Health Commissioner* to do, and that "my friend" Dr. Maunsell is the man to do it, and *sequiter*, that the public has to pay for it.

## Notes on Current Topics.

### Hypodermic Use of Morphia in Operative Midwifery.

DR. MELVIN RHORER, Assistant Demonstrator of Anatomy in the University of Louisville, now in Vienna pursuing his studies, sends the following to the *American Practitioner*: "I have in a number of instances seen turning effected long after the liquor amnii had passed by fully narcotizing the patient. I have never, however, seen the uterus brought to that desirable state of rest whereby the operation may be easily performed when the usual means of producing narcotism have been employed; that is, by chloroform or the internal exhibition of opium. I believe the sovereign remedy in such cases is the hypodermic injection of morphia. I have witnessed its good effects in a large number of cases, one of which, witnessed at the clinique of Professor Braun, I here report. The patient was a strong, healthy woman, thirty years of age, the mother of three children, at whose birth she had had no trouble. Her condition on examination was as follows: The abdomen tense and somewhat sensitive to the touch; the liquor amnii had passed seven hours previously. Her pains were recurring at short intervals; great sensibility on vaginal examination. An arm, purple and much swollen, was found in the vagina, with the corresponding shoulder deeply wedged in the pelvic cavity; the surrounding parts of a higher temperature; the patient much exhausted from pain. One sixth of a grain of morphia was injected into the linea alba, midway between the umbilicus and symphysis pubis. In five minutes the hitherto spasmodic action of the uterus was much more feeble, the intervals became longer, &c., and in twenty minutes complete rest was secured. The uterus was soft, and the shoulder moveable in the pelvic cavity. Turning was easily and quickly effected, and the child was extracted without causing contractions. By continued gentle friction on the abdomen, the uterus was again excited to activity, and in half an hour the placenta came away. Very soon afterwards the womb had contracted under the symphysis, and the patient continued to do well."

### Condemned Communists.

"COURBET," says the *Paris Journal*, "has been removed from Versailles to Tours, where he is to undergo

his sentence." Dr. Rastoul, one of the members of the Commune recently condemned, has become mad, and passes his time in uttering imprecations against Commander Gavreau, the Government Prosecutor in the third court martial. He has been removed to the hospital of the civil prison at Versailles. Jourde is in a state of great prostration, and his condition is becoming more and more critical every day.

#### A Black Town.

A REPORT has been made by Dr. Thorne Thorne, one of the inspectors of the Medical Department of the Privy Council, or rather, as it must now be termed, the medical department of the local Government Board, on the excessive mortality registered from "fevers" during the past two quarters at Dudley. An analysis of statistics shows that more than 11 per cent. of the mortality from all causes in the ten years ending 1869 has been caused by the chief infectious diseases. Diarrhoea accounts for 6 $\frac{2}{3}$  per cent. of the deaths. The infantile mortality is excessively high. The mortality tables, for 1870, taken in connection with the population prove that with a decreasing population the general death-rate has risen markedly. It was, in 1870, 25.7 per 1,000, as against 22.6 per 1,000, the average of the three preceding years. More than one-third of the deaths were those of children under one year old. The mortality from fever was double that for the large towns in England and Wales. Dr. Thorne says Dudley has many natural advantages as regards drainage, but these have not been taken advantage of. Large portions are still unsewered, slips and filth may be seen trickling down the streets; sewer ditches run through thickly inhabited districts, and many of the sewers are improperly constructed and defective. Even in some of the best streets the sewers are so ill-adapted for their purpose that they fail to drain the cellars, from which a foul and offensive fluid has, in some instances, periodically to be removed. There is no plan of sewers (Dr. Thorne adds), and nothing is known concerning them. The sewage is received after leaving Dudley into huge holes dug in the ground, and situated, at least in one case, within forty yards of a group of houses, to the inhabitants of which the stench must be intolerable. The sewage ultimately finds its way to canals and water-courses. There are about half a hundred closets in the place, otherwise the town is dependent on the midden system, and the removal of the refuse is wholly insufficient. Soakage from the huge middens takes place in the surrounding soil. The water-supply is condemned as bad in quantity and quality. A place called the Mousesweet Brook, a name which is a perversion of "mouth sweet," so proverbially sweet was its water, is now an open sewer, the contents of which are too foul to the sense of smell ever to be tested by that of taste.

The reforms urgently required in Dudley are, according to Dr. Thorne, the adoption of a thorough system of sewerage and drainage, the provision of an ample and pure water supply, the systematic removal of all excremental matter and refuse, the removal of fouling influences that at present exist in the place, the better construction of houses in accordance with the principles of the act to "provide better dwellings for artisans and labourers," the prevention of overcrowding, the introduction of a proper system of disinfection for polluted localities, the erection of hospitals for the isolation of

infectious diseases, and of a proper mortuary; and, lastly, the appointment of a well-qualified and an energetic medical officer of health.

#### The Connection between Foot-and-Mouth Disease and Small-pox.

At a late meeting of the Medico-Chirurgical Society of Montreal, Dr. F. W. Campbell read a paper in which he claimed to have proved the following:—

1st. That cattle in many ages, and different countries, have been afflicted with small-pox.

2nd. That this disease has existed among the inferior animals simultaneously with small-pox in man.

3rd. That it appeared among the cattle in England at various times during the 17th century, and that comparatively recently it has shown itself with considerable severity.

4th. That when the disease appears among the inferior animals in a malignant form, it produces by inoculation a disease of similar severity in man.

5th. That as man has received this affection from the cow, so likewise has it been produced in the cow from man.

6th. That the direct inoculation of the cow with human small-pox, has produced a mild and mitigated disease, and that such diseases reproduced by inoculation on man accords entirely in its character, in its progress, and in its protective influence with the variolæ vaccinae, as described by Dr. Jenner, thus irresistibly proving his fundamental proposition, that cow-pox and small-pox are not dissimilar, but identical, and that the vaccine disease is not the preventive, so to speak, of small-pox, but the small-pox itself.

As to the operation of vaccination, the method he invariably adopts is to make use of the *perfect scab*. He admits there is room for the exercise of much caution, and that it would be ill advised to use crusts from even healthy children without having subjected them to the following easy examination. The scab should be held up to the light, and if it presents a mahogany coloured semi-transparent centre you may put it aside for use, first having taken care to cut away from around it, the few drops of pus with epithelial scales that have dried with it. Enquiry should also be made to ascertain if the vesicle had ruptured in its course; if it has he would advise its rejection. In his early experience as a vaccinator he found many scabs, which had in their course been accompanied with considerable constitutional disturbance, all but destitute of vaccine matter, being nearly perfectly clear when examined by the light test. Enquiry as to the cause, at once showed, that there had been an early rupture of the vesicle with a copious discharge of clear liquid lymph. Having selected a crust, he shaves a portion of it down upon the back of a plate or saucer, and adds a drop or two of *cold* water, and works it into a ropy solution. Taking a quantity of this solution he smears the portion of the arm he intends to vaccinate, freely with it, and then makes what he terms the tartan cut, viz.: a number of parallel scratches, with cross scratches. Care must be taken not to draw blood freely, for when this is done, the chances are decidedly against the success of the operation. If the child is pale, use a moderately blunt lancet. If the child is florid, with a fresh looking arm, make the scratches with a fine needle. With this method, which is in many respects similar to the plan generally adopted by the profession in Montreal, Dr. Campbell had very great success, and has succeeded in getting vesicles

filled with lymph, and ending in large dark brown mahogany crusts. The method of arm-to-arm vaccination he has tried several times, but the vesicles and crusts which have followed have not shown any superiority over the first named method, while the difficulty attending it is such as to prevent its being adopted in Canada—even anything like universally—for many years to come. As to liquid lymph preserved in capillary tubes, during one whole year and a part of a second he adopted it, but for constant use has now abandoned it, being satisfied that the results obtained are not one bit better than what are always obtained from a first-class vaccine crust.

### Allopathy versus Homœopathy at Southampton.

At a recent meeting of the Southampton Guardians was elected (vice Dr. Griffin, resigned), a Homœopath named Archer to fill the vacant place. The protestations of Dr. Hearne, Mr. Davis, and one or two others were of course of no avail in the face of the all convincing logic of Mr. Archer's proposer and seconder, which we here give lest such eloquence should be lost in the comparatively localised circulation of a Southampton paper. "Mr. Archer is described as about 35 years of age, and belonged to that school known as the Homœopaths", and from what he (the proposer) had known of the old system he found that many of the old school had gone over to Homœopathy. He was, therefore, a Homœopathist, pure and simple, and would be prepared to practise that system were he elected—which would be *not only a saving of life* but money to the ratepayers also. Mr. Waters had much pleasure in seconding the proposition, believing that the new school was much better than the old one; if not, it must be bad indeed (laughter). For himself were he ill he would rather go to the Bastille than be under their treatment. He had heard that the medical gentlemen of the town had said that were Dr. (*sic?*) Archer elected they would not consult with him, but he had seen a telegram from Portsmouth from a medical gentleman, offering to come and assist Dr. Archer at any time rather than he should be thrown over."

We sincerely hope that our readers will not be visited with the nightmare, or that troubled dreams of "wasted lives and ratepayers' money" will tempt them to leave their old loves, and, like Mr. Archer, seek for fields and pastures new. Bravo, Guardians of Southampton! You are bidding well to rival even "the St. Pancras Board." We regret to be obliged to think that the guardians would not have committed themselves to the course of forcing a Homœopath on the poor had they not been encouraged by "trimming practitioners," who have held themselves out as willing to practise either system. Again it is not to be forgotten that a registered medical man, a few months ago, *proposed* a Homœopath as "an eligible candidate for a vacancy at the Southampton Dispensary." If medical men thus act, after all, the conduct of guardians who are chiefly tradesmen, is perhaps excusable.

### French Medal.

THE French War Minister on the 6th instant proposed to the National Assembly at Versailles to have a medal struck for distribution to such persons as distinguished themselves in the Ambulances during the late war. In submitting his proposal His Excellency observed that the

Cross of the Legion of Honour can only be accorded to those who have merited it; and added that a medal could be given to ladies as well to the men who had taken an important part in this work of charity and humanity. The proposal was adopted.

### Legion of Honour.

THE friends of the Rev. Dr. Smyth, D.D., will learn with satisfaction that the French Government has conferred upon him the Cross of *Chevalier de la Legion d'Honneur*, for the eminent services performed by him during both sieges of Paris. It will be in the recollection of our readers that Dr. Smyth volunteered to proceed to Paris from St. Germain when the capital was being invested; that he exerted himself when other members of his profession had quitted their posts, in administering material relief and spiritual consolation to hundreds of British subjects, and finally only quitted the city when his health had completely broken down under the severe labour, anxiety, and privations which he underwent.

He was an active member of the British Charitable Fund, or in other words of the Committee to which Mr Wallace entrusted the distribution of much of his own charity to needy British subjects, the other members being Drs. Herbert Shrimpton, and McCormack. Mr. Wallace has most deservedly been rewarded; so has the self-denying clergyman. We look for a similar recognition of the services of the then medical members, who not only distributed money to the needy, but assiduously attended the poor during periods of sickness, besides performing meritorious work in the ambulances.

### Enlarged Tonsils.

DR. RUMBOLD, of St. Louis, has treated successfully a number of cases of enlarged tonsils by injecting the glands by means of a hypodermic syringe, with a solution of iodine—iodine, gr. ij; potass. iod., ℥ij; aqua, ℥j. Generally a slight inflammation followed the injection, but soon subsided. From twelve to seventeen injections, ordinarily two a week, were sufficient to reduce the gland to its normal condition.

### The Iron Cross.

THE *Globe* says that according to a general estimate made by the German Ministry of War the number of persons who received the Iron Cross during the late war was about 40,000. Though this number may appear large, more decorations in proportion to the troops engaged were conferred during the War of Liberation. At least four times as many German soldiers were engaged in the late campaign as in those of 1813 and 1816. Yet in the earlier war about 15,700 iron crosses were distributed. The disproportion becomes still greater when we take into account the higher classes of the order. During the War of Liberation the Grand Cross was awarded to seven officers, while during the late campaign only six received it. The other classes of the Iron Cross have also been less lavishly distributed; indeed, almost twice as many were conferred in 1813 to 1815.

### The Medical Directories.

THE Editors of the "Medical Directory" have given notice that they will not in future insert qualifications

which cannot be registered under the Medical Act. It seems that there is a great increase in the number of Foreign degrees. These give no right to practise, and the editors will exclude them from the "Directory." A very proper resolution this.

Actual registration is not a condition of insertion in the Medical Directory, but the qualifications must be such as the Registrars would receive.

### On the Manufacture of Chloral.

Dr. SQUIBB, at the last annual meeting of the American Pharmaceutical Association presented a report on this subject in which he said that he had used alcohol of various degrees of strength in preparing chloral, but had met with no success, except when using absolute alcohol. In regard to the time required to complete the process it was found that the slower the current of chlorine, and the longer the time taken to produce the chloral, the better the result. About twenty-eight days are required for one operation, in which sixteen gallons of absolute alcohol weighing 92 pounds, and about a ton and a quarter of mixture of binoxide of manganese and common salt, and about the same quantity of sulphuric acid, were required to produce 160 pounds of crude hydrate of chloral.

Some accidents of an apparently trivial nature seemed to indicate that chloral is very liable to decomposition from contact with organic matter, but experiments have shown that it is not equally liable to this decomposition from all kinds of organic matter.

Under such circumstances, the only safe practice is to keep chloral as free as possible from all organic matter until we know more about it; and this particularly in view of the harm it does when given in even a partially decomposed solution. It appears to be by far the best practice to dispense it in simple watery solution in glass-stoppered vials, since in this condition it keeps indefinitely, and can be added to any desired vehicle at the time of taking, and ice-water appears to be about as good a vehicle for this, as for all saline substances, as any yet devised. When given to patients who have been long fasting, it is often found to disagree with them, or, at best, to affect them less favourably than when given near a meal, or when the gastric secretions are not in the condition of long fasting. Hence the syrup of orange-peel or the mucilage, &c., with which it is common to give it, may not be without useful effect, and those physicians who have now abandoned these mixtures for the simple solution, often, if not generally, advise their patients to eat a cracker, or take some other light food in small quantity, before or immediately after an hypnotic dose. When the medicine affects persons unfavourably, it should always be examined for hydrochloric acid by smelling and testing, and by litmus paper. Nitrate of silver is too sensitive a test, for if the solution has been for some time made, and especially when water containing organic matter is used, a cloudiness may be produced with this test which it is quite safe to disregard.

If the chloral be given under favourable circumstances, only about eight to twelve minutes elapse before the patient is asleep. If the first dose, namely, the ordinary dose of twenty or thirty grains, is not effective, a second one may be given in fifteen minutes. For if the effect is not obtained in fifteen minutes it is not likely to be ex-

perienced at all. If the second dose is inoperative, the physician may conclude that the medicine is inappropriate, since the heroic quantities that have been given have generally produced unpleasant effects. Unpleasant effects are, doubtless, often due to bad quality in the chloral. Of the various grades of it now in the market, it is, perhaps, not too much to say that a large proportion of it is unfit for use; none of it is as good as it should be, or as it will be when the makers get to know better how to make it, and when those who buy know better how to test it, and what to reject.

It will thus be seen that we are probably better off in Europe since it has been freely stated that there is very little impure chloral in the market. Yet the Report presented by Dr. Squibb seems to show a very different state of affairs in the United States. It seems to us not improbable that we have yet much to learn respecting this substance.

Freshly made solutions of chloral, especially if made from large crystals, are often more or less opalescent or milky, and this milkiness may continue for a few moments only or for many hours, but if the chloral be of good quality, the solution will sooner or later become perfectly clear, or will at once become clear on being warmed. Solution of nitrate of silver should give no reaction, or but the faintest cloudiness, with freshly made solutions of good chloral. But a little dust in the chloral, or a little organic matter in the water with which the solution may have been made, will soon give a decomposition sufficient to produce slight cloudiness with this test. If the solution has been kept in a cork-stopped bottle it will always give a cloudiness.

Chloral appears to be a hypnotic and not an anæsthetic; it produces sleep, but it will not often relieve pain when the pain arises from any organic disease. If it be inflammatory pain or pain from injury, it does not relieve it, although it sometimes forcibly superinduces sleep. A person may have suffered an injury and take a large dose and get six or seven hours' sleep, but on waking the sleep will be found to have been unrefreshing. The knowledge of how to use it is not complete, but experience is accumulating every day upon it. Our greatest interest in it, is to know how to select, keep, and dispense it; as it absorbs moisture and becomes moist in a damp day, and becomes the opposite in a dry wind. It is liable to decomposition under conditions not yet well known.

### Lunacy in Ireland.

THE inspectors of Lunatic Asylums in their report just issued, state that the statistics of the year 1870, show an apparent increase in the total number of insane persons in the country, as contrasted with those of the previous year.

It thus appears that the inmates of public—that is, of district lunatic asylums, have increased within the year by 347 insane persons, while the returns of lunatics at large, obtained through the Royal Irish Constabulary, exhibit an addition of 357 to the numbers returned through the same channel in 1869. A falling off of 153 appears as regards the lunatic and idiot classes resident in poor-houses. There was only one lunatic confined in gaol at the end of the year.

With reference to the considerable apparent increase of the insane who are not located in any aylum or other

place specially adapted for them, it may be observed that on no former occasion were these returns obtained for two consecutive years, and hence it may have arisen in many instances that the constabulary were enabled to furnish a fuller and more complete return with the information and experience of the previous year to assist them than when making a similar one at intervals of two, three, or five years, as heretofore.

The increase in the number of lunatics in district asylums is natural and was to be looked for, the accommodation for the classes of insane supported at the public expense having been considerably extended within the last few years, so that these institutions have now, in round numbers, provision for 7,600 inmates.

The diminution observable in poorhouses is accounted for by the number of insane persons transferred from them to the various asylums during the year. The term insane is here used in a general sense, and applies, we regret to say, indiscriminately to the idiotic and demented, as well as to the lunatic classes, many of whom, when they become a little troublesome to those in charge of them, are sent to asylums, without any reference to their fitness for treatment in institutions for the insane, or consideration for the additional expenditure entailed upon the district by placing persons in expensive curative establishments who cannot possibly derive any benefit therefrom, and who, with due care and attention, could be very well and suitably provided for in the wards of a poorhouse.

#### Harvey.

In 1878, the Tercentenary of the discovery of the circulation of the blood will be completed, and his native town, Folkestone, has already inaugurated a subscription for a suitable monument. At a public meeting reported in the *Folkestone Express*, we find that Mr. Simon who was on a visit to Folkestone, took part in the proceedings, and the profession was otherwise well represented. We naturally feel a lively interest in the proposal, and have much pleasure in noting its early success. It was unanimously resolved

That subscription lists be opened at the Town Hall, National Provincial Bank, Pavilion, and Libraries in Folkestone, and also in London and other places (to be selected by the Committee) in aid of the object, and that all funds collected be placed to the credit of an account to be opened at the Bank of England, Burlington Gardens, London, with "The Harvey Memorial Committee."

We have, no doubt, the response will be liberal, and that when the time arrives, one of our great worthies will be worthily honoured in his native town. Honour to Folkestone for having taken time by the forelock in so good a work.

#### The Adulteration of Beer.

SEVERAL cases have lately been reported from Leeds and elsewhere of publicans being heavily fined, two in no less sums than £50 each, for adulterating their beer with grains of paradise; and another has had to pay a still heavier fine of £75 for having a large quantity of this obnoxious drug in his possession. *The Standard* considers that these and other recent revelations go far to demonstrate that the whole question of the adulteration of our food and drink must be thoroughly investigated, and dealt with by some comprehensive legislation.

#### Lunacy Expenditure in Ireland.

THE cost of support and maintenance in District Lunatic Asylums for the year 1870, was £150,964, and exceeds that of the preceding year by £10,930. This increase is caused in the first place by the additional number of patients to be supported, namely, 347, which, at the average rate of maintenance per head, gives £8,088; the actual advance, therefore, in the gross expenditure has been but £2,742.

#### Vaccino-Maniac Logic.

AT Glasgow last week a person named Gibbs, whose trade it is to stir up agitation against the law of vaccination, in the course of an address said, that all benevolent persons should refuse to subscribe to hospitals where such an insane practice as vaccination was carried on. He referred to Sir William Jenner having advised the Queen and Royal Family to be re-vaccinated. The consequence of her Majesty having undergone that operation was apparent now, for Dr. Lister had been suddenly called to Balmoral to perform an operation upon her arm. *He did not know the precise nature of the malady*, but at any rate it was an abscess, and *he thought it was not at all improbable that the Queen's ailment was the consequence of re-vaccination*. Sir William Jenner no doubt acted in ignorance in giving her Majesty such advice, but many persons were obliged to leave the country for a much less indiscretion.

#### Irish Private Lunatic Asylums.

RESPECTING these institutions, the Inspectors in their Blue-book report that, they continue on the whole to be satisfactorily conducted, some in every respect in the most creditable manner; the visits to them, being one with another, at least monthly.

The aggregate number of patients in them at the close of 1870 amounted to 675—of whom 339 were males, and 299 females; during the year 182 were admitted—82 males, and 100 females—136 were discharged, 70 recovered—26 males, and 44 females, and 40 improved, 20 of either sex, and 26 unimproved—9 males, and 17 females.

The deaths on the daily average (and none of which resulted from accident) under treatment—namely 630—was 42, or at the rate of 6½ per cent., a comparatively low rate of mortality.

#### A Persistent Vaccino-Maniac.

AT a meeting of the Guardians for the Leeds Union, an old woman presented herself and pleaded with piteous earnestness that no further prosecutions might be entered against her son, George Holroyd, on account of his refusal to have his child vaccinated. Using hyperbolic language, she asked that the attempts which had been made to force on the murder of the child might be discontinued. She intimated that her son had done everything he could to meet the heavy burdens imposed upon him, but being now without means, he must go to prison unless the guardians stayed their hands.

The guardians deliberated upon the course that ought to be pursued. The son had been fined five or six times for non-compliance with the law, and it was stated that he has some intention of going to America in order to get beyond the reach of vaccination prosecutions.

The Chairman and all of the members who spoke regarded the case as a very painful one, and admitted that the objections were conscientious; but all, with the exception of Mr. Kenworthy, thought the board could not do otherwise, in simple consistency, and in compliance with duty than put the law in force again if the parties still refused to vaccinate.

The guardians decided on taking proceedings against Holroyd, but the applicant was informed that a month's time would be granted to get the child vaccinated, if there was a disposition to do that.

### Sanity of Criminal Lunatics.

It would appear, from the last report of the Inspectors of Lunatic Asylums, that thirty-one of the total number of persons in confinement (167) are sane. The others labour principally under mania, melancholy, and imbecility.

### Salford Hospital.

At the annual meeting of the managers of the Salford Hospital the Board recorded the munificent donation of £7,000 from Mr. Humphrey Nichols, one of the vice-presidents of the Institution, given without any other stipulation than that it should be invested for the future support and maintenance of the Hospital. This sum, together with former gifts, and recently (1869) the presentation of a number of chief rents, made up an amount of at least £10,000 as contributed to this charity by the repeated acts of generosity of the above-named gentleman.

### Charge against a Medical Practitioner.

LAST week an inquiry took place as to the circumstances connected with the death of Mrs. Sayer. It appeared that Dr. Times had been engaged to attend deceased in her confinement; that he had been called there and found her in a fit; had given some medicine and then left, promising to return in two hours. He did not go back, however, but two hours later than he should have returned sent a letter saying that another medical man had better be called in, as he had to go into the country. Another surgeon, Mr. Jakins, was called, but, owing to his not knowing what medicine had been administered by Dr. Times, he was unable to treat her, and had to send to Dr. Times to inquire. The woman died. In answer to the jury, Dr. Times admitted that it might have been better had he sent another medical man to take his place. The jury returned a verdict that the deceased died from exhaustion in childbirth; but wished to append the following: "The jury consider Dr. Times to blame in leaving the family in expectation of his visit at seven o'clock till half-past nine o'clock without sending any other medical man in such a critical case."

### Charitable Bequests.

MR. JOSEPH JACKSON, of Northumberland Park, Tottenham, has bequeathed £10,000 to establish in Shoreditch a soup kitchen and cottage infirmary, to make up four beds, with paid housekeeper and surgeon. Mr. M. B. Mullins, of Fitzwilliam square, Dublin (in addition to the legacies to medical charities previously mentioned), bequeathed £500 to the Coombe Lying-in Hospital. "R. M. H." has

given £300 to the Halifax New Infirmary. Mr. Samuel Morley, M.P., has contributed £100 towards Mrs. Gladstone's Convalescent Home. The West Kent General Hospital, Maidstone, has received £100 under the will of Mr. T. R. Cutbush. Messrs. Iliff and Mounsey's workmen have subscribed £23 7s. 8d., and the North Eastern Marine Engine Works' workmen £25 12s. 5d., to the Sunderland General Infirmary. Mr. Edward Wigan, of Hibernia Chambers, London Bridge, bequeathed £1,000 to the London Fever Hospital, and £500 each to the London Hospital, King's College Hospital, and Charing Cross Hospital.

### Preserved Vegetables.

LAST session Mr. Buchanan read a paper before the Society of Arts on the preservation of vegetables by a cold, dry process. Having submitted samples to the Admiralty, the following satisfactory report has been received upon them from Mr. Harry Leach:—

1. *As regards present condition.*—All the samples are sound, and in a very good state of preservation.

2. *As regards nutritive properties.*—Quite equal, if not superior, to those of compressed vegetables.

3. *As regards general flavour.*—The spinach, onions, savoy cabbage, and brocoli are exceedingly good, in some respects comparable to vegetables in the fresh state, and the other varieties are fully as good as any average specimen of mixed or compressed vegetables.

4. *As regards facility of cooking.*—No special care or caution appears to be required.

With a view to inaugurate the permissive use of these vegetables in the mercantile marine, it is competent for the Board of Trade (on medical and sanitary grounds) to substitute the word "preserved" for the word "compressed" vegetables (mixed) in the scale of medical stores issued and caused to be published in pursuance of the "Merchant Shipping Act, 1867."

### Our Poor Profession!

OUR "Obituary" gives the name of Samuel H. Cornish—as kindly a spirit as could be conceived, a real friend of the poor, he will be sadly missed by many a family in the locality in which he resided. Twelve months since he was in possession of a large general practice, and the confidence of all with whom he came in contact. A few months later he was a raging madman, confined within the walls of an asylum, and now kind death has come to put an end to his sufferings. This is a sad but true picture, and the subject of it both publicly and privately was a man *sans peur et sans reproche*; yet possessed of a highly sensitive nature, he was charged by a patient in childhood—probably suffering from puerperal mania—with being her murderer! The very thought—although we believe the woman afterwards recovered—preyed so heavily upon his mind, that reason soon gave way, and the poor fellow died, as before-mentioned, on Wednesday last—a helpless maniac. There is no other profession against a member of which such a charge could be made, no other where an innocent man may so easily forfeit his reputation and even his very life! 'Tis a sad, sad reflection.

THE inquiry into the Hampstead Small-pox Hospital is still pending.

WITH respect to the Queen's health, the latest telegram states that although somewhat better, Her Majesty's foot is not yet well enough to allow her to leave her apartments.

CASES of Asiatic cholera having appeared in Constantinople, the officers of the Board of Health have resolved not to give bills of health to masters of vessels about leaving that port.

It is reported that Dr. MacDonald Fox is about to be appointed to a Naval Medical Professorship at Netley Hospital, and that about twenty additional students will be sent by the Admiralty to the Hospital.

WITH improved sanitary arrangements the health of the city of Paris may now be pronounced satisfactory. The week's mortality to Saturday last amounts to 832 deaths, of which 55 are from diarrhoea, 45 from bronchitis, 35 from dysentery, 17 from infantile cholera, and 2 from cholera.

DR. HEADLAND, who is now senior physician to the Charing-cross Hospital, has been elected to the Professorship of Medicine, vacant by the death of Dr. Hyde Salter. Dr. Douglas Powell will succeed Dr. Headland in the chair of *Materia Medica*.

OUR contemporary *The British Medical Journal*, has announced the probable purchase and removal of the Westminster Hospital. Such a rumour at the present season is likely to injure the prospects of this excellent Medical School most seriously, and we have pleasure in giving to it a most unqualified denial. Our contemporary, in its greed for gossip, too frequently gives credence to the most absurd reports, without regard to the institution or persons affected thereby.

THE second fasting case has turned out to be as delusive as the first, but happily that conclusion has not been arrived at at the cost of so unhappy a test. The *Preston Herald* publishes a report on the case supplied by Dr. Marshall, who is in a position to state that the rumour that she has fasted for sixteen months has originated with the public. The girl is confined to bed, and has been for the time specified. She takes a little food, though she can only take a little. The people seem respectable, though poor; and are very much grieved at the publicity which has been given to the case. With the denial of the "fasting," the public interest in the case, of course, is at an end.

THERE has been something of a panic caused by exciting reports of the prevalence of yellow fever in Charleston, South Carolina, and at New York and other ports vessels coming from there are put under strict quarantine. *The Times* says that the Charleston authorities, while admitting yellow fever to exist there, say it is only of a mild type, deny that it will be epidemic, and state that in the aggregate there have not been over thirty-five cases. The quarantine ordered at New York has caused a great dissatisfaction among shipowners; but as a cholera "scare" of large proportions already exists there, the authorities persist in quarantining vessels whenever a chance is offered.

## SCOTLAND.

DR. ALLEYNE NICHOLSON, Lecturer on Natural History, Edinburgh Medical School, has been appointed Professor of Natural History in the University of Toronto.

ANDERSON'S UNIVERSITY, GLASGOW.—As showing the financial prosperity of this institution it may be stated that, while the expenditure for the year amounts to £411, the receipts are £5,223.

## THE PHARMACEUTICAL CONFERENCE.

### ABSTRACTS OF PAPERS READ.

BRIEF REMARKS ON THE BARK OF RHAMNUS FRANGULA, OR BLACK ALDER TREE, A SHRUB OF THE NORTH OF EUROPE (PENTANDRIA MONOGYNIA).

BY H. C. BAILDON, EDINBURGH.

Some time since a gentleman from Holland applied to me to prepare for him a decoction of the *Rhamnus Frangula* bark. The bark he brought with him, having previously found that he could not obtain it in this country. He spoke most enthusiastically of its good properties as a general cathartic, which had proved very beneficial to himself, and which was much used and esteemed by the Medical Profession in Holland. He kindly offered to procure for me a small quantity of the bark. To my surprise, I shortly afterwards received a bale containing nearly a quarter of a cwt., accompanied by the following letter. He writes, "I hope you will find it giving as much benefit generally as I have derived from it personally. The preparation of my Dutch physician was three or four drams of bark to a pint of water boiled down to a half a pint. Two or three tablespoonfuls occasionally night and morning, as an aperient. Than this nothing can be more simple or less injurious, and it does not require increase of dose, but the contrary."

I am aware that this drug is not altogether unknown in this country, though I believe rarely or never used. In the 2nd volume of the first series of the *Pharmaceutical Journal*, page 721, I find a letter signed George Mennie, Plymouth, speaking very favourably of it as a purgative and alterative, and again in the 9th volume, page 537, there is an analysis by M. Benswanger.

I have repeatedly taken the decoction myself, and find the taste not unpleasant, with a slight prussic acid flavour, of which the analysis shows traces. It operates gently as an aperient, without griping, in doses of two or three tablespoonfuls. It appears to me to possess properties which should in many cases render it a valuable substitute for senna—which is often found drastic in its effects, and is nauseous to take—and to be especially suitable for children.

In Holland it must be very plentiful, as it was charged me only at the rate of about 10d. per lb., including cost of carriage. A specimen of the bark and decoction is now upon the table.

### SOLUTIONS.

BY T. B. GROVES, F.C.S.

A short discussion that ensued on the reading, before the Pharmaceutical Conference at Liverpool, of Mr. Rimmington's paper on "The Specific Gravity and the Actual Weight of Certain Volume Measures of Various Liquid Preparations," set me inquiring on the subject of the volume occupied by salts when dissolved in water.

The statement credited to the President by the reporter of the *Pharmaceutical Journal* is to this effect, "That the contents per oz. were coincident with the specific gravity; for instance, lemon juice having a sp. gr. 1.040 would contain 40 grs. of citric acid per oz., and so on, except in such cases as alum and sulphate of soda, where there is much water of crystallisation. In those cases it would be half, or 20 grs. per oz."

Mr. Reynolds followed with the remark, that the same rule applied to sugar in diabetic urine, but properly qualified the assertion by the phrase "roughly speaking."

In the cases of both lemon-juice and urine, the estimation by that method must necessarily be exceedingly rough, as the variations in the proportions of other constituents affecting the specific gravity of the fluids are left out of the question entirely.

Although I have no new experiments to offer, I shall, I think, be doing some service if I recapitulate shortly the facts I have ascertained in the course of my recent reading on this subject. It will, at least, serve to caution some who otherwise would be inclined to place too implicit reliance on the "rough methods," already referred to.

Dalton, during the latter part of his life, occupied himself with the question of solution, and derived from his experiments this supposed law, "that when a body dissolves, it will only increase the volume of the solvent in proportion to the water of crystallisation it contains." His method of research involved the use of two measuring vessels, and pouring backwards and forwards—in fact, was quite incapable of giving accurate results.

This, as well as the want of general applicability of his laws, was pointed out by Hilton, whose volumeno-meter, consisting of a glass flask with a long, narrow, graduated neck, enabled the experimenter to approach more nearly to accuracy of determination. He found that whilst the theory approached correctness in the cases of desiccated sulphate of magnesia and carbonate of soda, it completely broke down in the cases of the naturally anhydrous salts, nitrate of potash, sulphate of potash, &c.

Walker found, to his astonishment, sometimes an expansion, sometimes a contraction of the whole volume of salt and water, according to the nature of the salt employed, and the strength and temperature of the solution. However, he does not appear to have commenced with very clear notions, for after repeatedly employing the terms "bulk" and "volume," he goes on to say, "I next proceeded to determine if the increase of volume had any relation to the specific gravity of the different substances, or if, when a known weight of salt was dissolved in water, the increase of volume was in proportion to the volume, as indicated by the specific gravity, and if so, the salt would dissolve without either expansion or contraction." Did he really expect an ounce of sulphate of magnesia, for instance, to occupy the same space as an ounce of water!

This method involved the use of a volumenometer. The one employed was not so well adapted for the attainment of accurate results as that of some other experimenters, but was, on the whole, far superior to that of Dalton.

Nitrate of potash was the first salt employed in testing the value of his new idea. The specific gravity of nitrate of potash being, according to his determinations, 2.074, one hundred grains of the salt would occupy the space of 48.21 grains of pure water. The calculated specific gravity would therefore be found thus—100 grs. of salt being dissolved in 500 grs. of distilled water—

$$\frac{100+500}{48.21+500} = \frac{600}{548.21} = 1.0944.$$

But the specific gravity ascertained by experiment was 1.1100 showing, according to him, a condensation amounting to 6.22 grain measures.

I certainly cannot deduce this amount from the data given, but make it 7.7 gr. m. However, the principle being established, it becomes possible when the ratio of condensation of a salt is known, to calculate the specific gravity of a solution, within certain limits of accuracy—those limits being defined by temperature and degree of dilution.

The effect of dilution as exemplified in the case of a saturated solution of nitrate of soda is shown to be the following:

If to 430 gr. m. of a saturated solution 60 gr. m. of water be added, the mass will suffer a decrease of volume of 1 gr. m. Sulphate of magnesia behaves in the same manner, and to the same degree. Nitrate of potash suffers a diminution of .5 gr. m., muriate of ammonia .25 gr. m. under the same circumstances.

From a long and laborious paper by Messrs. Playfair and Joule, describing a series of experiments undertaken in order to ascertain whether there really existed any similarity between solid and gaseous combinations, in respect of the law of equal or multiple proportions observed first by Gay-Lussac

in the case of gases—I propose to select those facts only that seem to have some pharmaceutical interest, and are possibly capable of practical application, omitting reference to the theoretical deductions therefrom further than to say that they have since been roughly handled by Professor Marignac, of Geneva, whose criticisms appear to me to well deserve consideration.

The volumenometer employed differed from that used by Holker, in that it had a tubulure in its side for introduction of salt, fitted with a ground-glass stopper. This admitted of the stem being of smaller diameter, and enabled the experiments to be attended with greater accuracy.

Unfortunately, however, the experimenters whilst acknowledging the disturbing effects of temperature and dilution, seem to have adopted no systematic method of procedure as to the one or the other, unless it be true that the particular temperatures and dilutions adopted were selected because the results so obtained accorded best with certain theories sought to be established. This Professor Marignac evidently points at, though he does not actually affirm it.

I may mention the case of sugar as being especially interesting to the pharmacist. The volume occupied by an equivalent of this substance=172 grs., varies according to dilution between 99.00 and 108.06 grm. as follows:—

| Ratio of Sugar and Water. | Temp. | Vol. in gr. m. of 172 gr. Sugar. |
|---------------------------|-------|----------------------------------|
| 1 : 20                    | 60    | 99.00                            |
| 1 : 10                    | 52    | 105.09                           |
| 1 : 1                     | 52    | 107.01                           |
| 3 : 1                     | 52    | 108.06                           |

The temperatures here even are not uniform, I may observe that when the ratio is 1 : 1, the sugar occupies a volume very nearly co-incident with that due to its specific gravity 1.606.

The investigation included the determination of a vast number of specific gravities and solution volumes of salts of every description. In compiling the following table I have selected a few only of special interest, considered pharmaceutically. The specific gravities are, in general, not those of Playfair and Joule, but those obtained by H. Buignet through the use of the Air Volumometer invented by Regnault; and, therefore, I consider, more worthy of acceptance. The term "specific gravity in solution," I employ simply to designate the weight of the solvent in air divided by the space it occupies in the solvent:—

| Name of Salt.              | Sp. Gr. in Air. | Sp. Gr. in Watery Solution. |
|----------------------------|-----------------|-----------------------------|
| Sulphate of Copper.....    | 2.302           | 2.77                        |
| "    Soda.....             | 1.471           | 1.76                        |
| Biborate.....              | 1.692           | 2.085                       |
| Chloride of Calcium.....   | 1.68            | 1.98                        |
| Potash Alum.....           | 1.757           | 2.135                       |
| Ammonia.....               | 1.653           | 2.00                        |
| Carbonate of Soda.....     | 1.463           | 1.58                        |
| Sulphate of Magnesia.....  | 1.675           | 1.96                        |
| "    Iron.....             | 1.902           | 2.22                        |
| Nitrate of Potash.....     | 2.126           | 2.80                        |
| "    Soda.....             | 2.265           | 3.22                        |
| Chloride of Potassium..... | 1.986           | 2.80                        |

Bearing in mind the irregularity that seems to attend all bodies, and mixtures of bodies, on the verge of change of

state, and, therefore, confining oneself to solutions of mean condition, neither extremely strong nor excessively weak, it is possible by means of this table to ascertain beforehand, with tolerable accuracy, the effect of mixing definite quantities of a salt and water, and *vice versa* of determining the proportions of both salt and water necessary to produce a given specific gravity. Thus taking the case of sugar,—what will be the specific gravity of a solution containing equal parts of sugar and water? The volume of the water will, of course, be 1, the volume of the sugar 1·1608th, the total volume being 1·6218. Dividing the total weight = 2 by this, we get the specific gravity = 1·23. According to the table in Watts' "Dictionary," the specific gravity of a solution containing 50 per cent. of sugar is 1·2166 at the temperature 63·5°. Proceeding in the same way with chloride of sodium, we get for a solution containing 20 per cent. of salt the theoretical number 1·159, the experimental number being 1·1511.

Sulphate of magnesia gives for a 30 per cent. solution 1·172 theoretically, 1·1536 experimentally, the temperature in the latter case being 72·4° instead of 60°, which accounts, doubtless, for the comparatively large discrepancy. A solution of specific gravity 1·72 would, at that temperature, contain 33·5 per cent. of salt.

To determine the necessary proportions of salt, or other soluble substance, and water in order to produce a given specific gravity is not quite so simple. In order to avoid having two unknown quantities, we will assume the quantity of water to be known. Let it be 10. It is required to ascertain the quantity of sugar necessary to produce with that amount of water a syrup having the specific gravity 1·20. The specific gravity of the water is, of course, 1·00: the specific gravity in watery solution of sugar 1·608. The symbol *x* represents the unknown quantity we have to ascertain. Then

$$\frac{10}{1} + \frac{x}{1\cdot608} = \frac{10+x}{1\cdot2} = 7\cdot89$$

*i.e.* to produce a syrup of specific gravity 1·20, 7·89 parts of sugar must be added to every 10 parts of water. Such a syrup ought theoretically to contain 44·1 per cent. at 60°. According to the table in Watts' "Dictionary," a syrup of specific gravity 1·2057 at the temperature 63·5 should contain 45 per cent. of cane sugar.

The theoretical considerations involved in the phenomena of solution are so numerous and interesting, that I propose some day to resume the subject I have now merely scratched on the surface, as it were; in which case I will ask again to be permitted to bring the subject before the notice of the Pharmaceutical Conference.

## Literature.

### COLLENETTE'S CHEMICAL TABLES FOR THE USE OF TEACHERS AND STUDENTS.\*

EVIDENTLY resolved to place within easy reach of students a complete and truly royal road by which the goal of success may be reached at a minimum sacrifice of mental and intellectual power, Mr. Collenette has compiled this series of wonderfully concise and extremely simple classification tables, by the aid of which may be unravelled in a few hours the tangled skein of chemical formulae, so as to enable the student of even mediocre intellect to snap his finger at the most "crusty" examiner. These tables are sure to reach the hands of all teachers of chemistry and students of that noble science. Their price is merely a few pence. What a boon!

### LISDOONVARNA SPAS AND SEASIDE PLACES OF CLARE.†

It seems hard that the natural resources of Ireland should fail to be sufficiently appreciated from want of proper enterprise, and this is particularly to be regretted in situations endowed with spas or mineral waters. It is a misfortune

\* Useful Chemical tables for the use of Teachers and Students." By Adolphe Collenette, Teacher of Chemistry, Elizabeth College, Guernsey. London: Baillière, Tindall and Cox.

† "Lisdoonvarna Spas and Seaside Places of Clare." By E. D. Mapother, M.D. Dublin: Fennin and Co.; London: Longmans and Co. 1871. Pp. 47.

both to the physician and to the invalid, for the recommendation of the former loses half its force if his patient has to fear insufficient lodging and a poor *cuisine*. The sulphur and iron spas of Lisdoonvarna, no doubt, deserve a larger *clientelle* than they have yet had, and Dr. Mapother has opportunely brought out a handy little *brochure*, giving from personal experience the necessary information to intending visitors. The pamphlet is divided into four parts:—Historical, chiefly taken from Dr. Rutt's work on the "Mineral Waters of Ireland;" Descriptive, giving an account of the locality, hotel accommodation, &c.; Chemical; and lastly, a sketch of the principal morbid conditions in which the waters are found useful. The sulphur spa has acquired its special repute in chronic scaly skin diseases, particularly psoriasis, in chronic rheumatism, and in gouty affections, while the chalybeate waters are to be recommended in convalescence from exhausting diseases, in ague, protracted diarrhoea, &c.

### THE MEDICAL TEMPERANCE JOURNAL.

OUR quarterly contemporary for October, has appeared, and is up to its usual standard of excellence. The article on cholera, by Dr. Edmunds, which originally appeared in the MEDICAL PRESS, has been copied in full into our contemporary, principally we opine, because the treatment pursued by the author was in direct opposition to the usually adopted methods of alcoholic stimulation. The number also contains various articles original and extracted, and the followers of total abstinence may congratulate themselves upon the possession of so excellent an organ of opinion.

## New Inventions and Preparations.

### RED HEART RUM.

THE great variety in the quality of spirits and wines is frequently a source of difficulty to Medical men, who find it no easy task to secure a stimulant on which they can rely. There is no doubt that the popular impression that rum is the best liquor is to a large extent true, and this spirit would have attained much higher repute had it been possible always to obtain it of the finest quality and of good age. Messrs. White, who are as well known in the rum trade as Martells or Hennessy in the brandy trade, now offer the public the very article that was supplied to the "National Society for the Sick and Wounded in War" during the late contest between France and Germany. We learn from other sources that this was the only rum sent out by the society, and we are also aware that it met with universal approval. We believe that the success of this article is well deserved, inasmuch as it is derived from its excellent quality and great age. Many people who find rum disagree with them and its flavour disagreeable will be surprised if they try this to observe that it has none of the objectionable qualities they attach to rum. Time has sufficed to remove them, and really old rum like this is better than brandy at a much higher price. Hospitals and those who study economy should take the hint.

### LIQUOR ET SAPO CARBONIS DETERGENS.

WE have used Wright's *Liquor Carbonis Detergens* on a large scale in hospital practice, and can recommend it as an efficient preparation. The coal tar-soap has been lately improved, it is all that can be desired. We recommend it, not only in those skin diseases in which it has been so much used, but as an excellent soap for the medical man himself, who so often requires a purifying agent of the kind.

### POROPLASTIC SPLINTS.

MR. JONATHAN HUTCHINSON has taken a good deal of trouble in the investigation of substances suitable for splints, and we have had the opportunity of examining those he has introduced at the London Hospital. Of these

**Mr. Cocking's Poroplastic Sheet** is one of the most valuable. It is light, porous, flexible, plastic, and economical—is made in all required strengths and sizes. It consists of a felted substance in sheets, is plastic when softened by heat, and becomes rigid when cold, and can be re-softened any number of times without injury; it is rapidly and easily manipulated, the most difficult splint requiring but a few minutes to complete—is very well adapted for metal attachments, and is thus a very valuable material for interrupted splints. There is no glue used in its application, and the gums with which it is stiffened are quite harmless.

It is used in the following manner:—Select the sheet of the most suitable strength, and, having fitted and cut a paper pattern, put it on the sheet, and mark the shape clearly on it. Cut it accurately, and then soften the piece or splint in hot water: the time it will take to soften will depend on the substance of the splint, but a minute will be about the average. Then, having cooled your hands in cold water, mould the splint as near the required shape as you can. Whilst it is still warm (but not inconveniently so for the patient), place it on the part, previously protected by a linen, cotton, or wadding covering, and press gently till the splint has set. Should any portion not fit exactly, the whole splint need not be re-softened, but apply a hot-water sponge, and soften it locally where required. The splint thus prepared and fitted will retain its shape, and will be cool and light, and cause little, if any, inconvenience to the patient.

We have no hesitation in recommending it as the best and most convenient splint. The country practitioner will find it a special boon. Mr. Cocking deserves further the thanks of many, inasmuch as he supplies it to hospitals almost at cost price.

**THAMES SHIPPING INSPECTION COMMITTEE.**

A MEETING of the above committee called together by Dr. Buchanan, in view of a Cholera Epidemic, for the more efficient inspection of the shipping of the Thames, was held at Guildhall, on Monday, September 11th, at which representatives were present from most of the boards or vestries of districts abutting on the Thames. The chair was taken by G. S. Pedler, Esq., C.C.

The hon. secretary (Dr. C. Meymott Tidy), stated that he had communicated the resolution of the committee to the Admiralty, and that they were willing to lend the *Rhin* to the committee as a hospital ship for cholera patients in the event of its being required for that purpose. It would be possible to bring her down to Gravesend in about twelve hours. It was agreed to accept the *Rhin*, and the committee empowered the Mayor of Gravesend to telegraph for the vessel to be sent, immediately a case of cholera makes its appearance. The Admiralty requiring that the committee should insure the *Rhin* against fire in the sum of £2,500, a resolution was passed agreeing to these terms.

Dr. Tidy reported that he had received a letter from the Secretary of the Metropolitan Asylum District Board, to say that patients suffering from cholera, for whom immediate provision must be made, may be received on board the hospital ship *Dreadnought*.

A letter was read from the Vestry Clerk of Rotherhithe, to say that the vestry declined to name a representative to act on the committee, inasmuch as they were of opinion that any expenses incurred in the more thorough inspection of shipping on the river, should be borne by the country at large, and not by the river side authorities only.

It was reported to the committee that as yet no case of cholera had made its appearance on the Thames. A discussion took place respecting the appointment of a special medical officer, to carry out the inspection of shipping along the whole river and in the docks. It was agreed that such an appointment was most advisable, and that it be referred to the sub-committee to further such an appointment, and to report to the committee at their next meeting.

**NOTICES TO CORRESPONDENTS.**

**NEW READING CASE.**

In consequence of the postal restrictions as to stitching the Journals, improved reading cases with twenty-six strings to hold one volume can now be obtained through any bookseller in town or country, price 2s. 6d. The advantages to subscribers are, that each number when received by post has but to be slipped into the cord, no stitching or pinning being required. The Journal is kept flat for reading, and each volume complete for reference. The same portfolio can be used for successive volumes where desired.

**WASP STINGS.**—A Correspondent writes, that he has found the most simple and the best remedy for the sting of wasps and bees is to apply to the parts affected common salt, moistened with a little water; and even in a case where a person has accidentally swallowed a wasp in a draught of any kind of liquor, and been stung by it in the throat, the alarming symptoms that ensue may be almost immediately relieved by swallowing repeated doses of salt and water.

**ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.**—The Treasurer begs to acknowledge the receipt of £1 for the year 1870-71 from Dr. Lynch, Loughrea.

**RULES AND REGULATIONS FOR THE POST-MORTEM HOUSE, PARISH OF MARYLEBONE.**

To the Editor of "The Medical Press and Circular."

Sir,—Reading over the rules of the vestry of Marylebone, I find that the Surgeon who desires to make a post-mortem examination of a body, is bound to undertake to convey the body to the post-mortem house enclosed in a shell or coffin, and remove it at his own expense. Now, Sir, I should like to know why the Surgeon is to be the undertaker, and pay expenses on such an occasion? Should not the friends of a corpse be liable for all this. As to making a post-mortem, it is not done in my branch of the profession, whatever opinion I may form on the examination, is another thing as performed by a Surgeon for my inspection. I, nevertheless, consider the laws of the vestry an error, and that the relations or friends of the deceased, should direct an undertaker to do what is required as far as conveyance and removal of a corpse at their expense. Yours truly,

A PHYSICIAN.

UNDER AUTHORITY OF THE

## IRISH MEDICAL ASSOCIATION.

### CLAREMORRIS UNION.

#### INCREASE OF SALARY.

MR. JAMES JORDAN, pursuant to notice, proposed an increase in the salary of Dr. Davis, medical officer of Ballyhaunis dispensary district. He said he had very little to say beyond what was embodied in the recommendation of the committee of management of the Ballyhaunis dispensary district, who considered it right to entertain his claim for an increase of salary, founded on his long services, extent of his populous district, and the large and increasing amount of duty he has to perform, and at a time when it is more expensive than formerly to keep both horses and servants. For the many years Dr. Davis has been in charge of the dispensary he has discharged his duty with credit to himself and benefit to the public; and, from his close attention, had saved the district a great deal, for since his appointment he never asked them to pay a penny for a substitute, and whenever he required one he paid his substitute himself. Under these circumstances he proposed that Dr. Davis's salary be increased from £100 to £125 per annum, and he hoped it would be unanimously agreed to.

Mr. Michael O'Grady seconded the motion of Mr. Jordan.

The Chairman said he should again do the unpopular thing, and object to the proposed increase, however much he should regret differing from so many of the doctor's friends. He would endorse every word of what has been said in favour of Dr. Davis, but he should recollect there was apparently a very bad time coming. The prospects of the harvest were not very encouraging, and very many of the struggling ratepayers have enough to do, even in prosperous seasons, to meet their engagements, and those people require consideration; increase of taxation will affect them more than any other class. The medical expenses appear to be increasing ahead. In 1866 the salaries of medical officers was supposed to be fixed at—Ballyhaunis, £100; Ballindine, £75; Claremorris, £75; and the workhouse £50. Since then these salaries have been increased considerably—the other two dispensaries to £100 each and the workhouse £80. This was only the first move at another increase. Now Dr. Davis's extensive district is given as a grounds of increase, and no doubt there will be cause shown for the other districts. We will be told Ballindine is a backward place—no resident proprietors—no private practice, and an increase is therefore necessary—the same in the other cases. In view of such expenditure on the poor ratepayers, he could not agree with the proposition.

Captain Sheffield fully agreed with the observations of Sir Robert. Propositions to increase the expense in the other districts are sure to follow.

Mr. J. E. Treston said as the Ballyhaunis people wish to tax themselves, he did not see why they would not allow them; he would therefore support the motion to increase Dr. Davis's salary.

The board then divided, when there appeared for the motion—12; against—6.

### OMAGH DISPENSARY COMMITTEE.

THE meeting was for the purpose of appointing a medical officer for the Omagh East Dispensary District, in the room of Dr. A. C. Walker, resigned.

It was proposed and seconded "That the election be postponed for three weeks." It was proposed as an amendment, and seconded, "That the election do now proceed."

The amendment was carried by a majority of sixteen to eleven.

It was then proposed and seconded, "That Dr. D. J. Rutherford be elected medical officer for the Eastern Division of the Omagh Dispensary District.

A poll was taken, when there appeared for the motion sixteen votes, against nine.

The Chairman declared Dr. Rutherford duly elected—there was no other candidate.

The following protest was handed in by Lieut.-Colonel Ellis: "We protest against the election of Dr. D. J. Rutherford to the Carrickmore Dispensary until the circumstances under which he left Newtown Stewart Dispensary be fully entered into and explained.

### NAAS UNION.

#### ABUSE OF RED TICKETS.

MAJOR BURROWES asked the Clerk to produce the Act of Parliament referring to the issuing of dispensary visiting tickets, as it appeared from a report which he read in the *Leinster Express* of last week's proceedings, that a farmer, holding fifty acres of land in the district of North Naas, had applied for and obtained one from a member of the Dispensary Committee. He (Major Burrowes) was anxious to know if men in such comfortable circumstances were legally entitled to relief of that kind or not.

The Clerk, in reply, said there was no law bearing upon that subject. A dispensary committee, he said, had the power of cancelling a ticket if it were found to be illegally issued; at the same time it was the privilege of any other member of the Committee to issue a ticket to the same party on the following week, and in such cases the doctor had no discretion but to attend the parties for whom said ticket was passed, or subject himself to a very serious responsibility.

#### DOCTORS' FEES.

The question of doctors' fees charged to parties in humble circumstances in this country as compared with England and Scotland having been discussed, the Board were unanimously of opinion that a guinea for the first visit, notwithstanding that two complimentary visits were subsequently paid, was entirely too high.

A member of the Board stated that he had occasion while sojourning in Scotland, to call in a physician to attend a member of his family, who had taken ill, and on asking the doctor what his charge would be, he was not a little surprised to hear that it was only 5s. On a more recent occasion a tenant of his, an industrious poor man, became sick; the doctor, it appeared, had only three miles to travel to see him; having paid him six visits, the poor man, on his recovery, asked to be furnished with the doctor's bill. The account was accordingly supplied, from

which it appeared he was charged six pounds, or one pound for each visit. The poor man represented the matter to him (the speaker), stating that he could not possibly pay that large sum, and asked his advice as to what he should do. He told the man to pay the doctor the £2, which he thought would be sufficient, and to hold out the hope to the doctor that he would give him another £1 after the harvest. The speaker, in conclusion, said he thought a guinea a visit was entirely too much to charge a poor farmer.

The Board fully concurred with the speaker's views on the subject.

Major Burrowes thought the law relating to dispensary relief very defective, and that there should be a fixed qualification (say a man not holding more than ten acres of land) to entitle a person to dispensary medical relief.

---

### GALWAY UNION.

#### SUPERANNUATION OF DR. CONSIDINE.

MR MARTYN—Now that Dr. Considine is superannuated, and as we all know him, and also know how his services have been appreciated by the poor, I think it is but fair we should give him that compensation which the law allows us—namely, two-thirds of his salary. He is very delicate, and it is the least we might give him for the rest of his life.

Chairman—How much will that be, Mr. Martyn?

Mr. Martyn—His salary is £90 a year, and two-thirds of that will be £60.

Chairman—Do any of the members present object to Mr. Martyn's proposition?

Mr. O'Flaherty—I beg to second the proposition, and I do not think there will be a dissentient voice in the room.

There being no opposition, the motion was declared carried.

The Board soon after rose.

---

### CARRICK-ON-SUIR.

IN a communication from the Commissioners they acknowledged receipt of minutes of proceedings of the Board of Guardians of Carrick-on-Suir of the 26th ult., containing an entry to the effect that the Committee of Management of the Carrick-on-Suir Dispensary districts had granted leave of absence to Dr. Fitzgerald, the medical officer, and appointed Dr. O'Ryan his temporary substitute, and also a resolution requesting to be informed whether a committee of management of a dispensary district can grant the medical officer of such district leave of absence, without first having obtained the sanction of the Board of Guardians. In reply, the Commissioners drew attention to the provisions of Article XXII. of the Dispensary Regulations on the subject, according to which the appointment of a temporary substitute is vested in the committee of management; the amount of remuneration, if any, to be paid to the substitute being a matter to be determined by the Guardians, subject to the approval of the Commissioners.

---

### SERIOUS CHARGE BY A MEDICAL OFFICER.

AT a meeting of the Guardians of the Killarney Union, on Wednesday, the chairman read the following correspondence;—

“Miltown, 2nd September, 1871.

“My Lord,—I regret very much being obliged to bring under your notice the following case:—I was last week in attendance in her confinement on Catherine Quirk, the wife of a labourer living about two miles from Miltown. On last Saturday, after two days' attendance, I was preparing to deliver her, when Father Bat. O'Connor came to give her the last sacraments. The case was an urgent one,

and admitted of no delay, as the life of the child depended on immediate delivery, and the safety of the mother would be risked by delay, it being a case of powerless labour, with contracted pelvis. On my return to the house, I was told that Father Bat. ordered them not to allow me to deliver her, but to let her work enough that night. I then told them that the child would most certainly be dead and the mother's life risked. I was sent for next morning to deliver her, which I did with the forceps, but the child had died in the meantime, and the mother had a narrow escape of *post-partum* hemorrhage. Now, I am prepared to prove that, in my opinion, the child's life would have been saved if Father Bat. had allowed me to deliver her the evening before, and I respectfully submit that it was not Father Bat.'s place to interfere with, and obstruct me in, the discharge of my duty, and in the most trying and difficult position in which a medical man can be placed. If the poor woman had died I would rather not say what may be the charge that could be preferred against this gentleman. If your lordship will not exercise your authority in this case, and prevent a recurrence of such conduct, I must claim the protection of the Commissioners, both for myself and the poor of my district, against the injurious interference of Father Bat.—I remain, my lord, your most obedient servant,

“JAMES HANIFIN.

“To the Right Rev. Dr. Moriarty.”

That letter did not state whether the person Dr. Hanifin was in attendance upon had got a red ticket, or whether she was a private patient.

Mr. Murphy said it was a red ticket case.

Chairman—It is important to know that. The next document is a letter from Father Bartholomew O'Connor to the chairman of the Killarney Union:—

“Miltown, Co. Kerry, Sept. 12, 1871.

“My dear Sir,—I enclose you a letter, which has been written and forwarded by Dr. Hanifin, Medical Officer of the Miltown Dispensary, to my bishop, and with the letter I forward my own declaration, and that of Anne Moriarty, the midwife, and I hope that those documents will be placed by you before the Board of Guardians, and forwarded to the Poor-law Commissioners, in hope that they may be pleased to grant a sworn inquiry, as I am aware they will, into the charges contained in Dr. Hanifin's letter to the bishop against me. I also call for a sworn inquiry into Dr. Hanifin's treatment of Catherine Quirk; and as a proof that there is good reason for granting this inquiry, I beg to place some of the particulars bearing on the case before the Commissioners. Dr. Hanifin left the sick woman at about three o'clock on Saturday, and did not return until eleven o'clock in the forenoon of the same day, when he had to be sent for, and after working for two hours, as the midwife describes, striving to deliver her, he returned home, a distance of about two miles; he leaves the woman to work her way until morning—words attributed by Dr. Hanifin to Father Bat. in his letter to the bishop. And again, after the lapse of about eight hours, he was obliged to be sent for again; and after this gross neglect on his part, he charges me with being the cause of the loss of life on the occasion—a grave charge. May I ask you, if I am out of order, or the necessary forms in calling for the sworn inquiry, to have the defect supplied by some friendly member of the board.—I remain, with great respect, yours faithfully,

“B. O'CONNOR.”

Mr. Gallwey moved that the documents be forwarded to the Miltown Dispensary Committee, accompanied by a request from the board that they receive the Committee's immediate attention.

Agreed to.

---

### SLIGO BOARD OF GUARDIANS.

#### CARNEY DISPENSARY DISTRICT.

The Commissioners wrote to say that the committee of management of the Carney dispensary district having ap-

pointed Dr. Thomas Popham as one of the medical officers of the district, they directed that he should be supplied with the usual documents.

The commissioners, in a letter to Mr. Kerrigan, as honorary secretary to the committee, sanctioned the appointment of Dr. Popham, at £100 per annum.

A letter was read from the commissioners sanctioning the appointment of Mrs. Mary Anne Leonard as midwife for the Carney dispensary district, at a salary of £20 per annum.

#### MIDWIFERY CASES.

A letter was read from the commissioners in reference to the report of the master read on last day, relating to two midwifery cases recently admitted to the workhouse hospital, in which he stated that on sending for the medical officer to attend one of these cases, that gentleman informed him that the midwife should first be sent for; in reference thereto the commissioners said it was the duty of the master, when he became aware that an inmate was in labour, to send for the medical officer, whose duty it was to attend and see the case was properly cared for to its termination.

The commissioners also wrote in reference to Mrs. Deignan's application for £1 for attending two cases of labour, in accordance with the directions of Dr. Powell, medical officer. In reference also to the midwife's statement in regard to one of the cases that the woman was so ill that she would not have recovered only for her (the midwife's) assistance—that about two hours after the woman was delivered of a still-born child—the commissioners called on the guardians to hand over this statement to the medical officer for the purpose of enabling him to state whether he ascertained, on visiting the case, that it was one of natural labour, unattended with danger, and whether he gave directions to the midwife that should anything out of the ordinary course of nature arise he should be immediately sent for.

The doctor's attention was called to those letters.

Dr. Powell said he saw that there was no risk at all in either case, and all a doctor would have to do was to sit by and look on. The doctor promised to supply a written report on the subject.

Subsequently it was ascertained that Mrs. Deignan, the midwife, was not entitled to any extra fee for attendance on those cases in the workhouse, as they were cases from her own district, and as Mrs. Johnston had previously attended on three of her cases. The board directed that Mrs. Deignan should attend the workhouse when the other midwife was incapacitated, and that she should get no extra fees.

The following letter was next read, as Dr. Powell's report in reference to the late reported cases of midwifery which occurred in the workhouse:—

Sligo Workhouse, September 11, 1871.

"DEAR SIR,—In compliance with the commissioners' desire that I should report on the midwife's statement regarding 'Susan Baker,' I beg to say that when sent for by the master I came and examined the woman, and concluded it was a case of ordinary labour, merely requiring the services of the midwife. She had not been sent for previously as was usual, and acted on up to this, so I directed the master to have her sent for forthwith. As to the history of the nurse and all she did and prevented, I consider the whole surcharged for the purpose of obtaining remuneration. I may now state that in every case before and after the calling in of the dispensary midwife, the woman, or women, who had acted previously to her—the head nurse and the assistant nurse—all had directions, in case of any difficulty or sign of danger, to have the medical officer sent for, who then took charge of the case and watched it to its termination. This was a standing order which has hitherto worked well, and this case (my house being only a short distance from the workhouse), I told the night watchman to bring me word from the nurse early in the morning how the woman got on, with the view of again visiting her if necessary. He did

so—the answer being, 'Woman well; at two o'clock, child still-born.' The other patient, 'Jane Furey,' with whom the same course was adopted, being also a case of ordinary labour, did well, and the child is still living.—I have the honour to be, &c.,

"EDWARD POWELL, M.D."

This letter was considered very satisfactory, and it was ordered to be placed on the minutes.

The board shortly after adjourned.

#### MOUNTMELICK UNION.

##### IMPORTANT TO POOR-LAW MEDICAL OFFICERS AND THEIR SUBSTITUTES.

THE Clerk said the next business to come before the Board was Dr. Rice's application for payment of £24 for discharging the duties of medical officer of the workhouse, and of the Mountmellick dispensary district during the recent illness of Dr. Clarke. In the month of June, he said, Dr. Clarke reported to the board that he was in delicate health, and he applied for leave of absence. It was then proposed by Mr. M'Evoy, seconded by Mr. Gaze, and resolved unanimously—"That Dr. Clarke be allowed one month's leave of absence, as he states that he is in delicate health, and that Dr. Rice be appointed to discharge the duties at the workhouse at a salary of £2 per week, one-half the expense to be borne by Dr. Clarke, and the other half by this board." At a special meeting of the Mountmellick dispensary committee held on the 23rd of June, it was proposed by Mr. Millner, J.P., and seconded by Mr. Edward Murphy—"That Dr. Clarke get one month's leave of absence in consequence of ill-health, and that Dr. Rice be appointed to act as his substitute at the usual payment of £2 per week, to be paid out of the rates of the union." At a meeting of the board of guardians held subsequently, it was proposed by Mr. Millner, seconded by Mr. Kirkpatrick, and resolved unanimously—"That this board approve of the above resolution of the Mountmellick dispensary committee granting Dr. Clarke a month's leave of absence in consequence of ill-health, and appointing Dr. Rice to discharge the duties in his absence at a salary of £2 per week." In reference to this resolution a letter was received from the Commissioners sanctioning the proposed arrangement. At the end of the month Dr. Clarke applied for extension of leave, when it was proposed by Mr. Kinsella, seconded by Mr. Cullen, and carried by a majority of ten to eight—"That Dr. Clarke get the leave applied for, but without pay during the time of his absence." I know, continued Mr. Goodbody, that it was intended by the board that Dr. Rice should not be paid by the board, and I was so strongly of that impression on that very evening I wrote word to that effect to Dr. Clarke. I did not observe the mistake till Monday when I was writing out the minutes.

Mr. Cullen—My idea was that Dr. Rice should be paid. The labourer is worthy of his hire, but the man who is idle should not be paid for work he did not perform.

Chairman—With reference to the month's leave of absence, all that was fixed by the board and sanctioned by the Commissioners. In my opinion, if there is anything to be discussed it is with reference to the fortnight's extension.

The Clerk read the following resolution, which had been proposed by Mr. Cullen, seconded by Mr. Cobbe, and passed at the meeting of the board on the 2nd of May, 1868—"That in all cases when officers apply for leave of absence they must state at the same time whether they propose to pay their substitutes themselves, or if they expect the board to do so; in the latter case a fortnight's notice is to be given to each member of the board before payment is voted."

Mr. Cobbe—If the board go contrary to that resolution there is no use in passing resolutions at all.

Chairman—The Commissioners have led Dr. Clarke and everybody else to suppose that everything as regards the month was settled. The extension of time is what must come under the consideration of the board, and I hope gentlemen will confine themselves to that.

The Chairman read the 22nd article of the Commissioners' rules, pointing out the course to be followed whenever a medical officer is incapacitated by illness, or otherwise from attending his duties, and which has been very frequently copied into these reports.

Dr. Tabuteau said if it was agreed that everything as regarded the first month's leave was settled, inasmuch as the fortnight's extension of leave was granted under the very same circumstances, he did not see what argument could be raised against paying Dr. Clarke, as well as his substitute.

Mr. Cobbe said that though the resolution was put, the votes were taken under a different intention altogether. The intention was that Dr. Clarke should pay his own substitute.

The Chairman, with the view of shortening the discussion, said he would put it to the meeting whether the extension of leave should be taken into consideration, or the whole period.

Mr. T. Cobbe thought that as far as the first month was concerned that was decided by the board, and there was no use losing time over it.

Mr. Cobbe.—The only question as to that is this, did the board act right or not in voting payment without the fortnight's notice required by the resolution of May, 1868?

Chairman—I don't think we can review the acts of that board.

Major Carden—Certainly not, when the Commissioners have sanctioned what was done.

Dr. Edge—Then let it be distinctly understood that the first month is quite disposed of.

Mr. Cullen—I cannot consent to that. We have a right to discuss the entire question, if there is any force at all in the resolution of the 2nd of May, 1868. At one time a gentleman stated here that a medical officer of this union had a pimple, and that was what induced him to ask for leave. I can't be positive whether it was true or not, but this resolution was passed to counteract applications for leave, and to prevent a man with a pimple applying for leave, and to have his substitute paid out of the rates. Why should that resolution not have its full force! I do not wish to waive the right of any guardian to discuss the whole question. If Dr. Clarke made an application to the board in the right way, and respected the rules of the board, no matter what feelings any guardian may have towards him, the matter would be fully discussed according to that resolution; and it could not then be said by any one that he selected a particular day to make his application.

Dr. Edge—It is neither Dr. Clarke nor this board you are punishing, but the man who did the duty. There was a man doing the duty for a whole month, and surely because there was not a very full board on that day you would not fall back on that resolution of the year 1868 to frustrate the payment of a just claim.

Mr. Cullen—At first I said the labourer was worthy of his hire; but, inasmuch as Dr. Clarke did not comply with the resolution of the board—

Chairman—Before we go any further, I wish to let the meeting know clearly what it is in my opinion we are called upon to discuss. A resolution was passed on the 23rd of June by this board—It was proposed by Mr. M'Evoy, seconded by Mr. Gaze, and passed unanimously—“That Dr. Clarke be allowed one month's leave of absence, as he states that he is in delicate health, and that Dr. Rice be appointed to discharge the duties at the workhouse at a salary of £2 per week, one half the expense to be borne by Dr. Clarke, and the other half by this board.” That resolution passed here. At a special

meeting of the dispensary committee they passed this resolution—“That Dr. Clarke get one month's leave of absence in consequence of ill-health, and that Dr. Rice be appointed to act as his substitute at the usual payment of £2 per week, to be paid out of the rates of the union.” You see that resolution was passed at the dispensary meeting, the committee agreeing to give Dr. Clarke one month's leave and to pay Dr. Rice, which resolution was confirmed by this board, and the Commissioners have approved of it. No resolution contrary to that has been proposed since, and I hold it is perfectly out of order to discuss anything so far as the month is concerned.

Mr. Cullen—I have as good a right to repudiate that resolution as the board had to repudiate the resolution passed in May, 1868. At least nineteen-twentieths of the hard-working ratepayers disapprove of the resolution, and feel that there was an advantage taken of them. There was great fault found with me for calling this outdoor relief. I say it is nothing more than a gratuity to hand over this money to a medical officer and pay his substitute besides.

Chairman—The board passed a resolution—I was not here that day—granting a month's leave, and undertook to pay his substitute. No attempt has been made to rescind that, and in good faith of the board Dr. Clarke absents himself.

Mr. Cullen—Allow me to put a case in point.

Chairman—As to the fortnight you may, but we must restrict ourselves to that. We cannot go back upon what has already been decided.

Mr. Cullen—I am quite willing now that for the month the allowance should be paid, but not for the fortnight.

Dr. Edge—Then if you propose that:

Mr. Cullen—I do.

Dr. Edge—I will second your proposition.

Chairman—Then is it decided that Dr. Rice shall be paid?

There seemed to be no dissent.

Mr. Millner said he would propose that Dr. Rice be paid the full amount, £24, by the board.

Mr. Balfour seconded the proposition.

Chairman—I take that as an amendment on your resolution.

Mr. Cullen—You cannot put it as an amendment; you must put it as an original resolution.

Chairman—Dr. Rice very properly brings his claim against the Board for £24, if the board are willing to discharge his claim. Dr. Rice was the servant of the board, not the servant of Dr. Clark. Was Dr. Clarke given the fortnight's extension of leave?

Clerk—Yes, without pay, but I believe the intention was without pay to Dr. Rice. The words were put in “without pay to Dr. Clarke.”

Mr. Kirkpatrick—I propose that Dr. Rice be paid the sum of £24 applied for by him for discharging the duties of Medical Officer during the recent illness of Dr. Clarke; and that £12 of the above sum be deducted from the salary of Dr. Clarke.

Major Carden—I oppose it. It is a very hard thing to expect any officer, a Medical Officer, in case of illness should have to pay a substitute. If we appoint a substitute we should pay him (hear, hear.) People will get ill some time; illness will happen to everybody, and it is very hard he should be called on to pay his substitute. For the month at all events the substitute should be paid. After that, perhaps, one might expect him to pay his substitute.

The votes were then taken with the following result:—

For the amendment—14.

For the resolution—14.

The votes being equal, the Chairman voted in favour of the amendment, which was then declared carried.

# The Medical Press & Circular.

## INTRODUCTORY LECTURE

DELIVERED AT THE

### LONDON HOSPITAL MEDICAL COLLEGE.

By W. J. LITTLE, M.D.,

Formerly Senior Physician to the Hospital, and Professor of Medicine at the College.

GENTLEMEN,—This is the first occasion of a past member of the staff appearing before the class of the London Hospital for the purpose of giving the Introductory Lecture. This fact itself is significant of a belief in the existence of an identity of interest and of feeling in the present staff and school and the past members of the staff. Every thing, indeed, that has interested the past, that interests the present, or may interest or affect the welfare of the future body of officers or pupils, constitutes our common bond of union and fellowship as members of the London Hospital and its Medical College, and is a gratifying result of the past history and working of the Hospital. In perhaps too readily, on this occasion, responding to the summons of the Council, we may be permitted to say, in consonance with habit, with great justice in our case, to dwell upon the mistrust we entertain lest we should fail to do justice to its wishes. In deciding to appear in the present capacity, we believe a sense of duty has preponderated over some other considerations; perhaps, however, the thought so well expressed by the Poet Laureate,

"How dull it is to pause, to make an end,  
To rust unburnished, not to shine in use!"

may not have been without its weight, forgetting at the moment the precept of Horace,

"— Versate diu, quid ferre recusant,  
Quid valeant humeri."

Revolving in the mind the relationship of the past and the present stirs the thought as to the future of the Hospital and of its youngest members in particular, and of the medical profession itself as it may be influenced by them. We are tempted—"Laudator temporis acti"—to look back to the moment when, forty-three years ago, we for the first time sat

upon the benches of the old anatomical theatre, listening to the introductory lecture of that day, delivered by Mr. Headington, at the commencement of his annual course of anatomical lectures. We were then freshly entered, like so many of you, gentlemen, this day. The first thought, and that a painful one, is of how few of the then young faces, soon to become familiar ones, which glowed with intelligent emotion at the eloquence of a Headington, are now to be seen. One at least is here—Mr. Curling, who by his persistent exertions in the cause of practical and scientific surgery, his researches in pathology, by his readiness to adopt all novelties that promise to be beneficial to humanity, has shown the present generation of students how the advantages of the London Hospital can best be utilised. He can recall, we doubt not, the glories of the discoveries and improvements of the previous forty years, as related to us in language unsurpassed for accuracy and for freedom from exaggeration, in language pure in diction, noted for clearness, quietness, and perspicuity—language, indeed, to which we, unhappily, can make no approach. Mr. Headington was an accomplished and sound surgeon, who had more the appearance of the learned and well-bred physician of that day. He early handed over the operating knife to the able hands of Mr. Luke, then his assistant-surgeon. The greater number of my hearers may never have heard the name of Headington: in fact, he lived, he practised, and died in a part of London—Spitalfields—then wealthy and of comparatively fashionable resort. It has been a loss to surgery that he was not addicted to spreading his fame by any writings; but it is a sufficient proof of the distinguished hold he possessed of the respect and affection of his colleagues and pupils, that he was one of the few whose bust and portrait adorn the building in which we are now assembled.

Headington made known to us the triumphs of Hunter, Pott, Jenner, Baillie, Haller and Bichat, Cavendish and Lavoisier, Dalton and Davy. The theories of Stahl, Cullen, Brown, and Broussais were then first brought to our knowledge; we learnt then how great had been the progress of the medical art during the previous forty years.

It may on this occasion be not merely a matter of personal interest to ourselves and any contemporaries—medical antiquaries as it were—to note briefly some of the men whose merits were eulogised by Headington, and who almost constituted in themselves stand-points in medicine and surgery, and the allied branches of knowledge, during the forty years

preceding Mr. Headington's address. It is too easy perhaps to fall into the historic vein.

The beginning of the period we are considering may be roughly stated as having been ushered in by two important events in the world's history, the American war of Independence and the great French Revolution. The consequent agitation of men's minds, as well as the acquisition of a new power supplementary to man's individual physical force, in the application of steam to the purposes of mankind in branches of the arts into which it had not been previously introduced, were probably all momenta aiding the progress of man in the departments of science and learning embraced by the cultivator of medicine. In this country eminent medical men worked on in our thoroughly English way, little aided by state assistance, except in the happy circumstance of the purchase by Government of Hunter's museum. Hunter's fame needed not even the preservation of his museum to render it "*vere perennius*." It cannot be doubted that Hunter's career had exercised considerable influence on the progress both of English and foreign medicine during the first thirty years of this century. But in France in particular, at the beginning of the present century, a great impulse was given to medical studies by the appointment of a Government commission on the reorganisation of the medical schools of Paris, Montpellier, and Strasburg. The names of many of the ablest physicians and philosophers of that country appeared upon that commission. In Germany, also, the younger University of Berlin, fostered by the wide confidence in the future of German science, was beginning to emulate the reputation of Leyden, Göttingen, Upsal, Halle, and Vienna.

The beneficial influence of a man's labours, and especially of so great a man as John Hunter, being often greatest after his disappearance from the scene of his labours, was illustrated in this instance. Anatomy, Surgery, and Physiology were all powerfully impelled onwards during the epoch we are considering—say from 1790 to 1830—by his unexampled successful career. Headington in his lecture laid great stress upon Hunter's operation of ligaturing the artery above the aneurism as even then one of the greatest practical improvements of his age.

Mr. Headington might well expatiate on the merits of Jenner as a man of science, and as one having a higher claim to profound admiration as a benefactor to mankind in general. Bacon has said, "There are short methods for men of genius," but it might perhaps with propriety be also said that there are *new* methods for men of genius; their characteristic is that they do not walk in beaten roads, and are not deterred from following it through unfrequented paths. The originality of Jenner's mind and his accuracy of observation are shown by the universal reception and practice of vaccination, by the brightest luminaries of our profession in all the civilised parts of the earth.

The fair way of judging of the merits of an invention is, as Sir Humphrey Davy said, "by the operation of the discovery upon civilised and social life; and in this respect Jenner"—a pupil of John Hunter, be it remembered—"stands almost alone, having discovered the means of subduing a positive evil, and having secured a benefit not only for all the inhabitants of the earth that have existed since his time, but for their most remote posterity, gaining for his name the most enviable kind of immortality—that arising from the gratitude and blessing of the reflecting portion of his fellow-creatures in all countries, and which will be more estimated in proportion as men estimate more correctly the nature of the truest glory—that of saving the lives of myriads of mankind."

We cannot let pass this occasion of stigmatising the conduct of government which, after a statue, the first erected in this country to the memory of this great man and physician, was inaugurated with considerable ceremony in Trafalgar square—the ceremony being graced by the presence of one of the most benevolent and enlightened men of the time, the late Prince Consort, and other distinguished personages, as well as by the authorities of the Royal College of Physicians—caused it to be removed from its public and noteworthy position from amongst the statues of men famed for their military glory, to a comparatively obscure walk in Kensington gardens. Surely even the shades of Sir John Franklyn and Lord Clyde in Waterloo place must blush at the injustice inflicted on the memory and services of Jenner. However much we may all admire military virtues, the discredit done to the memory of Jenner and to the medical profession, by the removal of his statue from a prominent and unrivalled situation in the metropolis to a subordinate one, indicates a preference for the glory attendant

on the destruction of human life rather than for that attendant on its preservation.

This was the period also when the names of Black, Cavendish, Priestly, Dalton, Scheele and Berzelius, Lavoisier and Gay Lussac, Berthollet, and Davy were in men's minds. You will learn from your excellent teacher Dr. Letheby and his coadjutor Dr. Tidy, to how great an extent the atomic theory, morphology, and chemistry in general, have since been modified by Davy, Mitscherlich, Faraday, Tyndall and others. Perhaps one of the proudest things ever said of a great chemist has been said of Berthollet, who died in 1825—"He was remarkable for a high degree of candour, renouncing his opinions with the greatest readiness whenever the progress of science was opposed to them, and this even in old age!" a point of character worthy of all imitation.

Headington did not leave untouched the researches of Cuvier and his assistants, of whom Brogniart was the principal. To Cuvier's genius, belonging entirely to the period we are considering, we owe the great elucidation of the then mysterious subject of extinct animals. Hunter had been one of the earliest, if not the earliest, who showed how many thousands of years appeared necessary to account for the terrestrial changes associated with fossil remains. And yet in Headington's time Geology was only in the condition of sturdy youth. A generation of able men, most prominent among whom has been a fellow member of our profession, Owen, has been successfully employed in its advancement.

Headington overflowed with admiration of two most notable physiologists who are now rarely mentioned, but whose works, together with those of Hunter, formed the foundation of English physiology of the period we are considering—Haller and Bichât. Of the sterling worth of Von Haller's Physiology I cannot do better than quote a naïf remark made half a century after Haller's death by Rudolphi in the introduction to his own work on physiology, viz.: "That if any author of a book on physiology were asked whose work on that subject was the best, the inquirer could not complain if the author named his own. But if inquiries were made whose was the second best, all would reply 'Haller's.'" That work, however, on physiology which appears to all authors on the same subject the second best, is doubtless, as Rudolphi remarks, the best.

Some modern pathologists do scant justice to the physicians of the last century. We may be permitted to say a word of commendation for another of Headington's great men—we allude to Cullen. It is doubtful whether any better *vade mecum* in nosology than that of Cullen has since been published, although needing adaptation to the present time.

Of the remaining physicians lauded by Headington, Baillie's works show the accuracy and coolness of his judgment, his minuteness of observation, and his acuteness in referring effects to their true causes.

Brown and his speculations, in an attempt to supplant the theory and practice of Cullen, produced a profound sensation at the beginning of this century. Brunonianism, as they were called, since justly reviled, may after all, by its intense opposition to the antiphlogistic treatment of the period, have contributed to the reaction of later years in favour of the use of supporting treatment in disease.

On the other hand, Broussais' researches, which in Headington's day were on the tongue of every physician, referred all forms of pathological disturbance to gastro-enteritis. His severe antiphlogistic regimen and medicinal treatment contributed much to prolong the reign of most extensive blood-letting by leeches, and even of venesection. The student of to-day would be aghast at the application of fifty leeches daily for many days until the patient risked dying, or did die, from loss of blood, and at the string of twenty patients waiting their turns to be bled in the arm,—a weekly event in some practitioners' surgeries.

Bichât—"This was a man!" as Shakespeare says—Bichât, one of Headington's worthies, who has been named the physiological physician *par excellence*, has left an imperishable name in anatomy and pathology. He wrote his celebrated works, "Researches on Life and Death," and his "General Anatomy," before the age of thirty—"Decies repetitum placebit"—an encouragement to you who are about to become engaged in the arduous pursuits of medicine. His career shows that it is not merely the inspired genius and power of observation of the poet, the artist, or the orator that may distinguish its possessor at an age when the majority of men are only beginning to find their position in the world, but that natural gifts, employed with industry and energy in the wards of a large hospital, in

the deadhouse, and in the laboratory, may yield one or more of you an undying reputation before others have awoke to the consciousness of a laudable career being really open to them.

Bichât was the first to study thoroughly the relations of the membranes and structures of the body to one another, and to subject them to such an analysis and generalisation as the state of chemistry and microscopy then permitted. He rendered a great service to pathology and practical medicine in first distinctly showing that the closest similarity existed between the phenomena of disease in each particular membrane or structure, wherever situated; that, for example, given the knowledge of certain changes which occur in and upon a serous membrane when inflamed—say, the peritoneum—the physician was first taught by Bichât that similar changes take place in, and other situations where a serous surface is found, the phenomena being modified only by the peculiarities of each organ which is invested by a serous membrane. With similar results he investigated the cellular and mucous membranes, the fibrous and other structures; and, whilst shedding a new effulgent light upon a minuter anatomy than had yet been taught, he prepared the way for much of the progress of morbid anatomy and the improved diagnosis of disease, and even for the minute microscopical investigation of the tissues, which has characterised French, German, and English medicine in later years.

We cannot forbear mentioning at this moment a former distinguished physician and professor here, Dr. Pereira, whose bust also adorns this museum. He became attached to the London Hospital several years after our pupil days, but we had the good fortune to be attracted by his reputation as a teacher of *materia medica* and chemistry to his lecture-room at the then existing Aldersgate Dispensary. Pereira was a warm expounder of many of the memorable discoveries of Bichât. We confess, however, to not having taken in the best part of his persistent efforts to make us understand the differences between Bichât's animal sensibility, Bichât's animal contractility, organic sensibility, insensible contractility, and lastly his sensible organic contractility—terms now happily for you relegated for the most part to the realm where there is neither pleasure nor pain; whither also have gone the vitalistic theories of Stahl, the theories which constituted Brunonianism, and many other theories and hypotheses.

"All these, up-whirl'd aloft  
Fly o'er the backside of the world far off  
Into a limbo large and broad, since call'd  
The Paradise of Fools."

We all owe much to Pereira for the thoroughness and excellence with which he taught and the example he instilled. He was the first lecturer whom we saw who was accustomed to use diagrams to illustrate his lectures.

Mr. Headington did ample justice to contemporary surgeons in the persons of Dupuytren, Larrey, Cline, Cooper, and others.

During the last forty years numerous circumstances have tended to encourage increased knowledge in medicine. Possibly we may be disposed to disregard the cautions necessary in mistaking the *propter* for the *post*, but it appears nevertheless true that the last forty years, like the former period of similar duration, was ushered in by stirring changes in the world at large. One of these was the reform movement about 1830, of which certainly one consequence has been that of a greater attention to and diffusion of education, a direct result of the accelerated movement of ideas of that exciting period, and a great extension of periodical and higher class of literature within and without our profession. During this period the application of steam to land travel, and especially to transatlantic and other distant maritime locomotion, followed, as it soon has been, by electric telegraphy, have all contributed to bring peoples of different countries to mutual inter-communication of ideas, opinions, and discoveries, and have stimulated improvement in our art during the last forty years, equally with other arts, professions, and pursuits. An indubitable cause of progress in medicine was the establishment of the University of London soon after 1830.

The present owes much to the able and enlightened men, Lord Brougham, Mr. Grote, Dr. Billing, Dr. Roget, and others whom, during that great "march of intellect," the Sovereign honoured by appointing them members of the first senate of the university destined for the encouragement of learning, science, and humanity. Another notable circumstance, creditable alike to Dr. Billing, and to the London Hospital which it is permissible on this occasion to mention, is, that the first

course of clinical lectures on medicine delivered in this metropolis was delivered at the London Hospital by him. Previously to his time isolated irregular bedside observations, both in surgery and medicine, will naturally have flowed from the lips of able men, such as Cheselden, Baillie, Abernethy, the Blizard, and others whose names have already been mentioned to day; any one, however, who witnessed the monotonous silent hospital round of the old-fashioned physician of Headington's time will bear us out that the example of thorough clinical teaching was sorely needed in those days. It may now be truly said of Dr. Billing, as was said of Morgagni in the language of Virgil.

Nec tarda senectus  
Debilitat vires animi, mutatque vigorem.

Anybody whose memory can carry him back to the state of medical affairs in 1830 will agree that whatever influence was exercised upon English medicine from abroad was mainly derived from the schools of Holland, Italy, and France. So considerably was the study of medicine fostered by the varying French governments—the Directory, the Republic, the Consulate, and the Empire—acting under the inspiration of the world-renowned *savans* of the period, that by far the greater part of that which came to us from the Continent proceeded from French sources. This was particularly the case during the fifteen years following the peace of 1815, which opened Paris to our medical and surgical predecessors, with the medical and surgical treasures accumulated by Dupuytren, Larrey, Corvisart, Laennec, and a host of other distinguished men.

Since 1830 the most superficial student of medicine cannot fail to have noticed the influence of German anatomical, physiological, and pathological discoveries, as well as of practical, medical, and surgical improvements, upon English medicine. We have only to contrast the physiology taught by Burdach and Johannes Muller with that contained in the text-books of Richerand and Bostock, then most used; and it may be doubted whether any greater surprise could be experienced than that entertained by the students who passed from England to Germany early in the period since Headington's lecture, on their witnessing the enormous advance made in Germany in anatomy and physiology as compared with this country. Schwann, Henle, Remak, and a crowd of other eager students, under the fostering hand of Muller, were preparing the way for the discoveries in microscopical research, applied to anatomy and physiology, which have since rendered their names famous.

The opening of the London University College, followed by that of King's College, under a galaxy of teachers, foremost among whom were Grant, Sharpey, Conolly, and Carswell, rapidly accelerated productive inquiry in the highest departments of medical science in this country.

Charles Bell, Marshall Hall, and Kiernan may here be mentioned; these have been succeeded by Carpenter, so long professor of physiology in this College; Owen, and Quekett a worthy alumnus of the London Hospital, Huxley and Flower, and others who have followed in the footsteps of Hunter and Cuvier. Some of these have attained (*i.e.*, Cruveilhier) to the highest rank in the world of science, contributing to raise again the fame of England to the elevation it deserved to occupy. During the period we are considering the names of Majendie, Flourens, Cruveilhier, Louis, Longet, and Bernard, Ricard, Trousseau, Nélaton rise to our memory amongst the most distinguished of our nearest neighbours, and have become "household words." The English student has become acquainted with the labours of Reichart, Gräfe, Bisehoff, Virchow, Liebig, Kolliker, Schönbein, Schroeder Van der Kolk, Wagner, Rokitansky, Skoda, and others, which speak to the activity of the Continental branch of the Teutonic races. The works of Physick, the Warrens, Mott, Brown-Séquard, Pancoast, Bane, Van Buren, Jackson, and others, prove that medicine and the allied sciences have been successfully transplanted and have borne good fruit beyond the Atlantic. All these, and more, form "stars of several magnitudes—some goodly and great ones, that move in orbs of their own—others small and scarce visible; but all are stars, and no star is without some light." In fine, the almost innumerable contributors who have illumined our paths during the last forty years might be termed, in all humility and piety before the Father of Light and First Grand Cause, the "milky way" of medicine.

It would be presumption to select, even were it "*sine ira et studio*" any names from amongst our own fellow-practi-

tioners. It will be considered excusable in the case of London Hospital men.

If we pass to the actual improvements in our art effected during the last forty years, almost the first in chronological order, and one of the most frequent and successful application, is that of subcutaneous tenotomy by Stromeyer. Subcutaneous tenotomy of the members paved the way for Stromeyer's suggestion of conjunctive operation for the cure of strabismus, and its successful performance by Dieffenbach, for which these two renowned surgeons received the prize of the French Academy of Medicine. Dieffenbach was also the able reviver and improver of plastic surgery. Subcutaneous osteotomy for the cure of ankylosis of the largest joint, the knee, has been performed, for the first time in this country and at this hospital, after a novel method, by a nearest relative of our own, Louis Stromeyer Little, a former junior surgeon of this hospital, who has also successively performed several other extensive osteotomical operations. Subcutaneous tenotomy laid the foundation for subcutaneous surgery in general, and it has probably not been without its influence upon the most conservative of all surgery, viz., the modern practice of closing all wounds as soon as possible, excluding the air as perfectly as possible, and leaving the part as much at rest as possible, with the help of improved mechanical apparatus where required: a state of things the very reverse in some respects of ancient practice.

"*Si parva licet componere magnis,*" the knife used in tenotomy is, it is true, a very small one. We are unable to reconcile the danger announced by Mr. Lister, of carrying germs of disease into the body, say with a new cutting instrument, or one perfectly clean in the ordinary sense in which the operator speaks of his instrument, with the fact that we have ourselves performed thousands of divisions of tendons subcutaneously, without in a single instance witnessing a particle of pus secreted from the puncture: even when subcutaneous incisions of considerable depth and range have been made. Surely, if the danger of introducing pus germs or putrefaction germs into the living structures with the knife existed, some one instance of suppuration after subcutaneous tenotomy should have occurred in our experience.

We confess to a belief that in the treatment of wounds and compound fractures, as elsewhere in our art, other things being equal, the proportion of recoveries and the freedom from accidental complication correspond with the amount of skill and care with which the treatment is carried out by the individual practitioner. It is not surprising, therefore, that we read of less favourable results from antiseptic treatment of wounds by others than those obtained by Mr. Lister; nevertheless, the Profession and humanity at large owe much to him for the zeal and ability with which he has propagated his ideas. It is a gain to all—to the doctor as well as to the patient—to arrest putrefaction of the decaying tissues and discharged fluids.

Coeval with the discovery of subcutaneous anatomy by Stromeyer was that of lithotripsy by Civiale and Heurteloup. We have since had the discovery of iridectomy by Græfe; ovariectomy, the idea of which has been traced back to the Hunters, we are told by Dr. Tyler Smith has been successfully performed by Clay, and repeated by Spencer Wells and others, tracheotomy and excision of joints have become operations of established repute. The success of subperiosteal resection of bones, or parts of bones, followed by reproduction, enables us to understand the wonderful specimens of new or reproduced bones, contained in museums, thanks to Nature's respect for the periosteum. In the improvements in ophthalmology several London Hospital surgeons and pupils, past and present—Critchett, Wordsworth, Hutchinson, Streatfield, and Cowper—have borne parts. In fine, every department of physiology, pathology, and practice, has been diligently investigated anew, root and branch, with the result of undoubted alleviation of suffering, and the saving of human life.

As if the catalogue of previously known diseases were insufficient to engage all the knowledge and resources of our art, many others—severe and destructive, alas! and numerous—have struck our shores since 1830—Asiatic cholera and diphtheria; the trichina spiralis has probably also been imported. New arts, with all their value, exhibit the painful drawback of inducing previously unknown diseases—poisoning by phosphorus, and other agents employed in trade processes.

In past ages, happily, some diseases have taken their departure—plague, leprosy, malignant agues, for example—having left but feeble reminders of them to urge us to con-

tinue to labour in hygienic national self-preservation. Let us hope that some existing diseases may also disappear. The occurrence of malignant pustule, and its singular mode of propagation by insect carriers to man, as shown by Budd, and the communication of glanders to the human subject—horrid and fatal diseases—and the undoubted spread of several other epizootic diseases of various kinds to man, possibly equilibrated by their spread from man to animals, or their simultaneous occurrence in man and animals, appear until the last forty years to have little arrested the attention of medical observers.

Pyæmia, septicæmia; phlebitis, thrombosis, embolism; colloid, amyloid, fatty mucous, and lardaceous, gummatous, and cholesterine deposits and degenerations, have been brought to our knowledge by the labours of modern pathologists, and the relation of malignant to non-malignant been better studied.

Other diseases and changes which formerly escaped recognition in the dead-house have been brought to light. We were familiar in our pupil days with inflammatory dropsy; but it was reserved to Dr. Bright, of Guy's, to discover the disease of the kidney, of which albumen in the urine followed by anæmia, dropsy, and uræmia are the symptoms. Guy's may be proud that Addison, taught by Bright's success, discovered the singular and sometimes rapidly destructive diseased condition which is accompanied with bronzed skin, and changes in the supra-renal capsules.

The use of cold-water applications in disease, commenced by Currie, carried to abuse by Priesnitz and his followers, has of late years been largely extended to the relief of inflammation. Esmarch has acquired a world-wide reputation by his advocacy of cold-water irrigation and ice, as well as by many other valuable contributions to surgery.

An important addition to our resources, that of systematic thermometry as a means of diagnosis in inflammations and fevers, has been made during the period of which we are speaking, and may be mentioned here. We owe to a member of our staff, Dr. Woodman, an able translation of Wunderlich's treatise on this subject. It is due to a former senior physician of this hospital, Dr. Cobb, under whom we had the pleasure to officiate on occasion of the first invasion of cholera in 1831, at Newcastle-on-Tyne, to state that he, and others beside himself, employed at that time the thermometer to measure the fatal tendency to death. Esmarch, who is as well known for his accuracy of observation as for his skill and boldness as an operator, has recently favoured us with his latest observation on ice-application to joints and acute inflammation of bone. He states that he can demonstrate the therapeutic propagation of cold to the interior of the living bone, and a reduction thereby of temperature in the internal part amounting to 10 deg. Cent.: a fact which, when considered in connexion with the daily palpable beneficial effect of ice to external parts, enables the physician to understand the efficacy of cold applications to the trunk in inflammations and hæmorrhage. Truly Æsop might have said of the physicians that we blow hot and cold with one breath, for as a Profession we still think highly of warm applications in similar cases. You, gentlemen, will have to watch the practice of your physicians and surgeons, and learn how and when to employ either one or the other.

In 1830 auscultation and percussion were just struggling into notice in this country. In this hospital Dr. T. Davies, fresh from the schools of Montpellier and Paris, laboured most effectively to disseminate a correct knowledge of heart and lung disease. It is pleasant to add, that our former pupil and colleague, Dr. Herbert Davies, has since worthily represented his excellent father in the branch of inquiry and practice he had made his own.

Improvements such as have been supplied by new instruments and modes of diagnosis—to say nothing of the fertile additions made by the chemists to the testing of the secretions, and excretions, keeping pace with their own discoveries in organic and animal chemistry—have been numerous since 1830. Much has been gained by the spectral analysis of blood and other fluids.

In thus hastily, but yet perhaps tediously, summarising the improvements in medical practice during the last forty years, we may be permitted to advert to the successive changes in theory and practice we have witnessed. We have seen, as a ready stated, antiphlogistic treatment and venesection lauded, then disregarded, now unduly disparaged.

We have seen pathology and therapeutics based on the solid changes found after death, taking the place of the remains of

the old humoral pathology, and of the neuro-pathology which had become predominant after the anatomy of the nervous system was better comprehended. As soon as there appeared fewer realms in wholesale morbid anatomy to be conquered—minute microscopical investigations, coming to the front, simultaneously with much discovery on the part of physicians and chemists, conspicuously headed by Andral and Gavarret, as to the chemical constitution of the blood and other fluids—the coarser morbid anatomy, and its great and profitable influence upon practice, gave way in a great degree to the more recent humoral pathology; and the tendency again rose of regarding all diseased actions as mainly the consequence of blood disease. One good result was the detection of the frequency of anæmia, which has contributed much to lessen the hasty resort to venesection. It is singular to how great extent the modern humoral pathology appears already to have had its innings. At present, not denying the influence of blood changes—it being in fact undeniable that blood modifications, as regards quantity and quality, dependent as the blood unavoidably is upon what we breathe, eat, drink, and avoid—pathologists are again inclining to a neuro-pathology, to this extent—that the determination of the part or organ in which a lesion shall be manifested depends upon the spot of the central parts of the nervous system with which that organ stands in relation by its nerves, organic and animal. In fact the brain, spinal cord, and sympathetic, may be regarded as a measurer, indicator, and resenter of blood impoverishment and other change. The central organs of the nervous system, being the largest receivers of blood—being as largely ramified throughout the frame as the sanguiferous system—presiding by their various nerves over the organic, incident, excitomotor, sensitive, and voluntary-motor functions—appear to be destined to feel first all morbid impressions and deficiencies, and to indicate and to resent, by means of localised distant phenomena, the injury they experience from altered blood. Of the component parts of the central nervous system, the spinal cord and its prolongation into the brain appear to lay claim to the greatest agency in the production of diseases, *i.e.*, morbid phenomena in the functions and organs of the economy at large. We would not say that the blood is diseased in certain states, but that the blood becomes the carrier to the centres of the nervous system of altered quantity and quality of material, instead of proper materials, such as are necessary to the physical building and maintenance of a healthy organism, including that of the maintenance of the physical structure of the organs of the nervous system itself, and also of its dynamic capacities. As an instance of the revived neuro-pathology, Bärensprung attributes herpes labialis to disturbance of the ganglia, or the posterior roots of spinal nerves from which trophic nerves spring. The supposed dependence of diabetes upon disease at the base of the brain is another instance of similar neuro-pathological explanation of disease.

We find Dr. Day following Mitchell of Philadelphia in attributing the visible phenomena of rheumatism to lesion of spinal marrow, a cerebro-spinal meningitis. Billing always taught that rheumatism was neuritis. Our experience of spinal disease tends to confirm such views. There again exists at the present time an increasing tendency of physiological pathologists to acknowledge the identity of nerve force with the electric, as suggested by the history of the torpedo, the *gymnotus electricus*, the action of frog muscle upon the galvanometer in Du Bois Raymond's experiments, and those of C. B. Ratcliffe.

The discovery of previously unnoticed forms of paralysis in contraction and deformities, and the association of peculiar forms of paralysis with insanity has largely engaged attention. Dr. Ramskill and Dr. Hughlings Jackson, members of our staff, have distinguished themselves in the path of nervous disease. In connection with nerve disease, we are reminded of the recent discoveries regarding the constitutional action of syphilis upon many internal organs, notably the nervous system. It is difficult to state what tissue escapes the action of syphilis. If ability, industry, and perseverance will settle in our time many still knotty points as to syphilis, it may fall to the lot of our senior surgeon, Mr. Jonathan Hutchinson, who has already done so much for the elucidation of this and other diseases. The symmetry of many diseases—for instance, certain skin diseases—appears explicable, most satisfactorily by referring one determining link in the causation to be in the nervous centres.

It has been long observed that pathology and therapeutics have always been shaped by the immediately preceding discoveries in anatomy, physiology, chemistry, and natural

philosophy; and it has always seemed to us that the progress effected in these sciences, which approach nearer to exact sciences than the art of treating diseases, accounts better for the fluctuations in medical practice, without the necessity of invoking the aid of changes in the type or character of diseases.

It may help in the elucidation of this subject of change of type in disease to mention that, forty years ago, when one surgeon was apparently destroying the sufferer from fractured ribs by venesection, antimonial and laxative medicines, and low diet, laudably dreading inflammation, another was curing the same and the concomitant pain by a bandage, moderate diet, and a sedative at bedtime, and the worst class of cases of compound fracture, in a greater proportion than his contemporaries, by assiduous personal looking into everything, and by very free use for his day of meat, wine, and porter. One physician was dosing all his patients for weeks with C. c. J. (calomel and jalap), with mist. cretæ cath.; another salivated all his urgent cases; while a third was more eclectic and painstaking, and pulled his patients through by looking more to their wants and complaints, and their diet, using exceptional bleedings only, and relieving suffering freely with opium. These divergencies in practice at this hospital, and the opportunities of comparing different modes of treatment, bore fruit in the after practice of the pupils. The same process was doubtless carried on, more or less, at other hospitals throughout the kingdom. A more critical observation in later times, aided by improved knowledge of the human frame both in health and disease, has contributed more than the pleasantries of Montesquieu, Le Sage, J. J. Rousseau, or Butler, to bring about greater correspondence in the treatment of disease.

The words of Schiller in the mouth of Mephistopheles—

“Der Geist der Medicin ist leicht zu fassen;  
Ihn durchstudirt die Gross' und kleine Welt,  
Um es am Ende geh'n zu lassen,  
Wie's Gott gefällt.”

were not inappropriate in his day.

In no disease has there been a greater and more beneficial change than in the intimate knowledge and treatment of different forms of tubercular disease; in this work another of our staff, Dr. Andrew Clark, has borne an honourable share.

We would fain have dwelt on some of the more obvious improvements in military surgery, the opportunity for which was furnished by the Schleswig-Holstein war which has produced Stromeyer's “Maxims of Military Surgery;” by the Crimean episode, by the Italian war, by the enormous war between North and South America, and by the recent campaigns in which first Prussia and Austria, and next Prussia and France, were engaged. It is incontestible that the American struggle was redundant of examples to Europe of the manner in which modern appliances should be used to mitigate human suffering. It may be doubted, however, whether greater additions have been made to military surgery than through the comparatively small wars of Schleswig-Holstein. This may be regarded as an illustration that small wars, like small hospitals, when presided over by men like Stromeyer are more profitable to science than wars of greater devastation and human suffering, and the monster hospitals, despite all their modern improvements, which large wars necessitate.

And now, gentlemen, what are the prospects of our art during the next forty years, a long time to look forward to in the history of our profession, relatively a much longer period in the individual history of each of you, during which period you will constitute, we trust, some of the principal actors? Thanks for the almost lightning rapidity with which every discovery is flashed throughout the civilised globe, the time has long passed when the power of effecting and recording improvements was confined to the few.

He would be a bold lecturer who should undertake to forecast events. One statement may safely be ventured upon, that the rising generation, encouraged by the successes of the last forty years, assisted by former labours and the accumulated instruments of observation, with the materials—the book of nature—ever at hand, has advantages not exceeded, if even possessed, by former generations.

There are but too many departments of medical practice needing earnest study. You have to support the noble unselfish work of the prevention of disease, inaugurated by Hippocrates (see his writings on “The Airs and Waters”), nobly followed out by Jenner, Blane, and a host of laborious and benevolent men. There are still diseases and stages of

disease in the presence of which the ablest practitioner is disposed to sink his head upon his breast—in certain fevers, in tetanus, in cancer, in algide cholera, in hydrophobia, in advanced consumption.

Are we too sanguine when we express a hope that before another forty years shall have elapsed some of the diseases last named shall become more tractable to our art? Incredulity would be, as elsewhere, the parent of idleness, and is only a cloak for ignorance. The improvements witnessed during the last forty years justify ardent hopes of the future. Cabanis says, "good practitioners in medicine are all men full of confidence in their art. This confidence is perhaps in some respects as much the cause as the result of their success."

With great respect for a deservedly honoured former President of the Royal College of Physicians, we are not of opinion that purgatives will augment the chances of recovery in malignant cholera, as they do in English diarrhoea and cholera; these appear to us to be totally distinct diseases. We have not lost faith in the idea that, when the normal function of the stomach and the lacteals are in abeyance, science is likely to discover the proper medicinal agents and liquids, and the proper mode and channel of introducing them into the circulating system in just the proper quantity necessary to sustain life. Each visitation of the disease enables us to learn something more of its nature. At the last visitation our assistant-physician, Dr. Sutton, proved that fatal cholera in one respect resembles, as was suspected, other epidemic diseases in being more fatal to those whose viscera were previously unsound.

Happily periodical and general literature teems now with sanitary exhortations. Parliament and the great outside public have begun seriously to believe that the prevention of disease is a possibility, and is not the mere laceration of enthusiastic and visionary medical men. The teaching of preventive medicine was for a long period a purely unselfish act, though too often regarded as an officious one. There were long ago exceptional individuals outside our profession who recognised the value of its labours in this direction, and eminently aided its progress; of these the name of Chadwick deserves to be mentioned. Now that salaried officers are appointed to superintend and carry out the teachings of the medical philosopher, no lack of candidates for the office exists (some beyond the ranks of our profession), and sanitary science cannot henceforth fail to be more widely beneficial. It will rest with the rising generation of physicians, by their continued zeal in the elucidation of obscure points in the avoidable causation of disease, to take care that the seed of future honours, sown broadcast by the medical man, unrequited except by his own conscience and the admiration of his professional brethren, shall not be appropriated by other professions which have not borne the heat and burden of the day. May not our profession justly claim that the future health minister of the three kingdoms shall be selected from the ranks of medicine, as a tribute to its past labours in the cause, and an acknowledgment that the education of the physician can alone insure thorough comprehension of the evils sanitary science undertakes to combat.

As in the mineral world of both hemispheres, the choicest stores of the precious metals are found in remote or in the least accessible places, so the rich peculiar lodes of pathological knowledge, and mines of medical and surgical experience, of the London Hospital, were formerly only accessible from the west through the difficult "cañons" of Newgate street and Cheapside, or the obstructed passes of Smithfield and White-chapel markets. The medical student of the present day, if he have not the advantage of the ubiquitous and everywhere faring steambot, or the Great Union Pacific Railway, to carry him to his El Dorado, may, thanks to the Holborn Viaduct, the removal of two ancient markets, better police arrangements for the removal of street obstructions, supplemented by underground railways and tramways, be enabled to reach the site of his labours with a speed and saving of time undreamt of a generation ago.

You will receive, gentlemen, in this College and Hospital such aid in your studies from each of a fresh generation of lecturers, beginning with anatomy, as the veteran and justly popular John Adams, now one of your consulting surgeons, or the well-known Dr. Letheby, has been accustomed to give to his particular class; the Committee and Governors of the Hospital have most liberally spared no means to render the Hospital and College worthy of their objects, second in all essentials to none in the metropolis. The charity of the public distributed within these walls supports over five

hundred inmates, looking to you, gentlemen, when sufficiently advanced in your studies, to assist the numerous staff in the performance of its hospital duties, asking you meanwhile to remember the hospital motto—

"Nihil humanum a me alienum puto."

Here you will see wholesale what cannot be seen in every hospital—we were about to say, in our admiration of the London Hospital, in any other hospital; we may say, as regards some classes of objects, that the London Hospital stands unrivalled. Situated close to the river and the docks, and surrounded by factories of almost every description, and railways travelling in several directions, some terminating in it, this large hospital of the Tower Hamlets may be described as receiving tribute from sea and land, of objects of misery seeking relief and cure at the hands of its medical and surgical staff. In order to profit by all the sad material of misery, rich in instruction to the student, you must not suffer your eyes to wander over it either listlessly or too much absorbed in the painful reflections so much suffering cannot fail to produce. Besides listening to formal lectures and clinical teaching, you must see well, with the unassisted, the microscopical, and your mind's eye, the things continually presented to you.

"Segnius irritant animos demissa per aures,  
Quam quæ sunt oculis subjecta fidelibus, et quæ  
Ipse sibi tradit spectator."

Never be content with superficial observation; whatever you undertake to inquire into, look below the surface of things, employ all your senses in your investigations, avail yourselves of all the modes of inquiry taught you. In the present day it is useless to be merely a good auscultator, well up in the chemistry of the urine, familiar with the names and varieties of the excretions, skilful at anatomy and the setting of fractures; no you must apply *thoroughly* all your ability. In fact, the English word *thorough* should be your watchword and guide in all your doings.

Gentlemen, much has been handed over to you by your predecessors, much is therefore expected of you, and that promptly, if you would emulate the generation now passing away. Schiller says

"Wo viel Licht ist, ist starker Schatten."

Your first duty is so to profit by the instruction here provided that you may make capable members of an active, honourable, and useful profession. Many of you may hereafter be wholly engrossed in worthily performing the offices of the medical man—*Non omnia possunt omnes*: few of you who may not be able to hand the torch of science to your successors the brighter for the labours you have employed in tending it. Some of you, it will be expected, will, as London Hospital men, leave behind you names as honoured as those of Blizard, Headington, Pereira, and Billing, and others whose busts adorn this place.

As Schiller says also of Science and her followers—

"Einem ist sie die hohe, die himmlische  
Göttin, dem andern  
Einem tüchtige Kuh, die ihn mit  
Butter versorgt."

Let it be your resolve, whilst seeking an honourable existence through your profession, to cultivate it more in the spirit of the first of these lines than in that of the second. This alone can make you satisfied with it.

## ABSTRACTS OF INTRODUCTORY LECTURES

DELIVERED AT THE

OPENING OF THE MEDICAL SESSION,  
1871-72.

WESTMINSTER HOSPITAL.

OCT. 2, 1871.

DR. BASHAM commenced by observing that it might be to the advantage of those now entering the profession to have placed before them the relative position assigned to medicine and surgery among the other arts and sciences. These words were so constantly employed almost as convertible terms, that it

was expedient to give such a definition as would enable the student to comprehend clearly the position held by medicine among other branches of human inquiry.

The word science comprehended investigations into the powers and properties of matter—inorganic as well as organic—the mutual action of forces and masses—the laws of matter, statical and dynamical.

The term art was applied to everything which was the product of the mental or manual skill of the individual.

Science, properly so called, was either deductive or inductive. The first comprised the exact sciences—mathematics. The second inductive included the natural sciences, or physics; and the object of these was a knowledge of the laws of the material world.

The natural sciences were then classified, and the necessity for a knowledge of them to the student and practitioner of medicine was insisted on. It was shown that all these branches of knowledge rested on correct and trained observation.

The arts were then enumerated. They severally included whatever was effected or produced by the mental conception or the manual skill, or both, of individual minds, art producing combinations or effects which could not happen or exist except through the conceptions of individual intelligence.

The highest efforts or products of art might be accomplished without any specific knowledge of natural science. But when art was aided by natural science the result was greater perfection.

But if science was not absolutely necessary to the existence of art, how different was it with the practice of medicine. There was not one of the natural sciences, some knowledge of which was not imperatively required in medicine.

The aim and scope of medicine as an art were shown to be the preservation of the body in health, and the freeing it from those evils and disorders which neglect of the laws which govern and minister to life most surely entailed.

These could only be accomplished by a thorough knowledge of the nature and force of those laws. The first essential was a minute and searching knowledge of structure, both human and comparative; the second, a knowledge of the functions of the several organs. On a thorough knowledge of anatomy and physiology the whole fabric of medicine rested.

It was shown that the vital forces were examples of the economy of the natural laws of the material world. Not only did these vital forces work in accordance with the physical laws, but they were evolved in strict obedience to, and dependence on, those laws. The functions of the heart, of the lungs, the action of the muscles, the structure of the eye and ear, were illustrations of the adaptability of structure and function to the laws of the natural world.

The position of medicine up to this point was that of a science strictly inductive.

The causes of disturbed functions were then glanced at: a definition of health was offered as a starting point of comparison with the earliest manifestations of deranged or diseased structure or function. The scope of general pathology was thus mentioned as consisting of an inquiry into all the conditions, causes, symptoms, and results of disordered health, whether among individuals or among the mass. Allusion was made to epidemics.

Medicine, as an art, had, from its earliest records, recognised the prevalence at times of particular types of disease. In tracing the origin, the mode of propagation, and the means of restraining epidemic forms of disease, was recognised as one of the most important duties of the profession. Although little success had yet attended efforts to avert such epidemics as cholera or scarlet fever, yet over one fearful scourge the genius of Jenner had triumphed, and victory, complete and undoubted, had been the result of the contest between vaccination and small-pox.

There could be no higher aim for any science than to stamp out the causes which favour the propagation of disease of whatever kind among the community.

To investigate the causes of the unhealthiness of any given locality, to trace the development of disease to the co-operation of vice and ignorance, to propose means for the sanitary welfare of large and populous places, was the paramount duty of the profession. But to accomplish this required a mind specially trained, one accustomed to exact and patient observation, skilled in all the collateral branches of medicine. A chemist, a physiological one, conversant with the morbid agencies of air defective in purity, with its sources of contamination, with the influence of soil and drainage on animal health, with the qualities of water and its impurities, some knowledge of con-

structive art should also be added. The influence of particular kinds of labour on health, and the several diseases peculiar to special trades and occupations, also required attention. To perform these duties required a high-class medical education, to which should be added sound judgment, a tact in dealing with the prejudice and ignorance of people, and a power to persuade by reasoning rather than of dictating by authority.

After some remarks on the limited means of generalising on the action of remedies, and establishing any definite law as to the certainty and exactitude of their action, moral probability, or at most moral certainty, was all that could be arrived at.

The lecturer proceeded to sum up the attributes of medicine both as a science and an art.

It was a science in relation to the means and sources from whence it was derived, for it was built up of many, if not all, the other natural sciences.

It was an art, however, in its exercise, and its value was proportioned to the scientific training, the tact, and judgment of the individual practising it.

It was an art which, for extent and variety of knowledge possessed by its more distinguished members, was not exceeded, scarcely equalled, by any. Its utility was universal, for it was with advantage and benefit exercised in every region of the world, alike useful to all nations, peoples, or creeds.

Medicine was the science of observation applied to the investigation of everything which related to the health of man, individually or socially. It was based on a thorough knowledge of the structure of man and of the chief families of the animal and vegetable world, to which must be added a knowledge of the laws pertaining to matter and force. The need for such wide and extended information had been fully recognised of late years by the altered course of study now recognised by the London University as necessary for the preliminary degree of Bachelor of Medicine.

To be educated in such an art, brought to the possessor all the advantages and graces of an enlightened education. It trained the mind to understand the laws regulating the evolution of the germ out of which his organisation sprung. It taught him the conditions governing nutrition, regulating development, or ministering to decay, the premature tendency to which it was the effort of the art to avert.

As an art it dealt in no dogmas; it regarded, as reliable and true, only that which was susceptible of demonstration and proof. It sought no converts, for the essence of its teaching was, that its followers must be for ever students, for the words of Harvey were ardently accepted by all workers, "that all we know is infinitely less than all that remains still to be known."

In this art there was no fealty sworn to authority; and only that which was ancient was loved which experience or science had proved to be true.

The sciences on which this art rested could not be learnt from books alone. The fabric of nature and of the material world must be searched and studied, and each step the student made must be steadily from one demonstrated fact to another.

The theories of incomplete observation were constantly tested by more numerous and reliable facts, and which scientific experiment eventually verified or ignored.

Thus gathering within herself the tributary streams of many branches of natural science, each contributing some truth or fact applicable to the interpretation of the laws of health and disease, medicine might consistently take her place among the arts and sciences, and claim a prominent position among the most useful and beneficent of those scientific pursuits to which the intellect of man might be devoted.

#### THE MIDDLESEX HOSPITAL.

DR. JOHN MURRAY delivered the Inaugural Address at this hospital. The lecturer commenced by urging the new students of medicine to inquire of themselves whether they were adopting a profession for which they were naturally suited. According to the comparative vivacity and force of a young man's intellect, his fitness for a profession should be gauged. If a youth afforded no evidence of predominant interest in literary study and the delights of scholastic ambition, he ought not to be encouraged to adopt a profession requiring the considerable amount of application to such pursuits demanded by medicine. He referred to the unhappy instances daily to be seen, of men possessed of excellent abilities engaged in the half-hearted

pursuit of occupations wholly unsuited to their natural turn of mind—abilities which, if they had been directed into the proper channels, would have placed the possessors in positions in which they would not only have excelled, but would have increased their enjoyment of life—perhaps, also, the depths of their pockets, and certainly their value to the public. Most young men's minds, he believed, afforded a clue, if properly scrutinised, to their natural fitness, to ascertain which was the duty of parents and guardians; and this was becoming daily more and more imperative, as free trade, the correlative of natural selection, was, in this country at least, in the ascendant. To make the most of this natural fitness, the preliminary education of the young man should be of a most liberal character. The great acuteness in the observation and treatment of disease displayed by men of the present day distinguished in medicine, does not, he believed, rest on the possession of medical facts alone, but on a sound general education, aided by natural ability for the practice of their profession. He decried the growing tendency amongst the advocates of the real, or modern, or so-called useful studies to underrate the value of classics, by the study of which we are made acquainted with the *Alterthum swissenschaft*, the spirit and power of Greek and Roman antiquity, learned from its original works. A liberal education should make a man know himself and the world, not in a narrow sense, as Matthew Arnold expresses it, "to make a man a good citizen, or a good Christian, or a gentleman, or to fit himself to get on in the world, or to enable him to do his duty in that state of life to which he is called. There is a wider and more noble sphere—to do good to mankind and to advance his fellow-creatures."

After offering a few words of advice as to the manner in which the student of medicine should proceed in surmounting the mass of work before him, Dr. Murray continued: "To assist and guide the student in his studies, medical schools have been formed, in which more or less compulsory attendance is required; the different subjects taught being arranged in such a manner as to afford a very considerable amount of assistance to the pupil. Our metropolitan system of medical schools, as it at present exists, has found many able opponents, men whose opinions carry with them great authority, and in whose views I am prepared largely to sympathise. But, while we should sanguinely look forward to a future still greater than the present in the medical education of the metropolis, there still can be no doubt that even now, with its disadvantages, London affords many unrivalled opportunities for the study of medicine unattainable elsewhere.

"The mission of a medical school, it seems to me, should be not alone to cram the student with facts, but to effect as far as possible the *Gesamtbildung*, the total medical cultivation of the student in his strictly medical studies. What is to be avoided is, that the instruction degenerate into a preparation for examination, instead of providing that the pupil may have the requisite time to come steadily and without hurrying to the fulness of the measure of his powers and character; that he may be securely and thoroughly formed, instead of being bewildered and oppressed by a mass of information hastily heaped together. What faults our medical schools do possess are in a great measure due to the baneful influences of certain of our licensing bodies, which do not demand a sufficiently high standard for qualification, and do not allow the schools time to develop the student. That systematic teaching is, as asserted, carried to an excess in them, I do not believe; in fact, the very reverse. That students should be allowed to study wheresoever and howsoever they please, as recommended by not a few, is a doctrine which I think should be resisted as opposed to reason, and a retrograde step in education. Were it possible, as is proposed, to render the examinations all sufficient as tests, which I deny they can be made to be, the more or less want of system in the preparation for these examinations would entail a waste of time and strength, and by reaction, tend to reduce the standard of examinations. It is this absence of system which I believe is the bane of education in this country. In everything we lean upon our energy and wealth to overcome the drawbacks necessarily dependent on our want of gradual training and method.

"How are students, I would ask, to be guided in their studies unless in a systematic school? where are they to learn exact habits of mind? Not in books, certainly. Most students are willing and anxious to learn if intelligently managed; and if the teacher fail, it is, in the majority of cases, as much the fault of the teacher as of the pupil. If there are those disposed to apply themselves to their work, much can be done to make them learn if taught methodically and under a com-

pulsory system. Were it not for our compulsory system, however, what would become of such men? One would stay at home and cram; another would go from place to place, 'taking tithe of mint and anise and cummin,' but neglecting the principles and more important matters of his profession, picking up crumbs which he would mould together into some crude idea representing his peculiar notions of the theory and practice of medicine, while only a comparatively small number would pass their examinations, possessed of a comprehensive medical education, and that chiefly through their inherent natural good qualities, a considerable number would probably be able to pass the examinations, however strict and searching they might be; but their minds would not have been gradually formed, and taught that exactness of reasoning which is likely to be engendered by a proper system of teaching, such as is aimed at in some at least of our medical schools. I would have you, therefore, to bear in mind that system and regularity in your work are all-important."

The lecturer concluded his address by reminding his hearers that beneficence formed medicine's highest title to respect; that their duty, their real pleasure would be found in allaying misery, in assuaging suffering, and advancing the physical well-being of man.

#### QUEEN'S COLLEGE, BIRMINGHAM.

DR. RUSSELL commenced his lecture by quoting the introductory remarks with which Burton opens the chapter on the cure of "Melancholy," because, as he observed, they present a more correct representation of the function of the medical practitioner than that which generally obtains. In place of imposing the entire responsibility in treating disease upon the medical adviser, leaving the patient to digest the medicine and swallow the advice he receives without co-operation on his own part, the author regards the patient as an active agent in effecting his own cure, and reminds him that if the doctor has a duty to perform towards him, he has also a duty which he owes to the doctor. Dr. Russell was thus led to dwell upon the two-sided character presented by the medical profession, its relation to medicine as a science, and its relation to the society in which the science is to be applied. In developing the subject, the lecturer proceeded to comment on the influence which public thought has exerted over the interests of the medical profession viewed merely in its scientific relation; noticing how, in narrating every step which has been made, the historian instinctively turns his eyes to the general state of learning at the time, and how universally medical opinion has been the reflection of the opinion of the age in which it has been formed. In one particular, however, he believed that medical science stood in contrast to the philosophy by which it was surrounded, at least in the earlier periods of its history. If Macaulay has rightly selected, as the characteristic element of the ancient philosophy, that "it disdained to be useful, and was content to be stationary," that "it could not condescend to the humble office of ministering to the comfort of human beings," then medicine must claim to have had a higher aim throughout its various fortunes, that aim being the very one which the same author advances as the distinguishing feature of the Baconian philosophy—"fruit"—"the multiplying of human enjoyment, and the mitigating of human suffering."

Dr. Russell then proceeded to regard his subject in another aspect, one always of importance, but never of so much importance as at the present day. He observed that the evils with which medical science has had to deal have been in no small measure the product of human passion, and in a still greater measure have resulted from ignorance of those laws which have been imposed by Providence as necessary conditions for the preservation of health; and he noticed that the success, or want of success, which has attended the efforts made for the removal of such evils has depended in no small measure upon the degree of intelligence with which the subject has been regarded by the public at large. This statement may be applied to disease in all its forms, but it is illustrated on a large scale by the history of nations. He glanced at the pestilences which form so prominent a feature in past ages, preceded in almost every instance by famine, the consequence sometimes of bad seasons, but rendered so fatal in their results through ignorance of agriculture, through defective legislation, and through want of free intercourse between different districts; but far more frequently the consequence of civil and foreign wars, of the evil policy of kings

and nobles, and of popular outbreaks against the violence of rapacious governors. Then he passed to other causes of public disease connected with social or private life, as exemplified by the mode of living prevalent in the Middle Ages, by the condition of the land, covered as it was by fir and morass, by the state of our prisons as revealed by Howard, of our ships and hospitals as disclosed by Lind, Blane, and Pringle, down to the present time, when sanitary inquiry is announcing the presence of evils of precisely the same kind, and is tracing up to these evils precisely the same effects.

It is of vast moment to the interests of humanity that both parties in these matters, the profession and the public, should understand their part in the responsibility to be borne. An enlightened public must be the correlative of an educated scientific body, or nothing can be done.

But there is another element besides the intellect, powerful in determining human conduct, which is closely involved in the relation held by the public towards the medical profession, and is mainly determined by the spirit in which the work of the profession is regarded. I mean, said the lecturer, the character of its several members. The medical profession is in the position of having to study science with reference to its immediate application; and the aspect in which the subject presents itself to the minds of medical men is not that of abstract truth, but of truth valuable in proportion as it can be made available for the benefit of mankind. Their discussions, therefore, must be influenced by a consciousness of the momentous nature of the interests involved, and by the knowledge that the main responsibility rests upon their own shoulders. On this account it is natural and proper that medical men should throw their whole heart into the controversy. Thus it has happened that the relation held by the public towards the advocate of medical truth has not always been consistent; sometimes he is credited with possessing precise knowledge, such as can belong to the student of physical science only; at others he is regarded with absolute scepticism because he does not, like Molière's M. Purgon, "believe in his set rules more than in all the demonstrations of mathematics, finding in medicine nothing uncertain, nothing difficult."

The language of the student of medicine will be modest in exact proportion as he has obtained a better acquaintance with his subject and a larger view of its several relations. Yet he is no stranger to the tone of authority when circumstances justify its assumption. He knows that the conditions with which he deals are regulated by fixed laws; and where such laws have been clearly eliminated he announces them with all the authority of ascertained truth. And in the operation of these same laws he recognises a limitation placed upon his own power. He knows that it is as impossible for his science to avert the effects of sensuality upon the bodily functions, as for the ethical philosopher to prevent its exerting its baneful influence upon the mind. Nor can medical science be expected to shield a community from the consequences of violating the conditions imposed by Providence for the preservation of health. Foul drains will generate fever, let science say what it will; overtaxed brains will fail; overstrained muscles will ache. But if, in a large part of her utterances, medical science wisely uses a less dogmatic tone, it is because the interests with which she concerns herself are closely interwoven with those moral and physical conditions which constitute the discipline of life, and determine a man's moral position in the world. Hence, doubtless, the reason that many of the problems of health and disease appeal to men as free agents, and call upon them to assume a share of responsibility in the use they make of the knowledge which is afforded to them.

The lecturer concluded with some remarks addressed particularly to the students of the College.

#### SHEFFIELD SCHOOL OF MEDICINE.

By ALFRED H. ALLEN, F.C.S.

Lecturer on Chemistry at the School.

AFTER dwelling upon the advantages of a knowledge of chemistry and physics to all classes of medical practitioners, and pointing out how many valuable remedies the progress of these branches of science had given the modern physician, the lecturer proceeded to treat of the nature of infection and spoke of the germ theory as one which had many arguments in its favour and received great additional support from the recent

beautiful researches of Dr. Thudichum. But there was another very ingenious theory which also explained the extraordinarily rapid development of infectious disease while ignoring the multiplication of cells by fusion.

There were many instances known to chemists, in which the presence of a minute proportion of some foreign matter acted in an extremely energetic manner to produce some chemical change, far more difficult to effect in its absence. In the same manner, Simon supposed that the infectious principle of small-pox possessed the power of causing some chemical change in the body with formation of a larger or smaller amount of the specific poison, and that the patient had the disease severely or lightly accordingly. By vaccination, therefore, all the substance susceptible of change by the virus became so altered, and an additional inoculation could produce no further quantity, so the person became insensible to its influence for some time subsequently. Some years ago, Dr. Simon obtained the opinions on the subject of vaccination of upwards of five hundred professors of medicine and surgery, at various universities and hospitals, and of all those consulted, none doubted the efficacy of vaccination, and very few believed that any disadvantage could possibly attend its universal enforcement. If, therefore, the efficacy and safety of vaccination (when carefully performed) had been thoroughly demonstrated, no man had a right to endanger the safety of others by an ignorant objection to the process. All were aware that the late extensive local opposition to the enforcement of vaccination, proceeded almost without exception, from the most ignorant people, led by interested quacks and *soi disant* "professors," who gained their adherents by apocryphal statements and "cooked" statistics. The enforcement was at one time, a dead letter as far as Sheffield was concerned, and the House of Commons recently inserted a clause in the Vaccination Act, making two small fines, the maximum penalty for omission of the precaution, thus virtually allowing a man to buy the right to spread disease and disfigurement. This was only prevented from becoming law by an amendment in the Upper House.

In further reference to the germ theory, Mr. Allen said, "the germs causing putrefactive change and originating zymotic diseases, are minute solid bodies, capable of conveyance by air or water. That the notes existing in the air consisted largely of organic matter has been long known, and has been recently demonstrated in a very beautiful manner by Tyndall. The active form of oxygen called 'ozone,' had a very energetic action on organic matter, while it is itself destroyed by various noxious emanations from putrefying matter. At present, we associated the idea of ozone with the pure fresh air of the country and seaside, while it is rarely, if ever, present in the atmosphere of Sheffield. Whether, by electricity or other means, the air of hospital wards could not be moderately ozonised, is a question well worthy of attention, and if ever ozone could be produced on such a scale, as to admit of still larger application, the benefits to humanity would be very great."

"A good and plentiful supply of water is of extreme importance to all, and though most natural fresh waters are more or less suitable for drinking purposes, they are so liable to contamination from various causes, that too much care cannot be exercised in the selection of a suitable supply, and in some localities the inhabitants might say with great propriety,

"Water, water, everywhere,  
But none that's fit to drink."

"When once water has suffered contamination by sewage or similar matter, it is very doubtful whether any process short of actual irrigation and filtration through the soil will render it safe for drinking purposes. A flow of a dozen miles had by some chemists been considered sufficient to effect the purification of a stream containing sewage, while others considered ten times the above length of flow to be inadequate. It is a fact, that when cholera was raging in Sheffield, the people of Doncaster escaped the infection, though they drank of the water of the Don after a flow of but twenty miles from the junction of the Sheffield sewer, but probably the immunity they enjoyed was due to other causes than the purification of the water. Rapidity of flows, depth of stream, and amount of impurity, being all important factors in the calculation, it is evident the special circumstances of the case in point, must receive great attention in giving a decisive opinion on the subject. But though it is often difficult to say that water is perfectly pure, the fact of previous contamination by animal matter, is by no means difficult of detection by analysis. A water giving such evidence of pollution should always be regarded with great suspicion, and should never be drunk when

any other is obtainable. No greater mistake can be made than to assume that a clear and sparkling water is necessarily pure, many of the worst specimens being agreeable to the senses. On the other hand, the water supplied by the Sheffield Water Company, has been repeatedly proved to have no injurious qualities, though it possesses a brownish tint from the presence of peaty matter. Whether the hardness of the water affected the health of the drinkers is an open question. It is true, that at Edinburgh recently, with reference to the utilisation of the water of St. Mary's Loch, it was stated in evidence by an eminent chemist, that many of those towns which had a supply of hard water had the lowest death rates; but unfortunately for the theory implied, they also proved to be towns with a far smaller population to the acre, so that the two cases are not parallel." To effect the purification of bad water, the lecturer said, "some process of filtration was commonly adopted, but great as were the advantages of charcoal as a purifier, it was without effect upon many kinds of dissolved impurities, while its action on others was of a very imperfect nature, and when the charcoal had been in use some time, the amount of impurity in the water was frequently increased. Recent investigations by Calvert, had proved that, many of the lowest forms of life could withstand a much higher temperature than had been supposed, but it might be considered pretty certain that a boiling heat, aided by a small quantity of permanganate would effectually prevent any injurious effects of organic matter present in the water. The disease germs, whether existing in air or water, might be destroyed by means identical with those found serviceable for the destruction of other low forms of life, but too many people were satisfied if they succeeded in stifling the smell alone, by the use of pastilles and other useless means. In Italy, as a preventive against cholera, they burnt juniper berries, &c., from which circumstance, combined with evidence of one's eyes and nose when travelling in that country, we were justified in concluding that the Italians were scarcely so advanced in sanitary science, as since the opening of the Mont Cenis tunnel, they had been suddenly discovered to be in engineering. It was quite certain that not only cholera, but all zymotic diseases were the result of bad sanitary arrangements, and the lecturer hoped the time would come, when the elements of sanitary science would be taught together with 'the three Rs' to every child in the kingdom. What we ought to do with the sewage of large towns was a very difficult and important question, but we must abolish at any cost those prolific sources of disease, the privies and the ash-pits of our towns. Though the latter nuisances were probably far less injurious than the privies, they might be greatly improved even by rendering them water tight. At present, the most injurious portions of the contents soaked the ground with decaying matter, while only the less objectionable portion was removed when the ash-pit was cleared out, which happened far less frequently than was proper.

"The best means of disposing of sewage, is a question at present engaging great attention, and one of the most popular plans is that of irrigation, which has been found to answer very well in certain places of moderate population, having extensive, cheap, and level pasturages in their neighbourhood. But how the advocates of this system would propose to deal with the sewage of Sheffield, I cannot imagine. The enormous amount of material, the undulating character of the ground, and the limited area of available land within a reasonable distance, are all most cogent objections to such a scheme.

"Unless a dry closet system be adopted like that of Mr. Stanford, who used charcoal, which can be repeatedly burnt and employed again, there does not seem to be any method applicable to the circumstances of Sheffield, than the old and extremely unsatisfactory plan of running the sewage into the river; but such a method, if generally adopted, would be a decided improvement on the present want of method which raised the death rate and offends the senses. In calculating the expense of rival methods of disposal of sewage, account ought certainly to be taken of the large extra water supply required for any system of water carriage, which extra outlay would be saved if it were possible to adopt a dry closet system."

In London the last weekly return gives a total of 1,411 deaths registered, being 74 above the average. Of the deaths 89 were from small-pox, and 205 from diarrhoea, the first-named disease causing greater fatality than for five weeks previously.

### CLINICAL LECTURES

ON THE

### DISEASES PECULIAR TO WOMEN.

By LOMBE ATTHILL, M.D. Dub.,

Fellow and Examiner in Midwifery King and Queen's College of Physicians; Obstetric Physician to the Adelaide Hospital, Dublin.

#### LECTURE XIV.

*Cancer of the Uterus—Pathology of—Forms met with in the Uterus.—Medullary Cancer—Course of.—Epithelial Cancer—Symptoms of.—Hæmorrhage.—Pain.—Fœtid Discharge.—Cauliflower Excrescence.—Amputation of Cervix.—General Treatment.*

I PROPOSE to-day, gentlemen, to call your attention to the subject of cancer of the womb, of which disease we have had, unfortunately, several examples recently. You must not suppose that the subject is unimportant because the disease is in all probability not susceptible of cure, for you can sometimes prolong life, and can always alleviate suffering; besides, it is of great importance that you should be capable of recognising the existence of cancer and of being able to pronounce that a disease which may simulate it is not malignant. The idea of cancer is ever present to the minds of women, and few of them suffer from any chronic ailment, the symptoms of which are referable to the uterus, without fearing that they are the subjects of that dreadful disease, and are sure to question their medical attendant closely. I need not delay to point out how injurious it would be to your character were you to pronounce a woman to have cancer who laboured under such a comparatively innocent disease as inflammatory hypertrophy of the cervix uteri. Or how lamentable would be the consequences were you to assure your patient that nothing serious was wrong with her when death was inevitable. Yet both these mistakes are frequently made, mistakes for which there is but little excuse.

Cancer of the womb is most frequently met with in women who have passed or at least attained middle age, but this rule must be received with great reservation. Women under thirty are not unfrequently attacked with it, and it is important that you should bear this in mind, lest misled by the youth of your patient, you should give a favourable prognosis on what was in reality a hopeless case. Still, it is in the decade between forty and fifty the greatest proneness to the disease manifests itself, 50 per cent. of all the cases occur between these ages. This, you are all aware, coincides with the period at which what is termed "the change of life" in woman occurs, when menstruation and the other functions of the reproductive system cease.

There is no disease the symptoms of which are so uncertain as those which usher in cancer of the uterus; very frequently, indeed, it develops itself so insidiously that the patient's attention is only attracted to what she supposes to be a very recent malady, when in reality our first examination proves the disease to be far advanced towards its fatal termination. The patient, Mrs. S., in No. 6 ward, is a striking example of this fact. She believes herself to have been in good health up to the 4th of last month, when hæmorrhage set in; but this is impossible, for the entire of the vaginal portion of the cervix is already destroyed, the uterus is firmly fixed by the deposit of cancerous matter in the surrounding tissues, and a gaping opening, surrounded by a jagged, indurated, and ulcerated mass, is all that is left of the lower segment of the uterus. Her end cannot be far distant. Yet it is but a month since her attention was first attracted to her condition.

Supplement to the Medical Press and Circular.

4th Oct 1871.

---

In London the last week deaths registered, being deaths 80 were from small the first-named disease causing greater fatality than 1014 a month since her attention was first attracted to her five weeks previously.

Now, Gentlemen, I must take it for granted that you all know something of the pathology of cancer. This is a part of the subject which I cannot dwell on at any length in a clinical lecture—I shall only say, lest I should have any hearers who are altogether ignorant of the subject, that this dread disease consists primarily of the deposit, or more properly of the development of an abnormal material in tissues hitherto healthy, and which consisting in a great degree of cells of peculiar formation, has a great tendency to invade the neighbouring structures, and at a later period to take on a process of destructive ulceration. Dr. West, adopting the words of Müller, defines cancer to be “Those growths which destroy the natural structure of all tissues, which are constitutional from their very commencement, or become so in the natural process of their development, and which, when once they have infected the constitution, if extirpated, invariably return, and conduct the person who is affected by them, to inevitable destruction.” But, in truth, the origin of these growths is a puzzle to pathologists. Of the various forms of cancer, two only are as a rule met with in the uterus—namely :

- 1st, the Medullary, and
- 2nd, the Epithelial.

Instances no doubt of the true scirrhus, or hard cancer, and of the colloid, or gummy cancer, are recorded, but they are exceedingly rare, and we may for the present set their consideration aside, the more so as with the exception of the greater slowness of progress, there is not any essential difference between the course of these two varieties and that of the medullary form. As already stated, the first step in the production of the disease is the growth of the cancerous matter in the substance of the healthy organ, and I may here remark that it is in the vaginal portion of the cervix uteri that this nearly invariably occurs. Why this should be is not clear, but such is the fact. In a few rare instances, however, the body, or fundus, is the seat of the disease. Cancer appears in general first to attack the submucous tissue of the vaginal portion of the cervix, and subsequently to extend to its muscular structure. Very soon the adjacent parts become implicated. Cancerous matter is deposited between the uterus and the bladder anteriorly and the rectum posteriorly, and in consequence the cervix becomes fixed and immovable. By-and-by the mucous membrane at some point gives way, and an ulcerated surface is formed. The feeling communicated to the finger by this ulcer is unmistakable. It is hard, irregular, with sharp edges, and generally bleeds on the slightest touch. The ulceration extends with considerable rapidity; occasionally, indeed, granulations arise on its surface, and at one point an attempt may be made at cicatrization; but this soon gives way, the granulations disappear, and the disease spreads as before.

When this stage is reached we generally find a most characteristic discharge present. It is dark in colour, profuse, and fetid. Sometimes the fetor is so strong and unmistakable that it is possible to diagnose the disease from the smell alone, even before we make any examination; but this is not always so. The patient whose case I have alluded to is an example of this latter condition, for though the disease is in such an advanced state, she has but little discharge, and that by no means fetid. Hemorrhage, too, if not previously present, is now nearly sure to occur, and it is very probable that the decomposition of clots of blood within the uterus may be one though not the sole cause of the fetid character of the discharge. The disease is all this time spreading upwards, and engaging the body of the uterus, and sometimes cancerous masses project into its cavity, while at the same time the vagina also nearly invariably becomes involved. Sometimes, the posterior wall being affected, the disease extending backwards till the rectum becomes implicated; but more commonly it is the anterior wall which is chiefly engaged.

When life is prolonged beyond this stage the ulceration may destroy not only the muscular structure of the vagina but also the adjacent walls of the bladder or rectum, or

even of both. And then to the sufferings previously experienced are added the miseries incidental to vesico or recto-vaginal fistula. Under such circumstances death is brought about by a process of gradual exhaustion; more frequently, however, the patient sinks at an earlier stage from the effects of the constantly recurring hemorrhage. The following accurate description of the *post-mortem* appearances usually met with in cases of cancer is given by Mr. H. Arnott, in Vol. XXI. of the “Transactions of the Pathological Society of London”: “It will be noted that in nearly every case the seat of disease is the same. The os and cervix are more or less completely destroyed, and the foul ulcer resulting includes the upper part of the vagina. In more severe cases the floor of the bladder is invaded, and perhaps freely perforated, whilst even the rectum may be opened into the vagina, the uterus itself being sometimes almost wholly consumed in the general havoc. In one remarkable case the os and cervix remained, whilst the whole body of the uterus was destroyed by cancer.” The pelvic glands are frequently the seat of secondary cancerous deposit, while in not a few the ovary and even more distant organs, including the heart and lungs, become implicated in the disease.

Now, with respect to epithelial cancer, which is the other form so commonly met with in the uterus. It differs from the medullary in this, that it is generally developed as an outgrowth, or excrescence from the cervix uteri. In general it seems first to appear as a tubercle, this increases rapidly, after a time it becomes fissured, and branches out, so as to form a soft irregular mass, which from its resemblance to the vegetable of that name is commonly called “cauliflower excrescence,” a resemblance however which is frequently wanting. The discharge to which it gives origin is very profuse and watery, but is not generally so fetid as that proceeding from the medullary form. This growth often attains considerable size, sometimes forming a mass which fills the whole vagina, and being very vascular, is invariably accompanied by hemorrhage. Epithelial cancer occasionally attacks the vagina as a primary disease. We have had two examples of this recently in hospital: in one the superficial ulceration extended to the very vulva, and the patient sank worn out by pain and repeated though trifling attacks of hemorrhage. In her case the entire surface of the vagina was constantly covered with a dark pulsatious slough. The other was admitted for profuse hemorrhage, which threatened life. This was found to proceed from a spot on the anterior wall of the vagina, not larger than a split pea; it was hard to the touch, and had a puckered appearance. In a third case a large mass of epithelial cancer grew from the posterior part of one labium.

Having thus given you an outline of the course which cancer usually runs, I must return to the symptoms it gives origin to. In the early stages at least they are most vague and uncertain—to such an extent, indeed, is this the case, that we not infrequently meet with instances in which the entire of the lower portion of the cervix uteri has been destroyed by the ravages of disease, and yet the existence of cancer has never for a moment been suspected either by the sufferer herself or by her friends. The patient to whom I have already referred affords a well-marked example of this. She is a married woman, æt. fifty, has given birth to twelve children, and has had two miscarriages. Six years ago she ceased to menstruate, and was perfectly free from any symptom of uterine disease up to the 6th of last December, when she noticed a discharge which resembled in all respects natural menstruation, being red in colour, free from smell, moderate in quantity, and not accompanied by pain. The appearance of this discharge did not cause her any anxiety, and she continued apparently to enjoy her usual good health till three weeks ago, when (on the 4th of January) she was suddenly attacked with profuse hemorrhage, which has not as yet entirely ceased. At no time has there been any fetid discharge, nor did she suffer pain, except a dull back-ache, apparently the result of debility. But on making a vaginal examination we found the uterus

fixed by the deposit of a large quantity of cancerous matter, into the tissues surrounding the organ, while the lower portion of the cervix is already destroyed by the process of ulceration, and a wide gaping irregular opening leads up to the body of the uterus. Now, this case is very instructive—it shows how insidious the disease may be. Not only is there an extensive deposit of cancerous matter, but a considerable portion of the uterus has been destroyed by ulceration, and yet till three weeks ago she presented no symptom of disease except the slight coloured discharge which appeared four weeks' previously, and which she believed to be a return of normal menstruation. Moreover, it shows that you may have extensive cancerous ulceration without its being accompanied either by pain, fetid discharge, or any appearance of cancerous cachexia. But cases of cancer usually present all these symptoms in a greater or less degree. You will, therefore, be correct in considering hæmorrhage, fetid discharge, pain, and cancerous cachexia as being the symptoms of cancer of the uterus, though none of them are necessarily present. I shall say a few words on each.

First, with respect to *hemorrhage*; it is the most common and most important of them all; it is also the one which, as in the present instance, is generally first noticed. If the patient has not ceased to menstruate, she will probably tell you that her attention has been attracted by observing the catamenia to become much more profuse, and to last a longer time than formerly; then that the discharge has commenced to appear irregularly, returning at intervals of a few days, till finally it is almost continuous. If, on the other hand, she has passed the "climacteric" period of life, the first symptom most probably will be—as was the case with the patient first alluded to—the sudden appearance of hæmorrhage, which is occasionally profuse. Sometimes hæmorrhage occurs before any ulceration has taken place; this is especially likely if menstruation have not previously ceased; but it is after ulceration has occurred that it, as a rule, becomes so prominent, and often so alarming a symptom. Cases, however, are met with in which it is not present at all; they are, however, rare. It may not be an early or a prominent symptom, but seldom, indeed, is it altogether wanting. In general, as the disease advances, and the ulceration spreads, the bleeding becomes more profuse, sometimes in the form of a continuous draining, more frequently as well-marked attacks of hæmorrhage, occurring at short intervals, often alarming, and threatening life itself, sometimes even proving fatal, though much more frequently the patient dies from the exhaustion consequent on the frequent losses of blood.

*Pain*.—Of all the symptoms indicative of cancer, pain is the most fallacious. Cancer, in its early stage, is, without doubt, in general a painless disease. This statement is, I am aware, directly at variance with preconceived notions. Women invariably associate the idea of pain with the existence of cancer, and believe the absence of suffering to be impossible; this is, however, a popular error. I have but to refer to Mrs. S—, the patient to whose case I am especially calling your attention as a proof of this. Here is a woman dying of cancer, and yet she is entirely free from pain; I fear, however, that her prospect of this immunity from suffering continuing to the last is very doubtful, for as the disease progresses pain is seldom absent; frequently, indeed, it becomes almost unbearable, so terrible are the paroxysms, so excruciating the agony. Bear in mind, however, that this applies to the stage of ulceration only. This absence of pain forms one of the chief diagnostic marks between chronic inflammation of the cervix and *cancer in its early stages*. When you meet with a patient who has for a lengthened period suffered from pain, referred to the back, to the uterine, and especially the ovarian regions, shooting down along the inside of the thigh, and who, on examination, proves to have a thickened indurated cervix uteri, the probability is that this is due to long-continued inflammatory congestion, and not to malignant disease.

But, as already mentioned, this immunity from suffering generally ceases after ulceration has taken place; we find,

too, that the attacks of hæmorrhage often come on during severe paroxysms of pain, and seem to relieve them, leading to the supposition that the pain is due to some form of congestion, for were it not so, the hæmorrhage could hardly bring relief, as undoubtedly it often does; but be this as it may, the fact remains, that the terrible sufferings in the second stage of the disease present a marked contrast to the immunity experienced in the first; and though there may be occasional instances in which pain is absent even to the last, they are unfortunately rare.

*Fetid discharge*.—This, too, is a symptom of variable occurrence; ordinarily a colourless discharge accompanies the early stage of malignant uterine disease, but not to an extent sufficient to alarm the patient; as changes in the cervix take place, however, an open cancerous ulcer is formed, the discharge assumes a different character, it becomes more profuse, dark-coloured, and fetid. In many instances, this odour is so marked, that without asking a question or making an examination, the experienced physician can pronounce the patient to be suffering from malignant disease. Sometimes the fœtor is intolerable, and the profuseness and acridity of the discharge so great as to add materially to the patient's suffering, by giving rise to painful excoriations. In epithelial cancer the discharge is more watery, and seldom so fetid as in the medullary form.

Both the cases of cauliflower excrescence which have been for some time past in our ward, differ in many respects from that of Mrs. S—, who afforded us an illustration of the medullary form. One E. K—, aged only twenty-three, is five years married, but has never been pregnant. She states that she was quite well till about two months ago, when menstruation became *suddenly* profuse; shortly afterwards she perceived a fetid watery discharge to appear in the interval between each period. She suffered from severe left side pain of a paroxysmal character, which became aggravated before each attack of hæmorrhage, and also by diarrhœa. On examining her after admission, the whole of the upper third of the vagina was found to be occupied by a large mass of epithelial cancer; the disease had also extended to the anterior wall of the vagina. Her case was hopeless; we could but relieve her pain by subcutaneous injections, and check the discharge by astringent lotions, and by the exhibition of gallic acid, acetate of lead, opium, &c. She died shortly after.

In the other case, I at first entertained hopes of being able to save, or at least to prolong life.

This patient was a young woman, aged twenty-eight, five years married, and had given birth to one child, who, at the period of her admission into hospital, was four years old: in the interval which had elapsed since its birth she had had three miscarriages, the last occurring twelve months prior to her admission. Her health had been very good up to October, 1869, when she, for the first time, remarked a sanguineous discharge, which appeared in the interval between two regular menstruation periods. It only lasted three or four days, and then ceased, but subsequently reappeared at irregular intervals during the next four months, never lasting more than a few days; and as her general health continued good, she paid no attention to it. In March last this discharge became more profuse, and she was admitted into the hospital on the 16th of April. She was in a very anæmic condition. She complained of weakness and of pain in the back, but of nothing else. The discharge, which was very profuse, was of a sanguineous watery character, and not very fetid. On making a vaginal examination, a cancerous mass, about the size of a hen's egg, was found, growing mainly from the posterior lip of the os uteri; the anterior lip was also engaged, but in a less degree. The vagina was not implicated in the disease, the uterus was moveable, and on passing the finger upward, the cervix uteri appeared to be perfectly healthy. I therefore thought it to be one of those cases in which it would be justifiable to give the patient a chance of prolonging life by operation, and determined to attempt the amputation of the entire of the cervix uteri

above the diseased portion. This was done accordingly with the écraseur. Much difficulty was experienced in getting the chain round the cervix, the mass being large and filling up the vagina. However, after some little manipulation, I succeeded in encircling the cervix above the growth, but the moment I attempted to constrict the cervix by tightening the chain, the apparently healthy tissue yielded, the chain of the écraseur became entangled and embedded in a mass of soft cancer, and I found it impossible to remove the entire of the cervix. We succeeded, however, in getting away a large portion, and the stump was then freely cauterized with strong nitric acid. The patient experienced no pain subsequently, and she improved greatly after the operation; the hæmorrhage entirely ceased; she put up flesh, and was discharged after a few weeks. I was aware at the time that this improvement could only be temporary, and I was not, therefore, surprised when the poor woman again sought admission in December last. She was then in a hopeless condition, dying rapidly, and she expired in the beginning of the present month. On making a *post-mortem* examination, the body of the uterus was found to be perfectly healthy. The cavity did not exhibit the slightest trace of disease, which was entirely confined to the lower portion of the cervix, from which the cancerous mass could be seen growing. The vagina was also engaged, which had not been the case when she was first admitted. This case presented four points of interest. First, the age of the patient; it showed at what a very early age this form of cancer may attack the uterus. Secondly, it illustrated the possibility of hereditary taint, as she stated that her mother and two of her own sisters had died of uterine cancer. Thirdly it showed in what an insidious manner epithelial cancer may come on. When she was admitted she was in a hopeless state, and yet believed herself to have been ill but for a few weeks, and complained of weakness only. Lastly, as to the operation. It proved how very unpromising it is. However, this was a case in which it was justifiable, and the woman's life certainly had been prolonged by it.

As a commentary on this case the following extract from Dr. Graily Hewitt's work is very appropriate:—"As a palliative measure frequently, as a curative measure occasionally, amputation of the cervix uteri (in such cases) is a valuable operation; it may possibly prevent a fatal result altogether; it will almost certainly postpone that fatal result, even when inevitable. The bleeding and the copious exhaustive discharge are at once arrested—and for a time the source of danger is removed." I can add nothing to this passage; and though in cases in which extirpation is out of the question, I shall continue to use nitric acid or caustic potash as I have hitherto done, or try the acid nitrate of mercury as suggested by Dr. Baker, of New York, or even perhaps that rather unmanageable remedy—bromine, which, according to Dr. Routh, "not only arrests the disease locally, but also the cachexia which accompanies it." I agree with the observations of Dr. Kidd in the *Dublin Quarterly Journal* for May, 1871,—"That amputation, where it can be performed, is not only a safer, but a more efficacious and less painful mode of treatment" than any of these.

I have hitherto spoken of cancer as being a disease of the cervix uteri, and in the very great majority of instances this is true; but even to this rule there are exceptions, though they are very rare. The only example of it which has come to my knowledge was the one brought under the notice of the Pathological Society by my colleague, Dr. James Little. Neither the rectum, bladder, vagina, nor cervix uteri were invaded by the disease, but the whole of the body of the uterus seemed to have been converted into a mass of encephaloid cancer, and yet had a speculum been introduced in this case, the os would have been found small, and without any appearance of disease. With respect to such cases as these I have only to say that, impotent as we generally are for good when cancer attacks the cervix, we are utterly powerless when the disease originates in the body of the womb.

When speaking of chronic inflammation of the cervix uteri, I mentioned that the induration which it produces has been mistaken for that which results from cancer. I think I shall best enable you to form a correct diagnosis between these two affections by following the example of Dr. West ("Diseases of Women," p. 384), and arranging the symptoms of both in a tabular manner, so that you may the better be able to compare them.

*In Chronic Inflammation of Cervix.*

*In Cancer.*

The history of the case is always chronic, often dating back several years.

History—Symptoms seldom noticed till within a comparatively recent period.

Pain—always present; generally more severe over left ovary than elsewhere.

Pain—Seldom felt in the early stages; most severe in the back.

Menstruation scanty and frequently painful.

Menstruation—If patient be young will be increased; if advanced in life, hæmorrhage may be the first symptom noticed.

Digital examination—Cervix feels hard to the touch, but smooth; pressure with the finger causes pain.

Digital examination—Cervix indurated, uneven and nodulated; pressure does not cause pain.

Uterus—Moveable.

Uterus—fixed.

Vagina—Not implicated.

Vagina frequently implicated.

Discharge—Inodorous and muco-purulent.

Discharge—Generally foetid.

Having given an outline of the ordinary course which cancer of the uterus follows, and dwelt on its leading features and symptoms, I must in conclusion allude to the treatment. Unfortunately we can seldom do more than alleviate the most prominent symptoms. With the view of deadening the pain, opium in some shape or form must still be our main reliance; chloral will often fail, if the sufferings be excessive, even to produce sleep. If it does not I prefer it to opium. You will have to give it in doses of from twenty to forty grains at bedtime. One objection to the administration of this medicine in large doses is the quantity of fluid in which it is requisite to have it dissolved, namely, ten grains of the salt to an ounce of fluid. I think you will find that syrup of orange peel best cloaks its nauseous taste; the addition of half a grain of codia to each dose greatly increases its hypnotic powers. Opium is best administered either per rectum, in the form of suppositories, or by being injected subcutaneously, commencing with  $\frac{1}{2}$  or  $\frac{1}{4}$  gr. of morphia. No doubt the subcutaneous injection of morphia acts more rapidly, and its effects last longer than those of opium administered in any other manner, while it is, I think, less deleterious in its after consequences. Of astringents administered with view of checking the hæmorrhage gallic acid is, I think, the best. If the bleeding be very severe you may be compelled to plug the vagina; but I prefer in these cases, endeavouring to stop it by the direct application to the cervix of a pledget of cotton saturated with a strong solution of the perchloride of iron in glycerine.

To lessen the factor of the discharge, you had better add half an ounce of Condy's fluid to a pint of tepid water, and direct this quantity to be thrown up the vagina at least twice a day. Another lotion which is sometimes useful both in allaying the pain and lessening the discharge is a solution of nitrate of silver of the strength of ten grains to the ounce—two or three ounces

of this should be injected at a time. Of internal remedies, arsenic and iron are the only ones which will effect any good, indeed I confine myself nearly altogether to the administration of the latter; and of its various preparations I prefer either the tincture of the perchloride or, if the stomach be irritable, the ammonio-citrate of iron. The diet should of course be nourishing, but unstimulating. In cases of cauliflower excrescence there is always the chance, if the case is seen early, of your being able to prolong life by amputating the cervix, or of destroying the growth, by repeated applications of caustic potash; this latter I effected in the case of a woman aged nearly sixty. The disease however returned after the lapse of a few months, and then proved fatal. Indeed, no matter what treatment be adopted, you should always let it be clearly understood that the result is very doubtful.

## The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 4, 1871.

### THE WINTER SESSION.

THE London Schools are open. The Introductory Addresses, which in spite of some suggestions that they should be suppressed, have been delivered, only one School dispensing with the time-honoured custom. Many a young and ardent youth is now in full harness preparing for the great work of life in one of the noblest spheres of human action. We join in the many good wishes that have greeted them, and shall refrain from repeating the valuable advice that has been offered by teachers well qualified to give it.

These teachers, too, are hard at work in the duties for which they have been preparing through years of anxious toil, and some have been successfully discharging through many Sessions. We are able to present our readers with accurate reports of some of these Addresses, and shall perhaps be able to complete the abstracts in our next. One Address we give in full. It speaks, therefore, for itself, and needs no word of recommendation from us. We cannot however, forbear to remark that it is quite as interesting to the old as to the young. Dr. Little spoke to the goodly assembly at the great East-end Hospital, with the authority of one who had successfully taught for many

years within its walls. He sketched the progress of our art from the time when he, as a student, entered the same school, a time so long gone by that only one of his fellow students at that time was present to listen, and he, as well as the lecturer, a retired member of the Staff.

Mr. Curling has fulfilled his time as surgeon, as Dr. Little has his, as physician to the London Hospital, and some of those who with us have been the pupils of these men, could not but feel happy at the opportunity of being present at the interesting occasion which brings old students of the same *alma mater* together, carrying them back to the days gone by, when they looked forward to times upon which they now look back.

We have no wish to see Introductory Lectures given up. It may be that much good advice is unheeded, but that is no reason it should not be given. It may be that it is less needed; still, that is no proof that it ought to be ignored. We know that in many cases it has been a fresh starting point in the student's career, and we would not deprive him of a possible incentive to work with a will in the path of duty and righteousness.

Besides all this it is well for old students to gather now and again in their old school, to come into contact with their fellows, and compare notes of their careers, to renew their interest in the great educational institutions to which they necessarily owe a certain loyalty, and to stimulate each other by so doing to hold on bravely in a calling in which both young and old should begin, continue, and end, as acknowledging themselves only STUDENTS.

---

### TWENTY-FIFTH REPORT OF THE ENGLISH COMMISSIONERS IN LUNACY TO THE LORD CHANCELLOR.

THIS important Blue-book was issued a month ago, and contains, as usual, a large amount of material.

The number of insane persons, of all classes, in England and Wales on the 1st of January last, were, according to returns made to the Board, 56,755; being an increase upon those of the former year of 2,042. These numbers do not include 204 lunatics so found by inquisition, and residing under the control of these committees, elsewhere than in asylums, hospitals, and licensed houses. There were 28,979 lunatics in county and borough asylums; 2,390 in regulated hospitals; 4,688 in licensed houses; 354 in military and naval hospitals; 460 in state criminal asylums; 392 were private single patients; whilst 12,161 were in workhouses, and 7,331 were out-door paupers. Of the 56,755 patients recorded on the 1st of January last, 6,454 were of the private class and 50,301 were paupers.

In 1871 the population of England and Wales was about 22,704,108, and this gives us a ratio of 2.49 lunatics, or persons of unsound mind, per 1,000 of the population of this part of the British Islands. In the year 1861, when the population was 20,119,314, the insane were estimated at 39,647, or were in a ratio of 1.97 to the whole population, so that this would appear to indicate that insanity is really more prevalent than it used to be in this country, an opinion held by some, but explained away, or attempted to be explained away, by others. There are now 176 asylums, hospitals, and licensed houses for the insane in England and Wales, 50 of which are county and borough asylums, and 16 registered hospitals. The recoveries (it is stated) of the past year, 3,968, have been, as compared with the total admissions, at the rate of 34.14 per cent. The percentage of deaths in 1870, calculated on the average daily number resident, has been 10.29; and calculated on the total number of patients treated it was 7.94.

Notwithstanding the efforts to keep pace with the continued increasing pauper lunatics, many asylums are overcrowded; and in Middlesex, Surrey, Lancashire, and Yorkshire much inconvenience has been experienced, and patients belonging to those counties have, of necessity, been sent to distant asylums in all parts of England, or have been unduly kept in workhouses for long periods, debarred from all medical treatment. In Yorkshire and Lancashire this evil will shortly be remedied by the opening of two large asylums now building; but the Board has entirely failed to induce the Justices of Middlesex to make any provision to meet the constantly and rapidly increasing requirements of the insane poor. The new Metropolitan District Asylums at Leavesden and Caterham have been opened, and already a large number of patients have been received in them, greatly to the relief of the overcrowded wards of the London workhouse, but they can now afford little relief to the county asylums, as the proportion of patients relieved at Hanwell and Colney Hatch, who could properly be removed to these establishments, is necessarily very small. The inadequacy of the accommodation provided for the pauper lunatics of the county of Middlesex, has frequently been brought under the notice of the Government by the Board. Last year they stated that the Secretary of State had directed the attention of the county magistrates to the subject, and that a committee had been appointed to consider it. Both the Metropolitan Asylums at Leavesden and Caterham, each capable of containing 1,600 patients, were opened early in October, and that committee reports that, up to the present, 1,100 patients had been received at Leavesden, and 350 at Caterham. In the correspondence which has taken place on this subject between the Home Office and the Board, the latter expressed its opinion to Mr. Secretary Bruce, that so long as there exists a necessity for keeping patients in out-county asylums and licensed houses, the Justices of the county of Middlesex, cannot be deemed to have made proper statutory provision for their insane poor.

In their last report the Board drew special attention to the importance of making post-mortem examinations, as far as possible, in cases of all insane patients dying in asylums and licensed houses. At the same time they expressed the opinion that such examinations should not be made contrary to the wish of the relatives of the patients, or without giving them an opportunity of objecting thereto. A larger proportion of post-mortems to deaths has taken place this year. The boroughs of Portsmouth and Southampton are still without asylum accommodation for their pauper lunatics. The branch establishment connected with Bethlem Hospital, is at Whitley, near Godalming, and is calculated to contain 40 convalescent cases. The Royal Albert Asylum for Idiots and Imbeciles of the seven northern counties was registered as a hospital in August last. The building is expected ultimately to afford space for 600 patients. Nearly £78,000 have been raised for the building by subscription throughout Lancashire, Yorkshire, Westmoreland, Durham, Cheshire, Cumberland, and Northumberland. There are 126 patients of the Indian Army under the care of Dr. Williams, in Hackney, at Pembroke House; 16 to 20 gentlemen at Blackland's, in Chelsea; 140 private and 240 pauper patients at Bethnal House. At Brooke House, Clapton, there are between 70 and 80 patients, and at Camberwell House about 400, of whom 180 are private and 220 paupers. At Clapham Retreat there are 16 to 20 patients, and at Earl's Court, Brompton, about 30 ladies are received. There are 16 to 20 patients at Effra Hall, Brixton; and Grove Hall, Bow, contains chiefly insane soldiers, 250 at last visit, with 120 private patients and 70 paupers, females. Halliford House, Hayes Park, Hendon House, and Hoxton House are spoken of, the last being one of the oldest licensed for pauper patients. It contained lately 323 patients.

The question of the legality of receiving into workhouses, as insane, persons who are not paupers, but are

paid for by their relations is gone into. Persons who may have become troublesome or obnoxious to their relatives may, on light grounds, be considered insane; and, being sent to the workhouse, may be detained therein without any of the legal forms required by the Legislature on sending patients to asylums, and which alone authorise their being deprived of their liberty. The Poor-law Board expressed their opinion that this practice ought to be discouraged.

## Notes on Current Topics.

### Burying Alive for Scurvy.

DR. W. DOMETT STONE, writing to the *Times* last week that, in connection with former communications of his on the subject of scurvy, a correspondent writing under the *nom de plume* of "Nearchus," stated that he remembers hearing many years ago some South Sea whalers speak of burying those sailors who were much afflicted with scurvy, in order that they might receive in perfection, direct from the earth, that benefit which they indirectly derived through the medium of esculent roots. The writer of the letter adds that he does not remember with sufficient accuracy all the particulars of the "burying process," and he never witnessed its performance, but they selected spots sheltered from the sun's rays, removed the turf and sufficient earth for the patients to lie down as they would in bed, and be covered with earth instead of bed clothes. The patients were attentively watched and removed whenever they desired. This process, we are told, was repeated daily, and effected early recovery.

### Increase of Relapsing Fever in Liverpool.

At the last weekly meeting of the Workhouse Committee, it was stated that relapsing fever was on the increase, and that the number of that class of patients was thirty-three in excess of the accommodation. It was suggested that the "German" sheds should be again devoted to their accommodation, and the committee sanctioned that arrangement.

### British Medical Wit.

A PARAGRAPH has been forwarded to the daily papers by a medical contemporary, to say that if Gambetta be really suffering from *phlebitis* it is a more painful complaint than the name implies.

"What does this mean?" said a lady the other day; adding after a moment, "To extract a joke out of the word really requires a pronunciation entirely *British*."

### Government and Army Surgeons.

ONE of our Military contemporaries has the following—  
"We agree with the MEDICAL PRESS that some slight acknowledgment should be made of the services rendered during the late campaign by Drs. Gordon and Wyatt. Both officers went out under War Office orders, and, upon their return, were called upon to furnish reports to headquarters. Dr. Wyatt's services would appear, at least, to merit a C.B., whilst Dr. Gordon's claims might be favourably considered when the next vacancy occurs amongst the Inspectors-General."

THE Medical Society of London will hold its first meeting on the 16th inst.

### The Hampstead Hospital.

THIS inquiry still "drags its slow length along"—filling columns upon columns of the daily papers with details that must be sickening to professional men. We do not therefore propose to imitate our contemporaries by reproducing them in their incomplete form; still less do we think of anticipating the result.

It may be, however, worth while to remark that months ago the *MEDICAL PRESS AND CIRCULAR* drew attention to a circumstance that might have led to earlier investigation or even have prevented some of the things that have since occurred. We were then the first to comment on the management of this institution, and to give publicity to a fact that ought to have received earlier *official* attention.

### Cholera.

"THE Pilgrims!" That is the exclamation we are beginning to hear as men call to mind how the pilgrimage to Mecca has several times coincided with the outbreak and spread of the pestilence, for which journalists are persuading us we must be prepared. It is told on every side that the time of this pilgrimage is at hand, and many are the fears the event inspires. We still hope for escape, though we should be the last to encourage any abatement in the sanitary precautions that are being taken. Indeed, would these efforts were more general—more sustained—more thorough.

Still, we admit that there is much good sense in a recent remark of the *Boston Medical and Surgical Journal*, who thinks that the general press by sensation articles on topics of this kind may inspire a greater terror than is wholesome. It is well the public should be stirred from its apathy on sanitary matters, and in the presence of a great danger which may be much diminished, terror may prove a great benefit to the community.

Should the scourge reach us, we should do well to look at it calmly, and, having taken all precautions, refuse to abandon ourselves to fear.

The Profession is at least better acquainted with the disease, and even the public cannot look upon it as so mysterious as it seemed in former epidemics. It is highly desirable they should cultivate confidence in medicine, and in the earliest stages give the same chance to our art as they would in many other diseases.

### Disinfection.

EXPERIMENTS have been made by Prof. Hoppe-Seyler, and Dr. N. Zapolsky, which are related in the *Med.-Chem. Unters.*, 1871, pp. 557-581. The action of carbolic acid on albuminous matters and on ferments being investigated, it was found that the acid precipitates albuminous liquids only when they are neutral, or nearly so, and the acid is in almost saturated aqueous solution. Neither the formation of hydrocyanic acid from the fermentation of bitter almonds, nor the generation of oil of mustard, nor the conversion of starch into dextrine and sugar by diastase or saliva, is prevented by carbolic acid. The solution of fibrine by the gastric juice was prevented, but only in presence of a large quantity of acid.

The ferments operated upon were such as are formed of chemical insoluble substances. Pasteur's views are not admitted.

The serum of pus, filtered and perfectly clear, and hy-

drocele fluid, were placed in tubes hermetically sealed; others were loosely corked; they were exposed to varying temperatures for various periods of time. They underwent putrefaction, whether living organisms were present or not; the rapidity of the process was solely dependent on temperature. One fluid was corked at a temperature of 65° F., another put in an hermetically sealed tube at 108°. After a time, the former swarmed with monads and vibriones, but had undergone much less putrefaction than the latter, in which no signs of life or organisation could be detected.

On adding carbolic acid to a putrefying albuminous solution, life ceases when 1½ per cent. of acid has been added, with as much as 1 per cent. of the acid putrefaction goes on. It seems that the acid acts much in the same way as heat, and that coagulation is necessary to arrest fermentation.

Cholesterine disappears in putrefying solutions, so that, instead of being a product of the splitting up of albumen by fermentative changes, it is more probably a product of oxidation.

From these researches, it would seem that, in any attempt to disinfect, we should not only destroy the living organisms, but the ferment itself, which Hoppe-Seyler and Zapolsky think much more difficult. To remove the offensive gases set free in putrefaction, has no more effect than to get rid of carbolic acid in alcoholic fermentation. It is conjectured that disinfectants act by precipitating ferments. Sulphurous acid is recommended as the most powerful disinfectant. Half a drachm or a drachm of sulphur, burned in every 100 cubic feet of space to be purified, will set free 1 or 2 per cent. of the gas in a room, and none of the organisms can grow, in such an atmosphere.

ONE of the Medical Societies of Paris proposes to exclude Germans. The Biological Society has refused to adopt this course.

THE cholera in Turkey is assuming alarming proportions. Seventy persons died of the disease in Constantinople on Friday last.

THE next Triennial Prize of £300 will be given by the Committee of the Astley Cooper Fund, in 1874, for the best essay or treatise upon "Injuries and Diseases of the Spinal Cord." Essays must be delivered at Guy's Hospital before the 1st January of that year.

THE remains of the late Mr. Solly, F.R.S., were removed from his late residence in London on Saturday last, and deposited in a vault at Chislehurst Church, Kent, in the presence of a numerous assemblage of the Profession. It is contemplated by his former students at St. Thomas's Hospital to erect a splendid memorial to the memory of their esteemed and talented teacher.

A CURIOUS death took place on the 20th ult. at the London Hospital, which may be said to be due indirectly to chloroform. On recovery from the effects of the anæsthetic—administered for the operation of strabismus—the patient vomited, and then made a sudden inspiration which carried the vomit into the air passage, by which he was asphyxiated. An inquest was held, and the verdict of "Accidental Death" was recorded.

THE arrangements for medical attendance on workhouse inmates were discussed at the West Derby Guardians. It was agreed there shall be a resident medical officer at the Mill road house at a salary of £135, and a non-resident medical officer at Walton at a salary of £125, with no extra fees in either case. Dr. Costine wished both officers to be resident, arguing that non-residence means non-fulfilment of duty. Dr. Flynn, however, said there would often be nothing for a resident officer to do. As a decision in favour of residence would have involved the building of a house and a larger salary, the guardians rejected Dr. Costine's motion by 14 to 11 votes.

## Hospital Reports.

### KINGS' COLLEGE HOSPITAL.

*Resection of the bones (after Pirigoff's)—Amputation of the foot.*

(Under the care of Sir WM. FERGUSSON.)

IN the first case Pirigoff's operation was performed at Christmas, and the man left in a fair way to recover. He returned, however, to the hospital a short time since on account of there being a number of open sinuses. Sir W. Fergusson passed a probe completely across the stump from one side to the other; the sinuses communicating he was able to feel bare bone. The wound was then laid fairly open by an incision corresponding to the line of union of the former operation. At this stage Sir W. Fergusson was able to ascertain that although the bone was bare it was not removable, and there was some adhesion between the tibia and astragalus, and he proceeded to saw off a thin slice of the tibia and astragalus. The parts were then brought into accurate apposition, sutures applied, and water dressing.

In the remarks Sir W. Fergusson then made he drew the attention of the audience to the circumstance that the disease was of strumous character, confined to the tibia, and the round hole that was seen in the centre of the piece of bone removed might have been gouged out, but it was better to slice it off. In the history of such operations as this Sir W. Fergusson said that the successful ones were usually recorded—not the unsuccessful. This modern operation has been objected to on account of sinuses remaining, although occurring as they frequently do after amputations. Again, the operation has been objected to as the tissues are slow in getting into a healthy condition. Then, again, the objection as to secondary and even tertiary resections, from his own experience, he knew perfectly well that such operations might generally be done with comparative impunity as there was little fear of any violent inflammation being set up.

Forty years ago in cases of disease of the tarsus amputation was performed either below the knee or above the ankle, and in the former severe inflammation generally followed. There is even at the present day, he regretted to state, a certain amount of reticence among surgeons in reference to failures in these operations. For his part he sees nothing to be ashamed of in recording such cases. Although Nature does frequently assist the surgeon in the cure it not infrequently happens that by her vagaries the surgeons obtain many operations.

In a second case the operation was of a similar character as also in its history. The man had left the hospital with the stump in a questionable position. In the primary operation Sir William had only removed the malleoli, not the articular surface of the tibia—hence, perhaps, the cause of there being no ankylosis. In the present instance he had sawn off a thin slice of the tibia as well as the end of the os calcis. There were, as the class might have observed, some slight bony adhesions which he had broken down

## Correspondence.

### MERCURIAL LOTIONS IN RINGWORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Having read your remarks on Mercurial Lotions in this week's MEDICAL PRESS, I think it may be worth while to state that I have found the application of Liquor Potassæ a cure for ringworm.

Yours obediently,

TREVOR FOWLER, L.K.Q.C.P., L.R.C.S. &c.

### INSOMNIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Perhaps the following somewhat singular case of insomnia, which occurred in my practice some time since, may be of interest to your readers:—

I was called one evening to see a little boy of two years of age, who had recently passed through a rather severe attack of measles, but was now well, and able to be up and running about. I found him suffering from insomnia of a severe character, and threatening to produce absolute insanity, very much excited, pupils much contracted, slight delirium, wandering excited talk, skin cool, no fever, no strabismus. Had scarcely slept for several nights past, and the preceding night had not slept at all. The bowels were purging a good deal. Considering that his excited state and contracted pupils counterindicated opium, I determined on adopting the opposite narcotic, belladonna, which I have found of much use in cerebral excitement; and accordingly applied a plaster of the extract bellad. to the abdomen, and gave æth. chlor. and aq. laur. ceras. aa mist. v. every two hours. He slept for three hours after the first dose of this. I also gave him for the bowels, plumb. acet. gr. j. every second hour. His mother had previously given a chalk and laudanum mixture which I had ordered for a previous occasion for diarrhœa, but on the present occasion it did little good, and decidedly affected his head.

Next day the bowels were something better, but no more sleep, and the delirious excitement much worse. The belladonna had not affected the eyes, though kept on for several hours, and the pupils were intensely contracted. I gave a hot bath, and repeated the æth. chlor. and aq. laur. ceras., but without effect. The child's cries and excitement were incessant, and most distressing; wearing out of the brain and insanity seemed threatening.

His mother now happened to mention to me that he had a short time previously thrown up some bits of meat quite undigested, though it was four days since he had eaten any.

Reflecting on this circumstance I came to the conclusion that mischief of some sort, probably congestion, must exist about the origin of the eighth pair of nerves; and I accordingly ordered a mustard blister to the back of the head, above the nape of the neck.

The effect of this was immediate. In spite of the pain of the blister, of which he complained much, the child was asleep in fifteen minutes; continued to sleep while the mustard was being removed, and for eight hours subsequently, awaking next morning quite quiet, and with all symptoms of excitement removed.

I am, yours, &c.,

Letterkenny, Sept. 23, 1871.

ISAAC ASHE, M.B.

### FRENCH MEDICAL VIEWS OF ALCOHOL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I take my pen to offer you my warm thanks for your kindness in sending me the *Gazette Médicale de Paris*, of 12th ult. You draw my attention specially to its first article, "Hygiène Sociale," by Dr. Roussel, which I have read with deep interest. It is an able production, and should create a profound interest in the minds of those to whom it is addressed: L'Assemblée Nationale. Drunkenness, or, rather, the common use of alcoholic liquors, to which it has special or sole reference, is now, perhaps, the most serious subject of consideration for the statesmen in every civilised country. I use this strong expression deliberately, because the destruction of this poison, alcohol, lies at the present hour at the basis of every great and noble question for the improvement,

—nay, may I not say for the safety,—of the human race. My first impression was to ask you to publish for me an appeal to the medical faculty in Ireland, based on the strong and irrefragable arguments of this brother of theirs, who resides in a land over which, we have long been told, this fiery demon had never been able to obtain an undue influence. Compared with our own country and Great Britain, it has been the popular opinion, and the general statement of travellers, that drunkenness was comparatively little known in France, or on the Continent. This essay of Dr. Roussel's, written with great power, great ability, and with a wonderful knowledge of his subject, completely dispels all such illusions as this. France—Europe—have long been cursed by drunkenness, and laws of the severest character, such as we know nothing of, have been over and over again, and for centuries, enacted for its suppression; and yet, in spite of them all, this terrible tormentor is still the conqueror, and laughs at the idea that his will shall be restrained by any regulations to lessen the mischief he delights in perpetrating.

Having taken my pen to endeavour to carry out my first impulse, I find a difficulty at once in giving a *resumé* of Dr. Roussel's paper within any reasonable bounds. It occupies over eight pages of the Paris medical paper, and every paragraph of it is so much to the purpose, and so forcible, I am fairly puzzled about making any selection. It seems to me that the learned writer has divided his essay into two subjects,—the one a review over some two centuries or more of the mischief, physical and moral, created by alcohol in Europe; the other, the means resorted to for mitigation of those mischiefs, ineffectually, as it seems to me, from his own statements, and from the results as existing in the present day. The first part of his plan has been admirably executed—it leaves naught to be desired; and it is truly a sad and melancholy picture of the steady, the progressive, and the unrelenting ravages of an enemy that has never shown any mercy to the human race. Through all its destructive phases it is traced with a master's hand; and, as the paper was written with a view to assist more legislation on the subject in France, I hope her statesman may at length be able to behold the matter in its true light, which is, that no further tampering with this enemy of our body and our soul, will evince in the future anything but childish inability to deal with a moral and social wrong of such dimensions, that nothing short of its extermination can save mankind from a steady progression on the road to ruin under its influences, which is an evil that has increased in a geometrical ratio, in proportion to population, in every country that has submitted to it.

The second section of the paper is not so satisfactory; it exhibits the waste of argument by learned doctors and lawyers to find the exact amount of the drunkard's criminality, and the amount of punishment that could, with justice, be inflicted on him. The difference of opinions on these points was immense, and made these learned folk—just like unto their successors in the present day—altogether forgetful or unmindful of the christian and correct mode of settling the difficulty by taking the temptation away, and thus avoiding the seeming necessity of ever resorting to punishment for the suppression of crime—the natural and inevitable result of keeping the temptation to it in the way. Dr. R. himself, notwithstanding the multitude of proofs he has adduced, and which lead to an opposite conclusion, seems to think fine and imprisonment may yet be made efficacious. He wisely condemns the cruel punishments of a more barbarous period, such as cutting off the ears, resorted to by one of their kings.

I am not certain about his own views as to suppression of the traffic; but I apprehend he thinks it should be confined to the shop of the apothecary, and used solely for medical purposes.

All his statements as to the actual mischiefs resulting from the use of alcohol—which he conceives to be frequently an irresistible propensity—are familiar to teetotalers in these countries, and in America and Australia; but they come to us with unworked force when we receive them from so unexpedient a quarter.

In the two last paragraphs of Dr. Roussel's essay—which I only venture to quote, out of regard to your space—he seems to have used words to express his convictions as forcible as he could select. They are as follows:—

“Jamais il n'y eut de nécessité plus urgente ni d'heure plus propice. A aucun moment de notre histoire, une assemblée française n'a été appelée à remplir un mandat souverain dans des circonstances plus propres à mettre en évidence la néces-

sité d'agir sur les mœurs par la législation et de donner force de loi à toute mesure capable de contribuer à l'amélioration morale et physique de l'homme.

“L'innovation qui lui est proposée au sujet de l'ivrognerie est à la fois une des plus pressantes et des plus saines qui se puissent introduire ainsi dans notre vie sociale. Quelque hardie que puisse sembler l'initiative, l'œuvre est faite pour tenter les plus prudents et les plus sages, car le temps n'est plus des hésitations et des timidités, lorsqu'il s'agit d'apporter, même dans une mesure restreinte, une amélioration morale plus encore que matérielle, une remède contre une de ces calamités de notre civilisation, qui, après tant de succès dans l'ordre matériel, tant de conquêtes de l'esprit, effrayent et humilient notre génération, autant qu'elles la lèsent profondément en la décimant, en la frappant dans ses forces productrices, diminuant les sources de son bien-être et corrompant les jouissances mêmes qui semblaient devenues le but principal de sa vie. L'œuvre dont je parle réclame tous les concours, et l'Académie me parlera si, en cherchant en dehors du terrain législatif, aucun ne m'a semblé plus nécessaire que le sien. Elle marquera une fois de plus, en le donnant, le rang élevé qui appartient à la médecine, dans les sciences sociales.”

Another essay in the shape of a pamphlet of 47 pages, entitled “Le Démon Alcohol,” has just issued from Paris,—“F. Savy Libraire, Editeur, Rue Hautefeuille 24”—from the pen of Prosser Despine, Docteur en Médecine à Marseille. It was sent me from London a few days ago, and I find it, if possible, more forcible than the one I have just referred to. These two essays mutually confirm the hideous results in France from the use of alcohol, and equally confirm the necessity of prompt and stringent measures in order to save that country from utter ruin. I only venture on two or three quotations from this latter work:—

“A cette heure—la Paris s'empoisonne. Tel est l'état grave, dangereux, et à peu près inconnu, que ce poison détermine sur le moral de l'homme.”

“La majorité de nos citoyens marseillais n'étaient—ils pas des buveurs d'absinthe?”

“Si j'insiste autant sur la suppression de la vente au détail des boissons alcooliques, c'est que l'expérience a démontré l'efficacité de cette mesure. Partout où cette suppression a été pratiquée, une diminution considérable dans les crimes et dans les délits s'en est suivie.”

I cannot venture on any further quotations from this most excellent medical and social pamphlet, and I shall conclude with an appeal to the medical men in these kingdoms on behalf of our own countries, which are as much cursed as any other land by a craving desire for alcoholic liquors; and by an erroneous notion upheld by the great body of our physicians, by their incautions and free use of them as medicine. I have shown in some late letters that, in Ireland, within the century ending 1839, this fierce desire had increased ninety fold, while the population had only increased four fold. Am I in error in appealing to a body of enlightened men to give up, even as a medicine, a poison certainly productive of unspeakable human misery, and not even in the judgment of the entire faculty an article necessary in your pharmacopœia? When such manifest evil results from the use of alcohol, and such uncertainty as to its value as a curative agent, exists, am I not right in assuming it to be the duty of a body of men placed in the responsible position occupied by our licensed M.D's., in the interests of truth and morality, to employ other means for the cure of disease than those which strike at the very root of all that is good in our nature or our lives?

Gentlemen, I beseech you to stand forth as the guardians of public morals in this respect, instead of being, as most of you now are, the seemingly unconscious disseminators of the greatest agent in the production of *ill-health, of sin, and of misery*, among the human race. Your own Profession, honoured as it is among your fellow citizens, would ascend by such an act as I have suggested into a still higher position in public estimation, and by thus striking an effective blow at our demoralising drinking customs, you would confer lasting and unspeakable benefits on mankind.

Several articles, long held in esteem, have been discarded from medical practice. Why should “Le Démon Alcohol” be held sacred?

I remain, Sir, very respectfully,

35 Eccles street, Dublin,  
Sept. 7th, 1871.

JAMES HAUGHTON.

## SPECIAL CORRESPONDENCE.

PARIS IN 1871.

[LETTERS FROM DR. CHARLES R. DRYSDALE.]

To the London Editor of the MEDICAL PRESS.

September, 1871.

STR,—In a former letter I narrated some experiences of mine in Germany in my journey hither, and mentioned a few facts relative to the two sieges which have passed over this remarkable city. It is strange to see my old friends and acquaintances looking very much like what I remember them, in August last year, although they have, many of them, gone through terrible sufferings both in body and also in mind. As to bodily sufferings, these have, however, been very unequally divided in Paris; for, whilst the poorer citizens had to remain sometimes for four or five hours at the mairies before they could obtain a bit of horse flesh, or a little piece of fire-wood, many of the restaurants seem to have had plenty of meat (horse flesh) throughout the whole time of the siege. A poor fellow, a waiter in a restaurant, told me lately that, having a wife, and being in service at the ramparts during the siege, the sufferings he and his wife underwent from the bread during the last weeks of the siege were very great. Neither of them could sleep, and their intestines were inflated and gurgling noises heard in the abdominal region constantly all night through, after eating the bread, which was greatly adulterated with chopped straw. Some of my friends say that perhaps we in London may be burnt some day by those Communists, to whom we now give asylum. In London, however, there is the safety-valve of a free press, and I notice that, when persons with violent opinions are allowed to blow off in words, they rarely enough proceed to violent deeds.

For my part, I cordially detest all surgical methods of solving the difficulties of society by violence, instead of by well-devised plans, thoroughly and fearlessly discussed, before action is taken. I am certain, however, that the French are not inclined to rest with the loss of Alsace and Lorraine. Every one I speak with looks on it as merely a question of a few years, more or less, and then slaughter, they say, must recommence. Even Dr. A. Fournier to-day seemed to regret the small families so universal in Paris at this juncture; since, according to him, *La Patrie* requires an immense amount of "food for powder" at present. I ventured to disagree with this sentiment, and remarked that what France should wish is the healthy and comfortable existence of each man, woman and child, and I think M. Fournier agreed to this argument. It is a curious fact that, at two consultations (out-patient days) at the Hôpital du Midi, when there passed before me nearly 150 patients, I did not see more than two cases of true chancre; all the rest were cases of soft sore, gonorrhœa, or orchitis. This certainly looks at first sight as if the inspection of the prostitutes had recently been productive of some good effect in the diminution of syphilis. On the other hand, most of the patients, women, at the Loureine (and there are 300 beds there) seem to me to be suffering from some form of syphilis, primary or secondary.

For my part, I am inclined to attribute this lessening of infection, to a certain extent, to the fact that there is greater honesty and open-speaking in Paris at present than there has been for many years, under the shameless and immoral government of Louis Napoleon, when, I have heard, that to be a drinker and a frequenter of public brothels was considered by the spies of Government as rather a point in favour of a man, since it proved him not to be one of those rigidly virtuous persons who would object to being bribed into silence by some Government post, or to be what was styled an irréconcilable.

Yesterday, at the Midi, I saw a case of hemiplegia of the right side in a man who had been in the hospital with syphilis two years ago. To-day, I saw at the Loureine a

case of hard chancre of the breast in a young woman, derived from suckling an infected infant. Iodoform is much used at both of these hospitals in the local treatment of soft sores. It is made as follows, according to the apothecary of the Hôpital du Midi: Alcohol, carbonate of soda and water are the ingredients, into which, whilst in ebullition, iodine is dropped, when iodoform is at once precipitated. Its formula is similar to that of chloroform, with the exception that iodine takes the place of chlorine. A. Fournier is loud in his praise of this local remedy in phagedænic chancre; but, at the Midi, the *interne* of M. Mauriac told me that it does not by any means always succeed in such cases in males, or supersede by any means the use of cauterization. There were two cases of soft chancre in the anus shown me, one at the Midi, the other at the Loureine, which is, indeed, a rare lesion in London, and I believe I may say this without any fear of contradiction. About 70 to 80 out-patients frequent the Hôpital du Midi daily, and these are sent thither from most of the other hospitals, which are *supposed* not to treat venereal cases, a rule, I believe, more honoured in the breach than in the observance. But on this point there seems some difference of opinion. The favourite argument for the examination of women here (and not men) is, that it is only women who make a trade or living of their person. When I have replied that the clear answer to this is, that men seem to wish women not to have many ways of getting their living, but the one of being mothers; they do not seem to have thought much about such points, or, indeed, being Catholics, in *name* (for few or none of the able medical men I come across here seem to have *any* real belief in their national church's tenets), they object *in toto*, on supposed utilitarian grounds, to even that facility of divorce, allowed by the laws of England, and seem to think our American cousins quite in a dangerous way, because they are coming back to the old Roman law of facility of divorce. In no country that I am acquainted with, do Catholicism and practical life more contradict each other than here, in France, or, rather, in Paris. Nearly one-third of the births are out of the marriage tie, so that it does seem either that the Parisians require to be convinced: that the Catholic non-divorce system is the best, and to believe in it *practically*, or that this system is quite unsuited to the present inhabitants of this city; and that they would be much more moral in their domestic contracts if divorce were facile, and without stigma attached to it, except in cases where there was deception practised or duties left unfulfilled.

It is curious to see what slight cases are taken into the Hôpital du Midi. Any patient with suppurating bubo, or with orchitis, or with secondary eruptions seems admissible; and many cases of soft sore alone occupy beds in that hospital. Doubtless, this is done mainly on grounds of public hygiene. I noticed that no foreigner is admitted until he has resided at least one month in Paris; and, in the present temper of the Parisians, I should not like to be in the position of any poor German who might be gravely ill in Paris at this moment, and desire to be nursed in a hospital. There is one excellent part of treatment in Parisian hospitals which is much needed in London, *i.e.*, the use of baths of various kinds. Thus, there was a case of scabies among the patients one day, when I was attending to them, in the absence of M. Mauriac; and all that one had to do was to send the patient off to St. Louis Hôpital to be cured in a few hours, instead of trying the slow process in vogue among out-patients in our London hospitals. In another man, with pityriasis versicolor, Dr. Mauriac recommended a bath, containing twenty grammes of bichloride of mercury, which, of course, will cure the complaint much more rapidly than mere lotions applied to small parts of the skin. In balanitis I noticed Dr. Mauriac introduce a thin pencil of nitrate of silver between gland and prepuce. It is a painful, but a very efficacious treatment. Stricture of the urethra does not seem to be very common at the Midi—I see no cases of it there. Dr. A. Fournier was finishing his course of summer

lectures at the Lourcine, and I fortunately listened to the two last, delivered in that admirable manner almost alone to be heard in the clinics of such men as the late Dr. Trousseau and Dr. Fournier. Palsy of the face and muscles of the eyeball, said the lecturer, are seen in the second month of the secondary symptoms, and are readily curable by mercury, or mercury and iodine. The hemiplegias of this period are for the most part curable by using specifics. Probably, there exist certain definite lesions of the nerves to cause these palsies; but *post-mortem* examinations are very rare in this period of syphilis. Certain hysterical and epileptic women have far more frequent attacks of their complaints when they contract syphilis, and the disease may develop of itself into hysteria, with convulsions and epilepsy; in many cases among women there is loss of heat of the body in syphilis—the extremities become cold, and the hand is sometimes like ice. This is not a new observation. Ulrich von Hutten, in the 16th century, noticed these symptoms in his own person. Shivering, followed by sudden heat, is commonly observed; sweating is common at night. Most authors say that syphilis is quite apyretic; but fever is pretty common in the second period of syphilis in women. The intermittent form of fever is pretty common; but the spleen is not enlarged, and the attacks are not so regular as in paludal intoxications. Continued fever is sometimes witnessed. There is also a third form in which the fever is more undecided; but the pulse rises to 110, and the temperature is 38° to 40° Centigrade (40 C = 104 F.); there is headache, and generalised periostitis is common. The fever lasts for a few weeks. Some think that syphilis only causes eruptions in the secondary period: this is an error, for, like all poisons, it acts on the whole of the functions and disturbs them all. The respiration is not much affected, but dyspnoea is sometimes noticed. There is often palpitation of the heart, and great irregularity of pulse noticed among female syphilitic patients, and the sphygmograph shows this most clearly. [Here several diagrams were handed round the class, showing the pulse of syphilitic patients.] Irregularity of the pulse may last for some six weeks. The digestion is sometimes unaffected, at other times it is completely absent; and, more rarely, patients are ravenous. The ordinary portion of bread in the hospital is 120 grammes, and some patients, with syphilis, will devour eleven portions in a day. This exaggeration of appetite has also been noticed in persons poisoned by sulphide of carbon. Pains in the intestines are common in syphilis: colic is sometimes the only phenomenon remarked, with occasional vomiting of food. Diarrhoea is common and obstinate, and only curable sometimes easily, by specifics. Jaundice sometimes is noticed. Loss of weight and strength are common in secondary cases, sometimes extending almost to phthisis. Marasmus occurs sometimes in tertiary cases; and galloping syphilis of this kind sometimes destroys its victim. Here we must use hygiene, and, if mercury be used at all, it must be through the skin, and in very small quantities. Iodide of potassium does not act on the intestines, and may, therefore, be given in such cases. As to the uterine functions, we find that many women become amenorrhœic for many months when suffering from secondary syphilis. Such patients often come to the doctor, thinking themselves pregnant; but, in most cases this is not the fact. Sometimes, on the other hand, metrorrhagia is seen. Depaul speaks of syphilis causing sterility; but this is probably rare, in the experience of Dr. Fournier; but syphilis constantly causes abortions and premature dead-births in the secondary period. An *interne* of the Lourcine made an inquiry on this point at the hospital, and found that, out of five women entering this hospital pregnant, and attacked with syphilis, four aborted, or had premature labours. A patient, cited by the lecturer, had, first of all, three healthy children, and then contracted syphilis from her husband. After this she had seven pregnancies, and seven children were born dead, or had syphilis, and died of it. Whenever a woman aborts frequently, therefore, both her

history and that of the husband should be inquired into. If the parents be then treated by mercury, or iodide of potassium for some time, a healthy child may ensue—even after years of disappointment. Depaul has given many cases of this kind.

In secondary syphilis there is great loss of sensation in many parts of the body. For example, the backs of the hands and the mammary glands are often most wanting in appreciation of pain, which would be severely felt in health. A pin may be run right into the skin of the back of the hand, or into that of the female breast, without being felt, and sometimes there is the same dulness of sensation in parts of the whole surface of the skin.

After this lecture, much of which I doubt not will prove interesting to all who care to hear about syphilis, some ten cases of syphilis in the female were shown to the students, about thirty or forty in number. Dr. Fournier kindly showed me his museum, which is full of interesting wax-casts, &c., of the different curiosities of the hospital. To show that the deeper glands are affected in secondary syphilis, and not only the superficial ones, as Ricord thought, a preparation exists of a woman who died of pneumonia whilst in the secondary period of syphilis, when the glands in the course of the iliac artery were found enlarged, as well as the superficial glands, near Ponpart's ligament. Dr. Fournier also showed me casts of mucous papules in the vagina and on the os uteri, and also of soft and hard sores on the neck of the uterus, of secondary folliculitis, and herpetic syphilides, all admirably done. Mr. B. Hill, I trust, may soon give London students a similar set of clinical lectures, as syphilis in women is little understood in that city in my experience. In a succeeding letter I may, perhaps, give you the substance of Dr. Fournier's lecture on treatment, although, as he threateningly said, "I am going to say *du mal de vous*," in that lecture, perhaps, I should not be the person to report the lecture, with much of which I dissented.

I found the Hôpital Cochin partly transformed into a military ambulance, under the care of Dr. Lefort, who has two wooden temporary hospitals in the garden, in addition to a tent hospital for surgical patients. The wooden wards were put up during the first siege of Paris, when Dr. Lefort was shut up in Metz. His description of the last three weeks' living in that city is heart-rending, Horse-flesh, without either bread or salt, was all the soldiers had to eat, and, I presume, the civilians could not even have had so much as this. Yet, with all this, Dr. Lefort, who has seen many campaigns, *i.e.*, the Crimea, Italy, and the Campaign of 1866, and of 1870-71, declares himself a great partizan of warfare. His reasons for this are, that the nations who are the most fit for war are those where science and literature most flourish; and he asserts that England is, now-a-days, far too fond of peace, and that *we* are likely to be over-powered by some more warlike nation ere long, if we do not more cultivate the art of war.

This is one of the paradoxes of modern times, and, I submit, only remains tenable when men leave out the possibility of all civilised nations gradually becoming able to get rid of that indigence, which is one of the greatest incentives to war, as it is to emigration, and most of the other diseases of society.

Dr. Lefort, you know, is an eminent authority on prostitution, and, last year, came over to London to inquire into our statistics, as compared with French. The Registrar-General informed him that only 4 per cent. of the children born in London were illegitimate, whilst more than one in four of the children in Paris (Lefort says) are born out of wedlock. M. Lefort contended this morning that there would be even fewer marriages in Paris if divorce were as facile here as it is in Chicago, and cited the cases of several eminent Parisian professors of medicine who had never entered into the legal ceremony; but lived for thirty or forty years with the same lady.

According to Lefort, the police of prostitution here is

far too remiss, and should put 15,000 prostitutes under the system instead of 4,000, as at present. He said this morning that there are 40,000 prostitutes in Paris—*i.e.*, women who live entirely by selling their persons; and he quite separated these, he said, from those women who live as above alluded to, maritally with men, whether of the richer or poorer classes. It is extremely difficult for a native of America or of the British islands to come to any agreement on social questions with the French. The fact is that French people have always an idea that the Government, or the Municipality, is to be appealed to in all social difficulties. The genius of England and the United States, on the other hand, I suppose, leads us to think that the Government must *never* be appealed to until all other means of making society enjoyable, or free from crime, have been tried. I prefer *our* theory very greatly to the French, and am convinced that true morality must depend far more on liberty and universal education than on police intervention, which is always rather a vulgar affair, and which frequently causes persons to become criminals and degraded, who otherwise might be excellent and hard-working producers in society.

Dr. Lefort is quite convinced that France must have another war with Germany; but only, he thinks, in some fourteen or twenty years, as it will require all that time, he asserts, to make one million of soldiers in France. So much the better, for in twenty years much may take place, and education both in England and France may make us all less prone to solve our differences by powder and shot. And M. Lefort's opinion, of course, is most valuable, as he has immense knowledge of army affairs.

There was but little of interest in Dr. Lefort's surgical wards, and I did not see anything notable, except a case of artificial anus in an old woman, who came into hospital with hernia too late for operation, and on whom M. Lefort intends to operate by Dupuytren's method. The tent-bed in the garden of the hospital is very charming in summer weather, and quite free from fœtor, although there were cases of suppurating incised wounds in it quite fit to produce much fœtor in ordinary wards. In winter I suspect, however, that it must be too cold, and not equal to the wooden huts in the garden. Here there were some patients wounded in the *jours d'enfer* of the Commune.

Those who would see the horrors of war in Paris should proceed to Auteuil, thence to St. Cloud, and returns by Courbevoie and Neuilly, and if they still think that war is a necessary of human existence, all I can say is, that they are made (which may easily be) of sterner stuff than myself. To hear too of the thousands of men, women, and children shot down by the regular troops is quite enough to cause persons without faith in science to despair of the future of the race. The Palace and town of St. Cloud were both entirely burnt by the Prussians—some say after peace was established; and the mass of poor person's houses which have been knocked down near Auteuil, Neuilly, &c., is quite indescribable. The loss of public buildings is a terrible thing; but the suffering caused to individuals by the loss of their little property has been, I daresay, much more painful. And yet it seems to me as if food, clothing, and lodging were all rather cheaper in Paris this year than in previous seasons; although the loss of house-room has been so large. So rapidly does industry clear away the effects of all catastrophes in modern times. I have received a great number of *brochures* from Drs. Fournier, Mauriac, and others, and may endeavour to extract something from the rich mine thus within my reach in my next letter.

## OBITUARY.

SAMUEL SOLLY, F.R.S.

THIS much esteemed surgeon died on the 24th ult. His death was in a sense, sudden, but he had been out of health for a considerable period. He had twice been

Vice-President of the Royal College of Surgeons of England, and would have been President, but for the recent turn in college elections. Many regretted that he should have been made as it were a necessary sacrifice in the progress of the collegiate reforms which on a small scale have been effected.

The writer well remembers the last few times he had the pleasure of a professional chat with the veteran surgeon of St. Thomas's Hospital, on one of which he received from his hands, the volume of "Surgical Experiences," which is so well-known and the promise of the new edition of his great work on the "Brain" which he hoped to be able to bring out. It was to be otherwise, and we were to lose this amiable and accomplished gentleman. Mr. Solly possessed a refined taste, and was himself an artist. His own works were illustrated by engravings, which were drawn on wood by himself, and his water-colour pictures have been in the Royal Academy.

One of his sons, Mr. Edwin S. Solly, follows his father's profession. We wish him as long and useful a career as his well-beloved parent. Other children and a widow also survive, whose natural grief at their great loss, may perhaps be somewhat assuaged by the reflection, that throughout a long and honourable career as a hospital surgeon, Mr. Solly retained the esteem of those most capable of estimating his sterling worth.

G. CURSHAM, M.D.

ON Saturday week, September 23rd, full of years and honours, there passed away at the age of seventy-five, George Cursham, M.D. Paris, F.R.C.P.

Long will Dr. Cursham be mourned and his memory affectionately cherished by those who were admitted to the privilege of his intimate acquaintance.

Dr. Cursham's high principle and unflinching rectitude, combined with his clear judgment, made him highly respected by his professional brethren, who must feel that one has gone forth from amongst them, whose place will not easily be filled.

Dr. Cursham was, for many years, physician to the Brompton Consumptive Hospital, and to the Asylum for Female Orphans, he was also for some years Secretary to the Medical Chirurgical Society, and held up to the time of his death, the post of Inspector of Anatomy to the Provincial Schools.

MR. ROBERT P. CURRAN.

WE regret to announce the death of Mr. Robert Pilson Curran, youngest son of Waring Curran, Esq., which took place on the 22nd September, at the residence of his brother, Dr. Henry Curran, Blessington street, Dublin. Death resulted from heart disease, which none who knew him had the slightest idea of existing in his case. He had a short but useful life, and had gained the highest prizes awarded to ability and industry in the Dublin medical schools. For his care of, and attention to, the poor, he was specially requested to continue in residence at Mater Misericordiae Hospital, on the expiry of the usual term of residence, which he readily complied with. The deceased was only in his twenty-second year. Mr. Curran had only lately returned to Dublin from Mansfield Woodhouse, where he had been assisting his brother, Dr. J. Waring Curran in practice.

Only a few weeks back, several interesting cases, met with in the Mater Misericordiae Hospital, from the pen of Mr. R. Curran, were published in the columns of the MEDICAL PRESS AND CIRCULAR.

THE new number of the *Practitioner* opens with a paper by M. Labbe, of St. Antoine Hospital, Paris, in which that able surgeon gives some of the points of practice observed during the siege.

## Medical News.

**Apothecaries' Hall of London.**—At a Court of Examiners held on the 28th ult., Messrs. Shrofield Elan (Guy's Hospital), and John Mountain, of Wise's hill, Cork, were admitted as licentiates of the Society of Apothecaries, and the following passed the primary professional examination—viz., Messrs. William Edward Bennett, of Guy's Hospital; John Evans, of the London Hospital; and Edward James Nix, of the Charing-cross Hospital.

**A Working Men's Hospital for Birmingham.**—The Baroness Burdett Courts is expected to lay the foundation-stone of the Working Men's Extension Wing of the Queen's Hospital at Birmingham, about the end of this month. A sum of £5,000 has been raised in three years by the periodical contributions of 20,000 workmen in the principal factories of the town. The amount contributed is highly creditable to the working men of the town, as it will be the first hospital in the kingdom erected under such auspices.

**Malpractices in New York.**—"Thousands of human beings are murdered before they have seen the light, and thousands upon thousands of adults are irremediably ruined in constitution, health, and happiness. So secretly are these crimes committed, and so craftily do the perpetrators inveigle their victims, that it is next to impossible to obtain evidence and witnesses. The men and women engaged in this outrageous business are, with few exceptions, the worst class of impostors; very few have genuine medical diplomas. The female practitioners generally have been nurses or midwives. Almost invariably they are in partnership with a man 'doctor,' and are entitled 'madame,' or in some cases 'doctor.' Lady patients, of course, prefer calling upon a 'madame' in delicate cases, and are willing to converse freely with her. . . . They compound and prescribe the most dangerous drugs, with reckless disregard of human suffering and life, and venture upon operations that are always hazardous, and not infrequently fatal. The case of most recent notoriety was that of Dr. Evans, who was recently convicted and sentenced in the Court of General Sessions to five years' imprisonment in the State Prison. In his horrible den were found evidences of guilt of the most conclusive nature. Human flesh, supposed to have been the remains of infants, was found in barrels of lime and acid, undergoing decomposition. He came here from Scotland about twenty years ago, with no medical education whatever. Stubborn energy, active perseverance, and undaunted boldness, appear to have forced his guilty success. Shameless advertisements of 'relief for ladies in trouble' are admitted into certain journals, and it is said that this man advertised to the extent of 1,000 dollars per week, and received a daily average of 400 letters, most of which enclosed money for pills. A gentleman recently called at an office in this city, and was ushered into a room, the door of which was closed and locked. 'Are you Dr. M.—?' was asked. 'Yes; what can I do for you?' was the smiling reply, accompanied by a keen penetrating gaze. 'I called to ascertain if you could relieve a lady of a physical difficulty' (describing the case). 'I can, sir.' 'Without danger?' 'Yes, sir—have had thousands of cases: have them all the time, and never had any trouble at all.' How long will it take, where will she be treated, and what are the terms? 'A week or less, and I can find accommodation, up town, very elegant, and the terms will be reasonable. But I must see the lady first before I say anything further.' This man was formerly a printer; but Madame R., his reputed wife, induced him to abandon that occupation. At her house, at a door labelled 'office,' a lady and gentleman recently called. They say:—'We were ushered into a small, darkened room, and had just sat down when the madame entered herself.' 'Well, and what can I do for you?' she asked. 'Can you relieve a lady of a physical difficulty?' 'That depends upon circumstances.' A suppositious case was stated, and she promptly replied,—'There will be no difficulty about that. Of course such affairs are expensive, you know. The charge will be—' Just then a sharp, quick rap was heard upon the door, and a voice from without exclaimed, 'Ma, I want to speak with you a moment.' The madame then retired, and we could hear a brief but rapid colloquy. The next instant she returned, and, in evident trepidation, said,—'I can sell you some pills, but really we do no other business. We have had so much trouble about trouble about these matters we don't take any more risks. In

all the six years that we have lived in this house a stranger has never slept under the roof—none, in fact, but our own family.' Other parties who have been there had a different experience. Only the police authorities have anything like an adequate idea of the gigantic dimensions of this evil. Every day adds new indications. That the number of murders from this cause is not generally known is easily accounted for. All the parties interested have the strongest motives to unite in hushing up the scandal. An advertisement has for a long time appeared from Madame G., female physician, who 'guarantees relief to all female complaints—pleasant rooms for nursing;' and there is a like advertisement from Dr. G. They have a house capable of accommodating about twenty patients. A lady and gentleman recently called there, and thus relates what passed:—'Madame addressed us, 'My dear friends;' she said, 'we can do what you hint at. I understand the case. We have had hundreds of them. Poor unfortunate women! How little the world knows how to appreciate their trials. We think it our mission to take them and save them—a noble work it is, too. But for some friendly hand like ours how many, many blasted homes, scandalised churches, and disorganised social circles there would be. Why, my dear friends, you have no idea of the class of people that come to us. We have had senators, congressmen, and all sorts of politicians bring some of the first women of the land here. Many, very many, aristocratic married women come here, or we attend them in private houses.' What are your charges, Madame? '300 dollars cover all expenses, and we see the patient through—unless it occupies more than a week. Then we charge an extra medical fee and board money.' 'What about the child?' 'Well, we adopt it out in good hands. 100 dollars extra is our fee for that.' 'But if not a child, what then?' A quick rolling and flash of her glittering black eyes, a sprightly nod of the head, a finger placed on the lips, a knowing look, and 'sh-h!' was the pantomimic reply. 'We understand every branch of our business' she exclaimed, with peculiar emphasis. . . . The mails go burdened with the circulars of such people, and come laden with money enclosures for 'pills,' 'drops,' and other vile humbugs. The best home firesides in the land have been invaded by these advertisements, either in the newspapers or in letters. To what a frightful extent this outrage is rapidly increasing few can realise.'—*New York Times*.

### Rapidity of Conduction in Motor Nerves.

HELMHOLTZ and DAXT (*Monatsbericht der Berlin Acad.*, 1870, 184), in their new researches on the rapidity of conduction in motor nerves, use the same method as before, the arm being immovably fixed in plaster of Paris, and the median nerve irritated first above the elbow and then at the wrist. The contractions which are thus produced in the muscles of the ball of the thumb are registered by Marey's myograph. Instead of using a revolving cylinder, the curves were registered by Fick's plan on a glass plate attached to the bob of a pendulum, which in the middle of its swing caused a spark from an induction coil to irritate the nerve. They found that a higher temperature increases the rapidity of conduction in human nerves as well as those of the frog. Conduction is quicker in the upper than in the forearm, and this seems to depend on unequal conduction in the nerves themselves independently of any difference between the temperature of the parts. When the nerve was irritated by shocks quickly following one another, the contraction of the muscle was no more powerful than when only one was employed, unless an interval of more than one five-hundredth of a second intervened between them. Constant currents, especially descending ones, readily produced tetanus in the muscle, during which oscillations lasting  $\frac{1}{100}$  of a second took place in it.

Placc (*Plüger's Arch.*, iii. 424), in a research undertaken along with Van West, found by Helmholtz's method the rapidity of conduction in motor nerves to be 50-60 metres in a second, the mean being 53, a much greater rapidity than Helmholtz had found in motor nerves (33 metres), and very nearly the same as that he had found in sensory ones. When the irritation was applied high up, near the coraco-brachialis, they found a rapidity of 35-26 metres. The rapidity of conduction in the forearm they found to be much greater than in the upper arm, it being 56-62 metres in the former, and only 12-14 in the upper.—*Jour. Anat. and Physiol.*

## NOTICES TO CORRESPONDENTS.

**POT OR KETTLE**—You are quite right. The squabbles from contemporaries are silly. The *Association Journal* has no pretence whatever for claiming any right of priority to news. It does not know of appointments any sooner than the other journals. The one named was announced by dozens of papers before Saturday week.

The *British* lacks courage to name the journal it accuses of "continuous criticisms of its sayings and doings." Awful crime!

The insinuation about "general appropriation" of its patent right in news or public reports in an "unceremonious manner," comes with a bad grace from the *British* (save the mark!) journal, so soon after the *Lancet* convicted it of taking word for word, a translation from the pages of an American contemporary, and palming it off as its own leading article.

Neither of these journals has disdained to use our columns, or to serve up in a different form, months afterwards, what had originally appeared in our pages.

Dr. R. E.—We are very much obliged for the information and the promise in yours of the 25th of Sept., and shall not forget. In a short time the paper you want shall be posted to you.

## ARMSTRONG MEMORIAL FUND.

To the Editor of "The Medical Press and Circular."

Sir,—I am requested by the Committee of the above Fund, to beg permission through your widely circulating Journal, to announce to such Members of the Profession throughout Ireland as may wish to subscribe to the monument about to be erected to the memory of the late Dr. Armstrong, and have not yet done so, that the subscription list will close on Saturday, 7th October.

I am, Sir, yours faithfully,  
W. H. HOLMES, Hon. Sec. to Committee.

35 South Mall, Cork, Sept. 29th, 1871.

"The Sitting Posture in Prolonged Catheterism." By R. Hanslip Sers, M.R.C.S. Received.

"Martyrdom." By an Army Surgeon. To hand.

Mr. L. G. C.—Not received until Tuesday, when the Journal was on the press. In our next.

Dr. H. C. B.—See previous reply.

Dr. G. H. PHILIPSON.—Next week.

## BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Pulmonary Consumption. By C. J. B. Williams, M.D., F.R.S., and C. T. Williams, M.A., M.D. London: Longmans, Green, and Co.

The Use of the Ophthalmoscope. By Thomas Clifford Albutt, M.A., M.D. London: Macmillan and Co.

Complete History of the Welsh Fasting-Girl. By Robert Fowler, M.D.

Fistula and other Diseases of the Rectum. By W. Allingham, F.R.C.S. London: J. and A. Churchill.

Boston Medical Journal; Nature; The Pacific Medical Journal; The Anti-Vaccinator; L'Union Medicale; The Journal of Mental Science; Le Mouvement Medical; British Journal of Dental Science.

## VACANCIES.

Liverpool Northern Hospital. House-Surgeon. Salary £100, with board.

Marlborough Union. Medical Officer. Salary £50, exclusive of fees.

Tiverton Union. Medical Officer. Salary £25, with midwifery fees.

York County Hospital. House-Surgeon. Salary £100 per annum.

Cornwall Lunatic Asylum. Assistant Medical Officer. Salary £50.

Warrington. Officer of Health for the Borough. Salary £100.

## Births.

NORRIS-CANE.—On Sept. 21st, at Mullinavat, Co. Kilkenny, the wife of Dr. J. B. Norris-Cane, of a daughter.

## Marriages.

DOBREE—BRIDGE.—27th ult., at the parish church, Wellington, Samuel Dobree, Esq., of Wellington, Somerset, to Mary Mitford Tozer daughter of S. Franklin Bridge, Esq., M.D., of Old Court, Wellington.

FITZ-GIBBON—FOOT.—On the 26th Sept., at Monkstown Church, Co. Dublin, by the Rev. Benj. Gibson, Chaplain to the Rotundo Hospital, assisted by the Rev. Ronald McDonnell, D.D., Rector of Monkstown Church, Henry Fitz-Gibbon, M.D., M.Ch., T.C.D., and L.M., of the Rotundo Hospital, to Meta Adelalde, youngest daughter of William Foot, Esq., of Belgrave square, Monkstown.

## Deaths.

ALEXANDER.—On the 23rd ult., Gervase Alexander, M.D., of the Haymarket, aged 65.

EVANS.—On the 13th ult., G. F. D. Evans, M.D., M.R.C.P.L., of Shrewsbury, aged 81.

HARRIS.—On the 22nd ult., at Bath, Charles A. Harris, M.R.C.S.E., aged 63; for forty years a medical practitioner in that city.

MORGAN.—On the 23rd ult., John Flower Morgan, Surgeon, of Lamb-ridge place, Bath, aged 86.

VALLANCE.—On the 22nd ult., at Stratford, Essex, James Thomas Vallance, M.D., F.R.C.S.E., of Villetto, Broustains, Kent, aged 63.

WRIGHT.—On the 22nd ult., accidentally drowned at Festiniog Falls, Merionethshire, Wm. Henry Wright, M.R.C.S.E., L.S.A.L., of Clapton square, London, younger son of the late R. J. P. Wright, Esq., of Clapton.

Established 1848.

## PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY, LL.D., M.R.C.S., F.L.S.,  
&c., (King's Coll.), and Author of VIA MEDICA,

Has always upon his books a large number of desirable investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services repdered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays, from 11 till 2.

PRACTICES AND PARTNERSHIPS NOW OPEN for negotiation (in addition to those advertised in Dr. Langley's List, (which is sent post free on application).

Y 306. In a pleasant Country Town there is an unusually favourable opening for the succession of an active gentleman, to a large and lucrative PRACTICE. Present incumbent having accepted a Partnership in London, will secure the introduction on very easy terms. There is an immediate Practice of £300 a year, with appointments yielding £30. Very convenient house at a low rent. There is great scope for increase. Premium £100, part of which may be left on security.

Y 304. WEST-END. Held by the vendor ten years; the annual value of the practice is, on an average, upwards of £700 a year, of which, about £300 is taken in ready money. The house is situate in an important thoroughfare, contains fourteen rooms, garden, &c., on beneficial lease. There is an open surgery connected with the practice, the proceeds from which could be largely increased.

Y 300. PARTNERSHIP in a MANUFACTURING TOWN, where there is ample scope for increase. The present receipts are over £800, of which £300 are derived from contracts with public works. One horse and carriage sufficient to work the practice; the present incumbent desiring to secure an active gentleman's co-operation, is willing to accept £500 for the half share, part of which may be paid by instalments. The incomer could live very inexpensively, and need not be a married man.

Y 298. FIRST-CLASS PARTNERSHIP in a WEALTHY TOWN, situate within fifty miles of London, and accessible by rail. The connection is very old established, and has been held by the incumbent for forty years. The increase is upwards of £1,000 a year, and the patients consist of gentry clergy, farmers, and tradespeople. All appointments have been declined, but could be obtained by the junior, if desired. Midwifery fees, two guineas and upwards, except a few cases by the assistant, at £1 1s. The incoming partner must be doubly qualified, of un-exceptional character, and well acquainted with his profession. Terms based on two years' purchase.

DR. LANGLEY'S Quarterly List of Selected Practices, Partnerships, &c. Quarterly List for October is now ready, free by post on application.

SYR. FERRI PHOSPH. CO. (AMERICAN.)

## PARRISH'S CHEMICAL FOOD.

PREPARED BY PARRISH, OF PHILADELPHIA,

and imported by his **SOLE AGENTS**

P. AND P. W. SQUIRE, 277 OXFORD STREET, LONDON, W.

For convenience and security, this preparation is supplied in 4oz, 8oz, and 1lb. bottles.

Each Bottle bears the name **SQUIRE** on the Seal and Label.

## BOILEAU AND BOYD,

WHOLESALE DRUGGISTS AND MANUFACTURING CHEMISTS,

DEALERS IN DRUGGISTS' SUNDRIES,

MEDICAL APPLIANCES, AND SURGICAL INSTRUMENTS OF EVERY DESCRIPTION.

Great Coat) WIND AND WEATHER PROOF, manufactured

by Kenny and Owens, Merchant Tailors, 54 Dame st.,

Dublin The 16s. Trowsers House.

COOKESTOWN HOUSE, INSTITUTED FOR

## THE MEDICAL TREATMENT OF THE INSANE OF BOTH SEXES.

This highly respectable Man-sion in no respect resembles, either internally or externally, what is usually known as an Asylum.

The Demesne, Conservatories, Graperies, and Grounds are unusually extensive, and in good condition.

There are Billiard Tables for both sexes, with indoor and outdoor amusements, including Vehicles.

Cookestown House is within three miles of Carrick-on-Suir Station, with a like distance from Fiddown, both on the Waterford and Limerick Lines, and in connection with the G. S. & W. and Kilkenny Lines.

For terms, and Form of Admission, apply to the Resident Physician.

JOHN PEPPARD, M.D. &c.

Cookestown House, Piltown, co. Kilkenny.

MEDICAL DEBT RECOVERY OFFICES,

13A, Great George street, Westminster, S.W.

MR. W. T. PEACOCK, DEBT COLLECTOR and ACCOUNTANT, begs to intimate that he continues to devote his personal and careful attention to the RECOVERY of DEBTS.

MEDICAL PRACTITIONERS, in TOWN or COUNTRY, by availing themselves of Mr. PEACOCK'S services, will ensure an economical, prompt, and efficient mode of recovering their outstanding accounts.

Terms and references on application, or sent post free.

## The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

|                             |        |
|-----------------------------|--------|
| Seven lines and under ..... | £0 4 0 |
| Per line afterwards .....   | 0 0 6  |
| One quarter page .....      | 1 5 0  |
| Half-page .....             | 2 10 0 |
| One do. ....                | 5 0 0  |

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

# The Medical Press & Circular.

## Original Communications.

### ON THE PROPOSED CHANGES IN THE NOMENCLATURE OF THE PHARMACOPEIA.

By CHARLES R. C. TICHBORNE, F.C.S., M.R.I.A., &c.,  
Chemist to the Apothecaries' Hall of Ireland.

PROFESSOR ATTFIELD has lately proposed that certain changes should be made in the nomenclature of the "British Pharmacopœia." That the modern notation should be used only, that the terms employed should coincide with that notation. Thus in the present Pharmacopœia, two notations are employed but only one nomenclature, therefore the framers of that work gave preference to that notation which harmonised with the old system, this however is nearly now obsolete.

Professor Attfield's "Pharmaceutical Chemistry" has made such rapid progress in public estimation, that it may be considered to have become the medical and pharmaceutical test book of chemistry. Its reputation is not one iota in advance of its merits, and as the originator of such a work, Professor Attfield's words come with even more force than they otherwise would. The general tenor of his recommendation is to the effect that we should retain the Lavoisierian mode of nomenclature, but substituting the metallic names for the alkalies and alkaline earths. Thus we should say sulphate of sodium, sulphate of iron, carbonate magnesium, instead of sulphate of soda, sulphate of iron, or carbonate of magnesia—also that we should discard the old atomic weights and use the new atomic weights alone, with all this, I as one humble worker in the field of science heartily agree. Fourteen years ago I advocated these new fangled ideas as they were then termed, and have consistently used them in practice. So little were such views entertained at that time, that with one exception there was not another chemist in Dublin who even acknowledged

the probable correctness of such a system. What a change has been effected in these fourteen years.

This was the system used by Aug. Hofmann, when the writer was at the College of Chemistry, and it will be perhaps in the memory of some of the gentlemen present, that exactly a similar system is used in his, Dr. Hofmann's, "Report on the Exhibition of 1862." In speaking of this matter in the introduction to that Report, he says, "The symbolic notation employed in this report, requires a few words of explanation here, and perhaps also of justification. It differs from the notation still in use, only by the doubling of the equivalents usually assigned to oxygen, carbon, sulphur, and a few other elements, slight, however, as this change is, it suffices to alter materially the aspect of many formulæ, and to those who still adhere to the old notation, it may give a little trouble which the reporter would willingly have spared them; for this reason, indeed, he hesitated a good deal before deciding to employ the modified notation. To this decision, however, he was ultimately brought by the reflexion, that the modified notation is essentially necessary to represent with the requisite clearness and precision the vast and daily multiplying class of substitution changes, and that on this ground only, if on no other, the double equivalents must ere long come into universal use." "The author then uses the terms carbonate of sodium, sulphate of ammonium, &c. Dr. Attfield wishes to substitute a similar system for the one used in the "Pharmacopœia," such a system that whilst giving due prominence to all the most firmly established theories of modern chemistry, it also does away with such inconsistencies as calling one salt the sulphate of the oxide, and another salt exactly framed upon the same type the sulphate of the metal. It enables us to view all these salts as constructed upon one given framework. But outside this it does not go, and when from time to time extreme terms are introduced for the coining of special or extreme theories they must not be considered in any system intended for general introduction, but should be strictly confined to the writers of original research. Therefore the fraction of any science necessary for the furtherance of any other art must harmonise with the knowledge, to which we have attained, thus far must we go and no farther. It is for this reason that

I agree so thoroughly with what Dr. Attfield has advocated, I might perhaps object to a few of the changes which he has proposed, but really these things are so much a matter of taste and his paper has been so well and ably discussed, that I do not consider this the time or place to enter into these small matters. Dr. Attfield makes use of a paragraph which seems to lay down a principle, which hardly agrees with the practice of his own paper, great prominence has been given to the supposed principle by some of the reviewers. Thus an excellently conducted one the *Chemist and Druggist* says, "Clearly he has proved his point, and shown that chemistry and pharmacy, though branches of the same science have distinctive characters, and that it will be for the mutual advantage of both to adopt a nomenclature of their own." Now I must dissent from this view, a nomenclature is only a system for the conveyance of facts, it is not to be supposed that we could have two nomenclatures harmonising equally if at all with facts. As well might we some years since, when the avoirdupois ounce was substituted for the troy weight have said, that as the division of the pound gave 437.5 gr. to the ounce which was inconvenient, that pharmacy should have an arithmetic of its own, and that one and one in mathematics made two, but in pharmacy they should make three. No? We must have the same chemistry for the philosopher, the same chemistry for the pharmaceutical, and the same chemistry for the medical man. In other words, as near the truth as the science of the day will take us and nothing but the truth. It was for this reason that I saw with pleasure, that Dr. Attfield had hit hard at such terms as acidum arsenicum which, from a chemical point of view, is radically wrong. We are informed that there is not likely to be a new edition of the "Pharmacopœia" for some time, but I am quite convinced that when it does come we shall have the new atomic weights, and a binary notation, and a nomenclature in conformity with the new system alone. Thus will Dr. Hofmann's prophesy be fulfilled as regards another important branch of practical chemistry.

One of the proposed changes is, that the names should convey more accurately the actual chemical composition as by analyses. Thus it is proposed that the term oxyacetate of copper should be used for verdigris. The few cases met in the "Pharmacopœia" similar to the above one, are I think better got over by using trivial names just as we in the "Pharmacopœia" specify a certain well known quality of carbonate of calcium as chalk, although we have at the same time the pure article as far as ordinary chemical processes will give it. In fact, it is hard to say how the excess of oxide of copper found in the verdigris can be considered any more or less of an impurity than the silica found in the chalk. I am of opinion, that we are rather too much inclined to view chemical decomposition as much too sharp and definite, and thus in some instances to be too particular. Because we see a voluminous precipitate tumble on adding hydrochloric acid to nitrate of silver, we are naturally predisposed to consider it as a perfect precipitation of all traces of silver. But although such is practically the case, as far as our balances go, it is really merely a re-arrangement of the balances of the forces at work, and it is much more probable that this precipitation is in reality imperfect, and that it is merely a partitioning of the elements. But we have not instruments delicate enough to determine this. In nature there are no such things as very sharp and hard lines, and when we get a basic carbonate of magnesium on mixing carbonate of sodium and sulphate of magnesium, it is merely that some of the carbonic anhydride is partitioned off by a new arrangement of the forces. That the point where this partitioning lies, depends upon many circumstances as temperature, &c.; and we get a precipitate of carbonate of magnesium containing variable quantities of oxide of magnesium. Under such circumstances, should we not view the oxide simply as an impurity not necessary to remove, and merely state in the "Pharmacopœia," that amongst its characteristics carbonate of magnesium contains variable quantities of oxide.

I think that the great difficulty in the perfect acceptance of the new notation in pharmacy is that, most of the medicinal licensing bodies do not make it compulsory that the candidate should answer in the new notation, but leaves it optional. As long as it is so, it will never be perfectly adopted in pharmacy. The latter must sail in company with the practice of medicine. Now there are a much larger number of medical students registered than pure pharmacians. With the pharmacien the acceptance of the new notation is easy. Chemistry is his principal and most difficult study, he must have both a theoretical and practical knowledge of it, or he is no pharmacien, and there is only just a little more trouble in learning the new system. But chemistry hitherto has formed but a moiety of the medical student's study, and that moiety is looked upon as a matter of secondary importance. In such a case, if the student is presented with two roads, he will very naturally take the shorter one.

My only object in bringing this subject before the Conference, is to urge the paramount importance of a strictly scientific nomenclature, which point I do think has not received due consideration. As simple as we like, but let it be as near the truth as we can go. Let us have as little change as possible, but when it does come, let it be to keep pace with the progress of science. There is no danger of Macaulay's New Zealander appearing on London Bridge for some generations to come, therefore there is a long period before it for pharmacy to assert itself in this country. It is to be done by our ever bearing in view

"That banner with the strange device, Excelsior."

#### RUPTURE OF THE PERINEUM.

By J. McKEOGH, L.R.C.P., &c., &c., Thurles.

On the night of the 26th March last I was called on to attend, in her first confinement, Mrs. C—, who was stated by some of her friends to be aged thirty-five, by others forty years. She lives at or about five miles from here, and is the wife of a small, yet comfortable, farmer. I arrived at her house by 10.30 p.m. She was first taken ill on the previous day. I found her very restless—making very loud complaints of the severity of her sickness—pulse, about 110; bowels had been cleared out by oil; no water in bladder; pains rather strong, but expulsive force misdirected.

I made a vaginal examination—found the soft parts quite cool, and in every respect normal; pelvis, narrow in transverse measurement; articulations, as far as I could judge, and from her age, were non-expansive; found the head presenting in the first position. When I entered the room she was attended by three very old and very ignorant women, such as are generally found with such class in country practice. I used no ergot, and after waiting three hours, when I found no progress was being made, I applied the forceps (no chloroform was used), having first placed her transversely in the bed, hips projecting over its edge. I then directed one of these old women to guard the perineum; but she, from a feeling of delicacy, as well as I could interpret it, replied that "she did not like the job." However, she, after some persuasion, remained in the position I placed her, but gave very little aid indeed. The head was so tightly jammed in I had to use a good deal of extractive and compressive force. I soon, however, succeeded in delivering a male living child. The head was large, the bones being very much ossified and not mouldable; but, unfortunately, there was an entire rupture of perineum, sphincter ani, and a little of the recto-vaginal septum notched. I did not attempt to interfere with the rupture then on account of the blood that was being discharged, and for several days afterwards; but on the tenth day after I operated. The previous night a purgative was given to act on the bowels.

On the 6th of April I operated, my only assistant in everything being an old woman such as I described above. No chloroform was used. When I had got her into a

position, resembling as closely as possible the lithotomy one (for I had to operate while she lay in her bed, a very old fashioned one with a circular tester, and the room moreover was very small), and after having shaved the perineum, I then well pared each edge of the wound—cutting from below upwards—and next introduced deeply two quilled sutures (the perineum was in this case short), of dentist's silk, and five of the continuous, or glover's, sutures consisting of silver wire. After all oozing had ceased I then applied collodion thickly over the wound, and having, as tightly as could be conveniently borne, bound the thighs with a bandage, I fixed her in bed and gave a pill of *one* grain of opium, and to be repeated every sixth hour.

*April 7.*—To continue pills, and to have six ounces of port and beef-tea during the day. Is doing well in every respect.

*April 8.*—Wound appearing well; health good; to continue pills and dietetic treatment as before.

*April 9.*—Not seen, being Sunday, and had to attend other pressing calls.

*April 10.*—Removed quilled sutures to-day; suppuration had set in along their track; wound united at bottom; bowels moved; it would, I see, have been better if the sutures had been removed the day previous; pills and other treatment as before.

*April 11.*—Going on well; appetite good and sleeps well; pills and other treatment as before.

*April 13.*—Could not find any of continuous sutures, for they were buried in the tissues; doing well; treatment as before.

*April 14.*—Complaints of flatus passing from rectum into vagina. On examination I find there is a small aperture between them, such as would nearly admit the point of small finger; applied to it solid arg. nit.

*April 17.*—Bowels moved; pills and other treatment to be continued; applied solid arg. nit. to recto-vaginal aperture.

*April 19.*—Removed some of sutures; suppuration has set in in their track; applied a mixture of equal parts of acid carb. and glycerine.

*April 23.*—Wound looks well, and filling up with healthy granulations; health good; pills and other treatment to be continued; is very irritable on account of being confined to bed, and insists on getting up.

*April 25.*—Removed remainder of sutures; applied mist. acid carb. et glycer.; bowels moved; to continue pills, &c.; becoming more impatient, and demands to be allowed up; applied solid arg. nit. to recto-vaginal aperture.

*April 27.*—Bowels moved; wound filling up rapidly; no application used; pills and other treatment as before. Most anxious to be allowed up.

*April 29.*—Recto-vaginal fistula all but closed; wound nearly healed; applied to it a solution of arg. nit.  $\zeta$ ss. ad aq. dist.  $\zeta$ ij.; would not allow mist. acid carb. On account of pain caused at last application; bowels moved; to continue pills and other treatment. Requests to get up.

*May 2.*—No application to recto-vaginal fistula or wound; to continue pills and other treatment; general health quite good. Applied to wound a soft pad and a T-bandage, and is to get up to-morrow.

*May 6.*—Recto-vaginal fistula quite closed; wound all but filled up to a level with surface. I have been told my services would be henceforth dispensed with; and had not seen Mrs. C. till the 27th July last, when I found her in her usual good health, and attending to her usual domestic duties; and after making a minute examination of all the parts engaged in the operation, I had the great pleasure to find that all were restored to their perfectly normal state, and only the slightest cicatrix remaining.

P.S.—I did not divide the sphincter ani on each side of the coecyx, as is recommended in Erichsen in these cases.

## THE TREATMENT OF ECZEMA.

By J. L. MILTON,

Surgeon to St. John's Hospital for Skin Diseases.

*Continued.*

3. *A Course of Steel.*—When the discharge is profuse, when even in the dry form eczema has existed many years, and in all cases when improvement has come to a standstill, I would advise a course of steel—a remedy which, in my hands, has proved of more use against eczema in this stage and under these circumstances than any other I have tried, or seen tried.

Steel wine, carefully prepared, and given in doses of one or two drachms two or three times daily, will remove most cases of eczema during the first year or two of life. The wine should be procured from a really good chemist. I have tasted specimens of it so harsh and acid that I could not wonder at children disliking it. Some of them seemed to me compounds of rusty iron and the worst kinds of acid sherry. A very agreeable preparation is made by Messrs. Bell, of Oxford street. When children have passed this age steel wine requires to be given in large doses to produce any effect, and therefore becomes rather an expensive medicine, especially in hospital practice. Here the saccharine carbonate may be substituted, two or three grains being given twice a day. Should its effect not correspond to the surgeon's anticipations, I should recommend that the tincture of the muriate, in doses of five to fifteen minims three times a day, sweetened, be given instead. In hospital practice the acid solution of iron, previously mentioned in these papers, from three to five minims three times a day, though not quite so pleasant, is quite as useful as the tincture.

From puberty to the decline of life I would most decidedly recommend the tincture of the sesqui-chloride, or the acid solution just alluded to, always accompanying it with an aperient pill. I can safely say that I have seen no internal remedy influence the discharging stage of eczema, or eczema siccum of the hands, so rapidly and effectually as these. When properly aided by baths, aperients, exercise, and suitable food, nearly every case of eczema in the stage and form I have mentioned will be cured or relieved by a persistent use of them, as I have had the pleasure of demonstrating to several gentlemen at St. John's Hospital. There are, however, some precautions with respect to the mode of taking them which are of vital importance.

In the first place it is essential that the tincture should be prepared, not only according to the "London Pharmacopœia," but with such care as to ensure that no great amount of free acid is present, seeing that this frequently preponderates to such an extent that the tincture cannot be given in the proper doses. Indeed, the fluid part of a good deal of the trash sold under the name of tincture is composed almost wholly of hydrochloric acid; it is sold to patients at a price for which a surgeon could not buy it from a respectable chemist. When properly made a drachm or more may be given at a time, whereas half a drachm of the coarse acid tincture will set the teeth on edge and make the patient feel sick. I have several times known a patient who was taking the pure tincture with benefit turn quite ill after a dose of this stuff; severe vomiting has followed in several instances, and in one case where I was consulted, the patient was so sick, and purged so violently from taking two drachms of the common tincture in divided doses, that his friends thought he had got English cholera. This kind of thing has now happened so often that I always beg of patients, if they run short of the genuine tincture, rather to do without it for a day or two than get it from any source they are not certain about. The tincture of the perchloride of the "British Pharmacopœia" is a much inferior preparation. With whatever care it be made the iron speedily precipitates, and as druggists do not like to send out a thick-looking tincture, they pour off the clear fluid and make use of that only, rejecting

the greatest part of the iron. But it is only too often not prepared with care. In making the solution of the perchloride, instead of evaporating this in a water bath, the ingredients are simply mixed, and the spirit added subsequently; an addition which is the signal for approaching precipitation of the metal. Indeed, I would in every case recommend the acid solution in preference, giving the spirit separately in a more palatable form.

The tincture must be given in pretty large doses, and for some time. It is of no use prescribing fifteen or twenty drops twice a day for two or three weeks; as well not give it at all. The patient, if an adult, should begin with half a drachm at least, and increase this as rapidly as ever he can to a full drachm, beyond which it is rarely requisite to go. The dose should be measured out in a minim glass; for as a drachm is equivalent to quite a hundred and fifty drops, the surgeon who prescribes a certain number of drops is evidently not giving the quantity he wishes to do.

Now and then, if the patient grow sick of the medicine, or suffer from dyspepsia, loss of appetite, headache, &c., the steel may be given up for a day or two till these symptoms pass off; but so soon as they have vanished it should be resumed. The constipation which generally accompanies its use may be easily remedied by the use of a mild pill, which should, however, always contain aloes.\* This symptom frequently passes off when the steel has been taken for a little time, and especially when the larger doses have been reached. I have so repeatedly noticed this, that I have been obliged to conclude, that a small dose of steel constipates as readily as a large one, and that the constipating action begins almost as soon as the patient begins with the medicine; whereas the purging induced by the acid is in exact proportion to the quantity taken, and comes on more slowly. The dyspepsia, the most frequent form of which is marked chiefly by coldness at the stomach, nausea, griping, and flatulence, is generally soon got over by leaving off the steel and giving some mild aromatic and ant-acid, such as carbonate of soda along with compound tincture of cardamoms, or aromatic confection, or the aromatic spirit of ammonia in some bitter infusion † Should the appetite flag very much, the patient may give up the steel for a week or two, and take the nitric or nitro-muriatic acid, as previously suggested, for a few days. In some extremely rare instances it may happen that the patient cannot take either of those preparations of steel, in which case they should be abandoned in favour of the ethereal tincture or Griffith's mixture, but neither of these is equal to the former. Indeed, in my hands the ethereal tincture proved useless or nearly so. It is altogether a medicine not to be trusted to, and the dose usually given (five to thirty minims), is far too small. The first-named dose would be about the right strength for quieting the nerves of a hysterical baby. I have never seen anything exert so much control over eczema as the acid solution and the tincture of the sesquichloride. At one time I believed that, provided steel were given in a soluble form which would sit lightly on the stomach, it did not much matter what preparation was used; and I believe that in the discharging stage almost any preparation of steel, perseveringly given, will effect a certain amount of good; but I consider my observations warrant me in drawing the conclusion that those I have recommended are among the most potent we possess. I have frequently treated two similar cases of eczema—one with the acid solution and one with some other preparation. I have also in such cases given one patient the acid solution, and one the nitro-

muriatic acid or a saline. I have suspended the acid solution and given something else; and sometimes when a patient has returned with a fresh outbreak, I have tried this time to do without the solution, but always with the same result. Even in the dry furfuraceous state of the skin, with fine, thin, adherent crusts, the solution of iron, properly seconded by aperients, often proves useful. I have seen lichen, too, which had improved under salines, develop into eczema under the influence of mercury, and again improve directly the acid solution was given.

These preparations of steel, given in this way, and aided by an aperient, will cure a great many cases without anything further being required; but in some instances the dry stage itself of eczema demands a particular course of treatment; and in others not only does improvement cease without any manifest cause, while the patient is taking the steel with every possible precaution, but an unmistakable relapse ensues. In the latter case the best plan seems to be to give up the steel altogether for a week or two, to purge the bowels well, and then resume the steel in increased doses, by which means the surgeon can generally succeed in bringing the disorder to the third or dry stage. The health almost always improves visibly under the use of these remedies, the skin grows clearer, and the muscles become firmer, while the face frequently loses to a great extent the careworn look it had acquired from long ill-health.

4. *A Course of Arsenic, aided occasionally by Cod-liver Oil and an alterative preparation of Mercury.*—Arsenic properly given, that is to say in just such doses as the patient can bear without being made unwell by them, will cure a great many, perhaps most cases in the dry stage, in which alone it is useful. In other phases of eczema it has always appeared to me inert or injurious; but when the skin is simply red and tender, with a quick reproduction of unhealthy cuticle or scales, it is often of great benefit.\* Given alone in eczema, before steel has been tried, and in the weeping stage, it makes the patient sick, languid, and weak, destroys the appetite, and purges the bowels. Should, however, the surgeon only see the patient first of all at this stage, and ascertain that he has not taken steel, then I would suggest that the patient should either go through a short course of steel, or that this medicine should be combined with the arsenic; for though the statement may excite scepticism, I feel justified in saying that many patients bear arsenic decidedly better after a course of steel. I have repeatedly observed that, where patients could not tolerate even five minim doses of liquor arsenicalis without so much irritation of the stomach, nausea, and purging, sometimes even followed by a very disagreeable result—peeling of the skin of the hands and feet—that the medicine had to be given up even at the risk of seeing the worst symptoms return; these doses, after a course of steel, excited no discomfort except in the conjunctiva and not much even there. I believe, however, that this toleration of arsenic is quite artificial; after a respite of a few months I have seen the same quantity of it produce the same disagreeable effects.†

One of the fashions or crazes of the day is that of giving arsenic in every disease of the skin. The extent to which this has grown of late years is almost incredible, and is perhaps known only to the druggists who supply the material. A few years ago arsenic was scarcely employed at

\* In the *Dublin Quarterly Journal of Medical Science* for May, 1870, there is a case by Drs. Benson and Smith, in which the patient's disability steadily increased under quinine, iron, mineral acids, &c.; where-as the use of arsenic was followed by immediate and lasting improvement.

† As a formula for giving arsenic in pills is sometimes useful I sub-join one:—

When it is considered necessary to add steel, ʒss of the magnetic oxide of iron may be substituted, with a little mucilage, for the extract.

all internally, and was given with great caution, or even altogether withheld in complaints like lepra and lupus which could scarcely be cured without it. Now-a-days it is constantly prescribed in every case that proves the least refractory, and very often before any other medicine is tried. Indeed, medical men often adduce as evidence of the refractory nature of a particular case—*e.g.*, of eczema itself—that the patient has taken a quantity of arsenic without its doing any good. Why, I don't know, as certainly it never was recommended in every disease of the skin, and especially in the weeping stage of eczema, by those who are supposed to lead opinion. But there are some affections of the skin which never require arsenic, and many which only tolerate it at a certain stage. Among the latter is eczema. So long as ever there is discharge of serum, arsenic never does any good, and often does a great deal of harm by inducing sickness, purging, headache, and general irritability. It is only of use when the dry stage has set in, and is not always called for then. Attention has often been directed to the injurious nature of such treatment as that of acute eczema with preparations of arsenic, but so far without result; indeed, the practice seems largely on the increase.

(To be continued.)

## Foreign Medical Literature.

### ON DRUNKENNESS AND ALCOHOLISM

FROM THE

#### POINT OF VIEW OF LEGAL REPRESSION:

A SPEECH BEFORE THE NATIONAL ASSEMBLY

IN PARIS IN AUGUST.

BY DR. THEOPHILE ROUSSEL,  
Deputy to the French National Assembly.

DRUNKENNESS does not appear in former times under phases so sad and degrading as those which it assumes in our days. We perceive nowhere this series of evils which it now entails on the family and on the human species. The literature and the fine arts often give to it an aspect coloured and life-like; and old Silenus with his flabby and obese body seems to be its most abject type.

Drunkenness has not been less opposed in the commencement of civilisation by severe and often excessive penalties. This extreme rigour is noticed in spite of necessary temporising in the edicts which have been law up to the last century; and this is one of the causes of their inefficiency and of that rapid disuetude, a phase common to all laws which are excessive in their severity.

Two other circumstances have not been less instrumental in weakening the action of the law. On the one side, drunkenness was, above all, the vice of the rich and idle; on the other side, it was then a much less serious evil than it is now, both for the individual and society.

Up to the time when distilled drinks replaced fermented liquors, drunkenness amongst all peoples with which history is acquainted has predominated in those classes which possessed the means of indulgence, and were not deterred from it either by moral education or culture of the mind, or by their mode of life. The mass of the people, on the contrary, were kept by the hard necessities of their life in a state of enforced temperance.

Thus, drunkenness figures in Greece, in the Roman Empire, and in the middle ages, among the Christians as a diversion of the courts, and as one of the necessary relaxations from the fatigues of the military profession. The Bulls of the Popes and the canons of several Councils, prove its encroachments among the clergy and in monastic life. Petrarch and his contemporaries have proved it to be habitual among the popes at Avignon, and a physician who practised in that city in the time of Guy de Chauillac,

Raymond Chalin de Vinario, attributes to it the enormous mortality which attacked the Papal Court during the great pestilence of the fourteenth century. Although Cesar has spoken of the temperance of the Suabians, Tacitus, a little later, has remarked the propensity of the Germans to drunkenness as a trait remarkable in the midst of the rustic simplicity of their tastes relative to alimentation. This habit which has marked all the countries of the Anglo-Saxon race in its vast expansion over the world is vouched for by many documents in which drunkenness appears as a vice of the princes and lords of the German Empire. In the sixteenth century it was the subject of numerous edicts, at which the nobility were in the habit of scoffing, glass in hand. The Diets gave rise, from this fact, to such scandals that it was said these assemblies were so embarrassed and obscured by wine that they could only speak reasonably in the morning. J. P. Frank, to whom I owe this fact, added that they called the laws which the Diets made "Morgensprache" (Morning speeches), because all that was said after midday was held to be of no value, because of the wine and beer. The habit of drunkenness amongst the German nobility is again attested by the creation of two orders of chivalry founded like our modern temperance societies upon the vow of abstinence from strong liquors.

But the drunkenness of wine, beer, and other fermented liquors, familiar to the ancients, had not the formidable character that has been given to it by the propagation amongst the masses of working men brought together and salaried by modern industry of a new agent produced artificially from another industry unknown to the ancients—alcohol.

The beverages with which men formerly got drunk contained only a moderate proportion of alcohol, this spirit which distillation separates from the other elements of wine, and which it more recently has extracted at a low price in profusion from all elements containing sugary matter. These beverages excited at first the senses, next affected reason and the regularity of motion, but did not produce, in general, very great disturbances in the organism; this is why drunkenness, even when habitual, caused formerly, less rapidly and completely than now, the loss of the moral faculties and judgment, and those grave alterations of the organism which constitute the modern pathology of alcoholism, for which the language of nosology has created since 1813 a particular nomenclature.

This less serious result of drunkenness even when repeated explains some proverbs in vogue amongst our fathers in favour of this vice and the singular precept of hygiene—to get drunk once every month—which obtained at two different times the honour of a solemn refutation before the Faculty of Paris in the seventeenth century. It explains at the same time as this indulgence of opinion which paralysed the laws, the indifference of physicians on a subject on which for the last half century they have not ceased to give the alarm to the public powers.

## THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XXVI.

AGRICULTURAL VALUE OF SEWAGE.

THE history of sewage irrigation affords a striking example of the readiness with which a plausible theory may be accepted, and promulgated by men of enthusiastic temperament, whose minds are given to speculation without the corrective influence of proper experience. Seeing that in the warm climate of Egypt, China, Persia, India, Piedmont, Lombardy, and elsewhere, water has from time im-

memorial been successfully used for irrigation purposes, and has given fertility to certain arid and otherwise almost barren districts, it has been at once concluded that sewage, which is water *plus* a small quantity of manure, must necessarily be suitable for every kind of soil, and every variety of crop, in every description of climate. This is the theory which is earnestly recommended to the notice of the British farmer, whose so-called "pig-head reverence for the practice of his forefather, and ignorant belief in his own experience" make him extremely cautious in accepting it; for he rightly thinks that the condition of the soil in the cold and humid weather of this country is very different from what it is in the warm and dry atmosphere of the south: in fact, one of the greatest difficulties he has to contend with is a superabundance of water in the land during the greater part of the year; and with the view of remedying this he has adopted the system of thorough and effective drainage. It is not likely, therefore, that he will readily accept a theory which requires him to ignore his experience and nullify his practice by converting his farm into a swampy morass. A few enthusiasts, however, have accepted the hypothesis; and in putting it into practice have occasionally found that in certain seasons, especially with light and porous soils, the results have been highly successful; but the success has never been enduring, for it has depended upon conditions of season as regards drought which is altogether exceptional. When this has been otherwise, as in the experiments at Alwicks, the results have been disastrous. Even in ordinary times there is an average of 150 wet days in the year, when sewage cannot be profitably applied to the land. On the other hand, however, it sometimes happens, as in Lombardy and Piedmont, that the seasons are so dry that the application of even water to the land is extremely beneficial. On such occasions the farmer would gladly take sewage, as he would water, for the parched and hungry crops. But this is not a common occurrence, and rarely lasts for more than a month or so. To be compelled, therefore, to take sewage at all times throughout the year is a condition of things which the farmer very properly declines, for under such circumstances, according to Mr. Lawes, it is inapplicable to every description of crop; whereas if a person can apply it to-day, and not to-morrow, just as he pleases, he may use it with every description of crop. Professor Way is of the same opinion, for he says, "if the farmer is bound to take large quantities of sewage at all times, he will decline to take it at all, because he cannot take it in times of rain, and it must be put upon land properly prepared for it and laid out as a sewage farm." Evidence to the like effect has been given by Mr. Congreve, who managed one of the sewage farms at Rugby, and who found from experience that the taking of sewage at all times throughout the year was the great difficulty in the matter. "If I had a farm," he says, "in the neighbourhood of London, I would take sewage if I were at liberty to take it when it suited my purpose; and should apply it over a very limited area at a certain time of the year; but if I were compelled to take it at all times, I should refuse it altogether." Mr. Mechi is evidently of the same mind, for he says he would rather not be regulated as to the time of applying it, but would use it when he wanted it. This, indeed, is exactly the way in which it is dealt with at Worthing, Birmingham, and Edinburgh, where the farmers know what they are about; and this was so strongly impressed on the Parliamentary Committee of 1862 and 1863,

that they stated in their report of the evidence before them, "that it is desirable that those using sewage should have a full control over it, so that they may apply it when and in what quantities they may require." In proof of this the Committee have quoted the evidence of Mr. Lawes, Professor Way, Mr. Tregelles, Mr. Samuel Christy Miller, Mr. McCann, and Mr. Miles; in fact almost every witness before the Committee spoke of the difficulty of managing a sewage farm, so as to get rid of the sewage at all times; and, as might be expected from the perplexities of the subject, there is the widest difference of opinion respecting the time when sewage ought to be put upon the land, so as to be most profitably and safely utilized. Mr. Mechi applies it to meadow land from the beginning of May to nearly the end of June; and on feeding-pastures he uses it at all times during active vegetable growth. The Earl of Essex puts two dressings, each of 225 tons to an acre upon his meadow land for hay, from October to January or longer; and he uses it in the summer time directly after cutting a crop of Italian rye-grass. Mr. Tregelles employs it for pasture land during the winter, and root crops in summer, using it upon swedes when they are as big as marbles, and mangolds all the while they are growing. But as rye-grass is the only plant that will stand a thorough and nearly constant dressing of sewage, it is *par excellence*, the crop which is selected wherever there is much sewage to be disposed of; and, although it is often killed by excess of sewage, especially in frosty weather, yet in summer time it is often treated to a liberal allowance of it, almost to the time of cutting.

A like difference of opinion exists as to the way in which the sewage should be distributed upon the land. Mr. Smith of Deanston, who was the first to dream of the profitable utilisation of sewage by irrigation, proposed that it should be applied by means of hose and jet, in the fire brigade fashion, under a pressure of a column of liquid 150 feet high. This, he thought, would force the sewage through the elaborate system of underground pipes, which were to be laid down in every sewage farm, and drive it to the place where it was wanted. Mr. Edwin Chadwick adopted this idea, and used all the influence of the old Board of Health to get it put into practice throughout the United Kingdom. Thousands of blue books, with detailed instructions for arranging the pipes and pumps of sewage farms, were circulated by the Board. Popular lectures were given, speeches were made, and sensational articles written, to show the value of sewage as liquid manure, and how it ought to be pumped on the land. It was, in fact, one of the instructions of the Board that every system of sewers should be brought to one outfall, with the view of applying the sewage to agricultural purposes. Mr. Mechi, Mr. Telfer, and Mr. Kennedy were among the first to accept the tempting theory and to put it into practice. Soon after, it was adopted by Mr. Walker of Rugby, Mr. Neilson and Mr. Littledale of Liverpool, and Mr. Chamberlaine of Norwich, nearly all of whom have had cause to repent it. The history of Mr. Walker's failure is worth recording, for it is typical of all the rest. In 1854, when the sewage of Rugby had become so unbearably offensive that Mr. Walker was contemplating legal proceedings to abate it, he unfortunately met with Mr. Chadwick's glowing account of the agricultural value of sewage; and fancying there was a fortune in the nuisance if properly dealt with, he entered into an agreement with the Local Board of Health, to take all the sewage of Rugby for twenty years, if they

would deliver it upon his land, and make all the necessary arrangements for distributing it thereon by hose and jet. The Board, therefore, erected a steam-engine for pumping the sewage, tanks for collecting it, and a proper system of pipes for distributing it—gladly paying the heavy expenses thereof to be rid of a troublesome nuisance; and Mr. Walker no doubt laughed in his sleeve at the apparently hopeful bargain he had made; but, alas for human foresight, the results were so unprofitable that the bargain was at length repudiated, and the pipes are no more. This, however, is the system which is still advocated by Mr. Mechi, Mr. Ellis, Baron Liebig, the Earl of Essex, Mr. Miles of Bristol, and the Chairmen of the Parliamentary Committees of 1862 and 1863, all of whom say that small dressings of sewage, by means of hose and jet, are more profitable than larger dressings by open carriers. But this is not the opinion of Mr. Lawes, Professor Way, Dr. Voelcker, Mr. Christy Miller, the late Sir Joseph Paxton, Mr. Blackburn, and Mr. Rawlinson, all of whom recommend the distribution of sewage by open carriers—permanent or moveable. In most cases the carriers are permanent, but at Mr. Hope's farm at Romford, and Mr. McDougall's at Carlisle, they are moveable. In every case, however, the land must be properly prepared for it, so that the sewage shall be evenly distributed, and the subsoil water freely removed.

As to the quality of soil which is best suited for sewage irrigation there is likewise much difference of opinion. Most agricultural chemists of large practical experience advocate the use of a porous sandy soil. Dr. Voelcker, for example, says that all liquid manures produce the most beneficial and striking effects when they are applied to light, deep, and sandy soils, resting upon a porous subsoil—soils containing from ninety to ninety-six per cent. of sand and but little alumina, so that the sewage may go through it and not over it. Professor Way also states that he would select a pure sandy soil in preference to anything approaching clay, because sand will become richer in clay every year that sewage is applied to it—apart from the fact that clay can always be added to sand if necessary, whereas no clay soil can be made open enough to receive sewage—in fact, “a dry absolute clay is,” he says, “the last soil I should wish to use sewage upon, because although it has the power of extracting manurial qualities of sewage, the sewage cannot get into it. Even if the clay were ever so well-drained, the liquid would run over it.” According to Mr. Lawes it is best applied to the most porous, sandy, and sterile soils, like that of Bagshot Heath, and the same opinion was entertained by the late Sir Joseph Paxton.

On the other hand, some chemists are of opinion that the soil should contain a notable proportion of clay, because clay has the largest power of absorbing ammonia, phosphoric acid, and potash—the most important constituents of sewage. Baron Liebig opposed the scheme for distributing the sewage of London upon the Maplin sands, because they do not contain sufficient clay, and he attributed the success of the Craigintinny meadows at Edinburgh, to the circumstance of their containing much alumina. He thought, indeed, that the Maplin sands would require at least two million tons of clay to give them fertility to the depth of an inch.

Mr. Bailey Denton, who has recently acquired popularity in connection with this subject, is of the same opinion, and argues that a soil with a considerable portion

of clay is better than a very porous soil, because it delays the percolation of sewage, and retains the manurial elements. But then the land must be thoroughly drained, for that is Mr. Bailey Denton's speciality, and he blames the Rivers Pollution Commissioners for not making it a *sine quâ non* that no irrigation should be practised without deep subsoil drainage.

The value of clay as a constituent of ordinary soil is admitted on all hands, for it not only absorbs and fixes the chief elements of manure, but it also elaborates them, and fits them for the use of the growing plant. This power was first investigated by Bronaor in 1836, and afterwards, in 1845, by Huxtable and H. S. Thompson. Later still, in 1850, 1852, and 1855, it was still further examined by Way, who thought that the absorbent power of a soil was dependent on the chemical action of certain silicates of lime and alumina, which fixed the alkaline bases, and allowed the acid constituents (phosphoric acid excepted) to pass in combination with lime. Liebig's views at first were entirely opposed to these opinions respecting the absorptive power of soils; but, in 1858, he ascertained from experiment that every plant-bearing soil absorbs the fertilising elements of manure—clay doing it best, and pure sand worst—whilst turf and peaty matters had an intermediate action. He found that a common clay soil in the neighbourhood of Munich would absorb (per acre, four inches deep) 2,076 lbs. of ammonia, 1,910 lbs. of potash, and 888 lbs. of phosphoric acid; and that the action was not merely of a physical nature, for it seemed to prepare and elaborate the materials for the use of the plant—acting, in this respect, like the stomach of an animal. Voelcker also found in his experiments that all soils absorb ammonia from its solutions, clay doing it best, and organic matter worst, the difference in other soils being but slight. He ascertained, however, that the whole of the ammonia was never, in any case, entirely removed, however strong or weak the solution of it was, and that water would subsequently wash it out again, to some extent, though not completely. Potash salts were most freely absorbed by clay, and hardly at all by sand; and with respect to the phosphoric acid of soluble superphosphate, it is absorbed and rendered insoluble by all arable soils—chalky and marly soils acting more powerfully than clay or sand—the change being not immediate, but the work of time, and requiring a large proportion of soil.

The agents which are chiefly concerned in these remarkable effects are alumina and hydrated oxide of iron, with lime and other bases. Warrington, indeed, has proved that, although all the constituents of a soil, except quartz, have the power of absorbing manurial elements, yet alumina and hydrated oxide of iron possess it to the largest extent, the order of absorption being as follows:—for acids, phosphoric, carbonic sulphuric, muriatic, and nitric; and for bases, ammonia, potash, magnesia, lime, and soda—the form in which the base is best appropriated being the hydrate, phosphate, or carbonate; the sulphate, nitrate, and chloride being but slightly absorbed. The extent to which the solution is diluted is also a matter of considerable importance; for, although Liebig and some others are of opinion that the soil will appropriate the manurial elements of a solution, no matter how dilute it is, yet Voelcker has proved beyond all question that weak solutions, like sewage, will actually remove those elements from a soil, and that unless a plant is growing,

and is therefore able to appropriate the elements of sewage at the time it is applied, there is no power in the soil to arrest the elements, and to store them up for future use, when they are continuously applied in such a weak form. The action of the soil, therefore, under such circumstances, is merely to strain the liquid, and to effect the oxydation of its nitrogenous compounds, which pass away as nitrates and are entirely lost. This is easily proved by an analysis of effluent sewage water when vegetation is inactive, and the plant is unable to appropriate nitrogenous matters; for at such times, the sum total of all the soluble nitrogen in the sewage is found in the effluent water in the form of useless nitrates. It is very doubtful, indeed, whether at any time the nitrogenous matters of sewage are entirely utilised by the plant, even in its most vigorous state of growth, and whether the plausible theories which are so rife concerning the value of ammonia, &c., in sewage, are not altogether erroneous. A glance at the table which is given at page 46 of the Third Report of the Commissioners appointed to inquire into the best mode of distributing the sewage of towns (1865), will show that the amount of soluble organic matters of sewage, as estimated by the process of incineration which was then in use, is not very different from that in the effluent water.

| <i>The two fields—</i>                      |                         | <i>The two fields—</i>                                    |                         |
| Raw sewage . . .                            | 7.71                    | Raw sewage . . .  | 8.32                    |
| Effluent water . .                          | 7.56                    | Effluent water . .  | 7.73                    |

These were the results of sixty-two analyses; and in commenting on them the Commissioners say that, "of the matter in solution, a gallon of drainage water contained sometimes more and sometimes less, but on the average much about the same amount, both of organic and inorganic as a gallon of the sewage." In criticising this remark, the Commissioners appointed in 1868 to inquire into the best means of preventing the pollution of rivers (First Report, 1870, p. 71) say,—“There can be no doubt that these results, and the statement founded upon them, so far as it relates to organic matter, are erroneous, and that the cause of the fallacy lay chiefly in the absence of nitrates in the raw sewage, and their presence in large quantities in the effluent water.” But in many cases, the oxydation is far from being complete, especially when the land is overtaxed. Professor Way says that if sewage be put upon a soil in larger volume than about 1,500 tons per acre per annum, even with rich growing Italian rye-grass, the sub-soil water is foul. The same fact was observed by Mr. Westwood, of the Annerley School Farm, who found no difference in the results, as regards the crops of rye grass, whether he used 1,500 tons per acre by hose and jet, or from 8,000 to 9,000 tons per acre by open carriers ;

but in the latter case the effluent water was almost as foul and as high coloured as the original sewage. In the experiments at Rugby, Mr. Lawes noticed that, although there was an additional crop of grass with an increased flow of sewage, yet it was by no means in proportion to the quantity used; for, while with 3,000 tons of sewage an acre he got 22 tons of grass, yet with 6,000 tons an acre he got no more than about 28 tons of grass, and with 9,000 tons an acre only 32 tons of grass. It is evident, therefore, that neither the plant nor the soil is capable of appropriating all the manurial elements of sewage, and that, therefore, they must pass away in a more or less oxydised and useless form.

This brings us to a question of great practical importance, namely, how much sewage can be profitably and safely applied to a given area of land. On this head, as on every other, there is the greatest difference of opinion, although it results generally in the fact that the sanitary and commercial aspects of the question are widely opposed, it being impossible to realise agricultural success, with a perfect deodorisation of sewage; for, in one case a large proportion of sewage is required, and in the other a small.

ABSTRACTS OF INTRODUCTORY LECTURES

DELIVERED AT THE

OPENING OF THE MEDICAL SESSION,  
1871-72.

UNIVERSITY COLLEGE.

AFTER remarking that “words of advice and counsel had been so often uttered to the new comers,” as to make it almost useless again to take up such a well-worn theme, Dr. Charlton Bastian entered upon the topic of *The Nature and Origin of Epidemic and Specific Contagious Diseases*. He now took up this subject because, being “deeply impressed with the difficulties surrounding these great problems, and with the enormous importance of strengthening the foundations of our knowledge in respect to them,” he had been induced more than two years ago to investigate some questions which lay at the root of the whole subject. It seemed to him that “no real advance could take place in our knowledge of these diseases until certain other great problems had been settled. What is the real cause of fermentation and putrefaction? Can the organisms which are associated with many of these processes arise *de novo*? These were questions the solution of which seemed of the utmost importance to the science of medicine, as well as to the cause of science generally.”

After reviewing the mode of origin and distribution of such morbid products as cancer and tubercle, Dr. Bastian proceeded to show that the knowledge which we have acquired concerning them is capable of throwing “much light upon the history of general so-called ‘specific’ affections, and their mode of distribution through communities, or from individual to individual.” Can cancer or tubercle arise in the individual without any pre-existing hereditary taint? Can the states of blood peculiar to the several specific affections arise *de novo*, or independently of contagion? These are questions whose import and significance are really similar.”

The Lecturer then traced the origin of “The Germ Theory of Disease,” showing, on the one hand, how it was principally “based on doctrines relating to the cause of fermentation, and on the other, how much all existing evidence was opposed to its truth, except in reference to certain general parasitic diseases, in which minute organisms were known to pervade all the tissues of the body. These parasitic diseases were, however, notably different from the specific fevers, and very many other contagious diseases to which the ‘germ-theory’ had been supposed to apply.” The theories of Liebig were then explained in reference to the zymotic diseases, and the

action of their poisons was contrasted with those of other better known organic poisons. An attempt was made to show how the gulf might be bridged which at present appears to separate the effects of snake poison from those of hydrophobia and other contagious affections, in which the virus is reproduced within the body.

After having alluded to the evidence which we possess concerning the "spontaneous" origin of very many of these maladies, the Lecturer said:—

"Now the remaining members of the group of specific infective diseases are varicella, whooping-cough, measles, scarlet fever, and small-pox. The knowledge which we possess concerning the mode of origin of these otherwise than by infection is almost *nil*. They differ amongst themselves, it is true, as regards their degree of infectiousness: but, as others have suggested, they are probably more strictly dependent upon individual states than upon external conditions, and, consequently, are more baffling to those who attempt to fathom their causes. Measles, scarlet fever, and small-pox, are undoubtedly amongst the most contagious of diseases, and, therefore, are the chances always strongly in favour of their contagious origin in any given case. But should this satisfy us? Should we be content to say that even measles, scarlet fever, and small-pox are propagable only by means of contagion, and cannot arise *de novo*? Are they not strictly comparable with many other general infectious diseases which undoubtedly arise 'spontaneously'? Do we not see amongst those which may so arise that the degree of contagiousness is altogether variable? Does not this seem gradually to increase in each affection, as the off-cast particles have tendencies to undergo molecular change which are more and more capable of initiating chemical actions of a spreading character in the blood or mucous surfaces of ordinary individuals? And does not the diminishing contagiousness of different diseases seem to be due to the fact that off-cast particles are less and less capable of acting upon the healthy fluids and mucous surfaces of the body, but require that these should be altered, now by one set of agencies affecting the general health, and now by another, before such particles can initiate those changes which lead to the evolution of one or other of the specific poisons within the body? Whooping-cough, measles, scarlet fever, and small-pox, would in this case be merely the last terms of a series, differing from the other members simply in degree, but not in kind—and therefore as capable of being generated *de novo* as either of the others, although much more capable than they are of being disseminated by means of contagion.

"If we reject this notion, what remains for us? The germ-theory is quite untenable—the analogy which has been thought to exist between the causes and nature of certain diseases and the specific and unalterable characters of living organisms is erroneous in both its aspects. And even if the diseases are *now* only propagable by contagion, just as the higher living things are propagable by reproduction, they must nevertheless have originated once; and if once, why not now? Or, declining to admit even so much, shall we refuse to bear our own burdens? Shall we shift the difficulty, and suppose that the poisons of syphilis, measles, scarlet fever, small-pox, and other diseases, have been evolved amidst the unknown conditions obtaining upon the surface of an unknown world, whose disruption has scattered them broadcast, and conveyed them to us, with other never-dying germs, upon the verdant surface of a 'moss-grown fragment?' With such alternatives, surely our choice cannot be doubtful."

In conclusion, Dr. Bastian said:—

Let us not be blinded, however, by any narrow or exclusive theories which would teach us that epidemic and infective diseases cannot arise *de novo*. Let us, instructed by a broader survey of the facts, assign no such limits to natural possibilities, and not lightly accept theories which lead to supineness, when we ought to be stimulated to exertion. Whilst accepting to the full all doctrines which inculcate the necessity of diminishing the chances of contagion by every available means, let us, full of hope, diligently seek also for the causes which engender even the most contagious of diseases. Prevention of disease is the grand end and aim of medicine; if, then, we have learned from the sad lessons of experience that scarlet fever and small-pox are virulently contagious diseases; if, even in ninety-nine cases out of a hundred, or even in a still larger ratio, both of these diseases are acquired by contagion, then is it all the more important that we should strive to ascertain what are the invariable and immediately antecedent sets of conditions, or states of system which suffice

actually to engender these maladies. In such cases knowledge and power are most frequently convertible terms. Next to typhus fever, the most fatal of the infective diseases which occur in this country are scarlet fever, small-pox, measles, and whooping-cough. The ravages of typhus in our crowded cities and in our jails have been enormously curtailed, not so much because of its diminished spread by contagion, but rather because we have learned what are the causes which engender it, and are, therefore, better able to prevent its occurrence. Let us strive, then, to acquire a similar knowledge concerning scarlet fever, small-pox, measles, whooping-cough, and other contagious diseases, and so endeavour, in the most efficient manner possible, to check the ravages of these *morbi populares*.

Time will not permit me even to allude to the many other interesting and important problems which still remain to be solved in reference to these diseases. What I have said, however, will, I hope, suffice to inspire you with a sense of the great difficulty of the problems which you will subsequently have to face; and, therefore, to make you feel the urgent need for diligent, patient, and honest work all through your career—without which you will not be able conscientiously to accept the high responsibilities that will subsequently devolve upon you as practitioners of medicine, and without which no real advance in knowledge can ever be made.

#### ST. THOMAS'S HOSPITAL.

THE Lecturer first referred to the removal of the hospital from its former site to its present position, contrasting the two, and paying a well-merited compliment to the treasurer, Sir Francis Hicks, for the untiring energy he has devoted to the completion of this great work, and likewise to the governors for their enlightened appreciation of the importance of making suitable arrangements for a large medical school. He then gave a brief history of the origin, foundation, and development of the hospital, from the earliest notice of its existence to the present time; and subsequently referred to many circumstances of interest recorded in the chronicles of the establishment. The names of the various medical officers who have been attached to the hospital, and whose reputation has been handed down to us, were next noticed; and the Lecturer especially dwelt on those of Cheselden and Mead, whose busts have been presented to their alma mater by the "Old Students."

The sudden death of his late colleague, Mr. Solly, was alluded to by the Lecturer, who remarked that they had been associated at the hospital through life, and that he could not recall a single hour during which the harmony of their intercourse had been interrupted.

Having contrasted the existing with the past system of hospital education, the Lecturer dwelt at some length on the relative duties and responsibilities of teachers and pupils; and alluded to the deep interest he felt in the proposed arrangement for amalgamation between the incorporated bodies and the universities, with a view to having one common portal by which all candidates may obtain a qualification to practise their profession.

The lecture was concluded by a personal appeal to the students, and the expression of a confident anticipation that the future career of the new hospital and school would prove worthy of its past history and of its existing habitation.

#### MANCHESTER ROYAL SCHOOL OF MEDICINE.

THE Opening Lecture at this institution, by Mr. R. T. Hunt, Demonstrator on Diseases of the Eye, was chiefly occupied in explaining the lecturer's views upon education. Speaking of anatomy and physiology he said—I fear that the attention of students of the present day is too much devoted to minute or microscopic anatomy, before having thoroughly acquired a knowledge of elementary anatomy. By elementary anatomy I mean that knowledge of all the structures of the body which can be obtained by teaching, by observation, and more particularly by dissection. I do not at all wish to discountenance minute anatomy, but during the course of medical study it is much more material thoroughly to acquire the elementary knowledge before the student attempts microscopic examinations, except under the direction of his teacher. The results of these he will have described to him in the lectures, and he can rely upon these until the advance of medica

science clears up many difficulties connected with minute anatomy. Physiology, which is founded upon anatomy—the knowledge of structure necessarily leading to the use for which such structures are intended—will require your strict attention, and you will in its study at once observe how much remains still unsatisfactory of this important department of medical science. Speaking of the many conflicting opinions and the different theories with regard to the functions of the various parts of the body, the lecturer reminded his hearers that as there are both true and false theories, it should be the business of every student, before accepting any theory, to see what there is to support it and what is said about it by those better able to judge of its correctness than ourselves. Sir Isaac Newton, for instance, no doubt greatly advanced the science of optics; indeed, almost all the rules of what may be called mathematical optics have only been the more distinctly proved correct by the lapse of time. But this does not apply to his theory of the real nature of light, which he supposed to be a material body that passed through transparent substances. According to the opinion of those best qualified to judge, the vibratory or undulatory theory is now proved to be the true one. If, therefore, a man of the transcendent talents of Sir Isaac Newton gave rise to a mistaken theory, scientific students should be very guarded in receiving any theory until it has been properly confirmed by experience. Among what I may presume to call modern fanciful theories is that ridiculous one of Darwin in regard to the origin of species, and of Huxley regarding vitality. Because these theories may be wrong—and are wrong in my humble opinion—that is no reason why we should rashly conclude that other theories proposed to us are not right; but we should at all events remember that the only theory which is truly useful is that which is not made for facts but is founded on them. Only some minds are fitted to theorise and generalise, but even the humblest among you can record, from your own experience, facts which may prove valuable as supplying missing links in some theoretic chain. While appreciating in your work the value of such mechanical assistances as the microscope, stethoscope, and ophthalmoscope, you must not place too much reliance upon these aids, to the neglect of your own natural means of acquiring information by observation in the science of anatomy, in *post-mortem* examinations, &c. The lecturer concluded by an appeal to the morals and good conduct of his hearers.

#### UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

The address was delivered by Dr. G. H. Philipson, and was devoted to the subject of education, with special reference to the student in medicine and surgery.

The effect of medical studies upon the intellect, first upon the power of attention and of memory, and afterwards upon the faculties of judgment, imagination, observation, and close reasoning, was fully set forth, the necessity of cultivating the power of observation being particularly enjoined. It being stated in studying medicine and in practising medicine, as every disease was a problem half known, half veiled in darkness, and as every patient presented not only what was known, but something peculiar and special, the practitioner of medicine had to make a constant reference to his memory and to his judgment, with the object of precisely interpreting its nature and its probable issue. It being to the discriminating exercise of observation that we are indebted for all that is known of the causes of diseases, as the recognition and interpretation of symptoms, and of the distinctive features of the different maladies.

The importance of constantly aiding the teaching of the lecture-room by the practice of the hospital, was then insisted upon. The two modes of study were to be conducted together. The knowledge contained in books was to be imprinted by the lesson of the ward, and the actual phenomena of disease was to give life and interest to the systematic description. Both were necessary, and the student would do justice to himself or to his art, if he showed energy in either mode of teaching.

The student was advised to repress all independent inquiry, to accept what was told him, without seeking to pass into the domains of original investigation, and to be satisfied with what might be termed the routine of science, until he was quite sure that he would avoid confounding probability with

ascertained fact, and he was able to subject all doubtful explanations to the test of a rigid logic. For as in his case speculation could not be corrected by direct experiment, and as imagination was best kept in bounds by a sufficient breadth of knowledge, he would arrive at conclusions which were utterly untenable, and form inferences which a deeper study would have shown him to be impossible.

After alluding to the obligations of the profession, and of the manner in which the practitioner of medicine was expected to conduct himself to his patients, to his professional brethren, and to the public, the lecturer said that the student had necessity for such attention that was about to enter upon a profession, which, if he would do justice to himself, would inevitably elevate him. But as the intellect has to lessen half of, and as the brightness of mere reason was eclipsed by the beauty of moral worth, the profession has to be entered upon with the object of elevating the moral faculties, as well as the perception and reasoning, whereby he would be enabled to act towards all men with justice, faith, and tenderness.

### QUALIFICATION FOR IRISH COUNTY INFIRMARIES.

WE understand that the recent election of Dr. Alton to the surgerency of the Tralee infirmary, of which we gave a full report some weeks since, is about to become the subject of an application to the Queen's Bench by Dr. Lalor, who was rejected by the casting vote of the chairman, and now contests the validity of the election—he does so on several grounds. He alleges that certain of the electors who voted were not qualified, and that the chairman was not entitled to a casting vote, having already voted as an individual governor. The principal ground of this application is that Dr. Alton does not possess the necessary qualification.

By the 36th George 3rd, Cap. 9, Section 3, it is provided that a candidate for surgerency to a county infirmary in Ireland must have obtained the Letters Testimonial of the Irish College of Surgeons. Dr. Lalor holds this qualification, but Dr. Alton does not. He is a Member of the London College, and Fellow of the Irish College, co-operated during the year of grace, 1844. The questions then at issue are, firstly, whether the 36th of George 3rd

ever was repealed, and secondly, whether Dr. Alton's fellowship is equivalent in privileges to the Letters Testimonial. As to this latter point some question may arise. The preamble of the supplemental charter under which the college exists, provides that the fellows of the college shall enjoy all the privileges of membership, but the 15th clause which arranges for the co-operation of medical practitioners to the fellowship during the year of grace has *not* the same proviso extending all the privileges of licentiates to fellows which is to be found in the clause, under which examination fellowships are conferred. We cannot say how far an Act of Parliament may be governed by a Royal Charter, but it appears to us that a fellow by examination would, under this latter clause, be entitled to discharge and fill all the offices of which Licentiates might have a monopoly.

### JOHN HUNTER.

SOME of our readers know, and as all ought to know we may announce thus prominently that it is proposed to place a memorial window of the founder of the greatest museum in existence, in the new parish church now nearly finished at Kensington.

The proposal is due to the initiative of Mr. Frank Buckland, who, in *Land and Water* last July, more than half accomplished his purpose, by the excellent sketch he issued of the great surgeon. It was in Kensington that the father of scientific surgery resided for thirty years, and the parish in which he carried on so many of his researches may appropriately commemorate him. It was Mr. Buckland, if we remember correctly, who discovered the remains of Hunter under the church of St. Martin's-in-the-Fields, and to his exertions we owe it that they were removed to their present resting place in the National Mausoleum.

We take from a recent sketch the following dates :—

- 1728. Born at Calderwood, N.B.
- 1747. Arrives in London.
- 1749. At Chelsea Hospital.
- 1751. At St. Bartholomew's.
- 1754. Entered St. George's Hospital.
- 1756. House Surgeon there.
- 1759. Staff Surgeon.
- 1763. Returned to England.
- 1764. Purchased Earl's Court House, Kensington.
- 1767. Elected F.R.S.
- 1768. Surgeon to St. George's Hospital.
- 1771. Marries Miss Home.
- 1775. First lectures on Surgery.
- 1776. Surgeon-Extraordinary to the King.
- 1786. Deputy Surgeon-General to the Army.
- 1788. Portrait taken by Sir Joshua Reynolds.
- 1793. Died in the room adjoining the Board Room of St. George's Hospital, on October 16th.
- 1859. John Hunter's remains discovered by Frank Buckland under the Church of St. Martin-in-the-Fields, and removed (by the Royal College of Surgeons of England) to their final resting place, on the North side of the Nave in Westminster Abbey, 28th March, 1859.

To this we beg to add the conclusion of Mr. Buckland's admirable sketch in *Land and Water* :—

Close to the mulberry-tree at one corner of the field is an artificial mound of earth very much the shape of an ancient burial tumulus such as we see on the Downs. The west side of this mound has a passage in it leading to three cellar-like vaults. This is even now called the

"Lion's Den," and there can be no doubt that John Hunter used to keep his lions and leopards in this place.

His sitting-room windows face this den, so that he could readily watch the animals from his easy-chair. This is doubtless the den from which his leopards escaped, the incident of which is thus recorded :—Two leopards broke from their confinement, and got into the yard with the dogs; a fierce encounter immediately commenced, the noise of which alarmed the neighbourhood, and quickly brought out Hunter to enquire its cause. He found one of the leopards engaged with the dogs, whilst the other was making his escape over the wall; and instantly, though quite unarmed, he ran up and laid hold of both the animals, which fortunately submitted to be led back to their den and secured. When the danger was over, however, he became so agitated at the recollection of it, that he fainted.

I closely examined these dens, but could find nothing but a very old decrepid wheel-barrow, which might have been John Hunter's from the look of it. In the largest den, however, I found a post and iron chain, such as is used for tying up cattle. The block of wood at the end of this chain is very old and worm-eaten, the chain also was very much worn. I think there can hardly be a doubt that this was the post to which John Hunter used to tie up the little bull which the Queen gave him, and which little bull nearly killed the great John; for the story goes that one day when wrestling with the bull the beast knocked him down, and would have gored him severely had not one of the servants driven the animal off with a stick.

On the top of the "Lion's den" there is a little rampart made of bricks and tiles, after the fashion of the top of a castellated tower. The legend is that John Hunter kept a gun here, which he used to fire off occasionally, a sort of private fortress, in fact; gun or no gun there is an excellent look-out from the top of the "Lion's den." In John Hunter's time Earl's-court was quite in the country, and from the "Lion's den" he would have had a good view of Westminster Abbey, little thinking he would ever be buried there. Near this place is a gateway, but neither I nor Merriman could make out whether this was a "dummy" gateway or intended for use; but depend upon it, John Hunter put it there for some purpose. His town house was situated about the middle of the eastern side of Leicester square, and extended through into Castle street, and here he established his museum. He used to drive a pair of bay-stone horses to and fro from Leicester square to Earl's-court. Foot writes :—"On being told of his death at St. George's Hospital, on the 16th of October, 1793, on the same day I recollect having seen his bay-stone horses returning through Piccadilly home without their master, and this circumstance introduced to my reflection the sympathy which Virgil has attributed to the war-horse of young Pallas in his funeral procession" :—

"Post Bellator Equus positus insignibus Æthon  
It lachrymans."

As I stood on the "Lion's den," I imagined this same carriage, with the high-stepping bay stallions, their coachman in tears, turning in for the last time to the very gateway after Mr. Foot had seen them in Piccadilly on the 15th October, seventy-eight years ago, and I pictured to myself the consternation and grief spread like wildfire through the establishment by the sad news of the master's sudden death. From that day the glories at Earl's-court then set. There can never be another John Hunter.

I have thus endeavoured to describe Earl's-court, the residence of our great and illustrious founder. During my visit there I almost imagined that I was in the presence of the great man himself, so little is the place changed. I wish, therefore, to call the attention of my brother medical men, and the scientific world in general, to the above facts. Mr. Merriman has kindly informed me that he will send to anybody who asks for it a picture of John Hunter's house and the "Lion's den" as they now stand, from drawings made by Mr. Arthur Roberts.

Earl's-court may disappear, but the memory of John Hunter will still be kept up in Kensington by the memorial window which it is proposed to erect in the new church. The larger the subscriptions, the more beautiful will be the memorial.

I cannot, I think, conclude this slight sketch of the great John Hunter better than by quoting the words of Sirach as recorded in the Book of Ecclesiasticus :—

“Let us now praise famous men and our fathers that begat us.”

“Leaders of the people by their counsels, and by their knowledge of learning meet for the people wise and eloquent in their instructions.”

“All these were honoured in their generations, and were the glory of their times.”

“Their bodies are buried in peace; but their name liveth for evermore.”

“The people will tell of their wisdom, and the congregation will show forth their praise.”

June 30, 1871.

FRANK BUCKLAND.

## Notes on Current Topics.

### One of the Hardships of the Lunatic Asylum System.

So much has been said on some points of our Lunacy Laws that it may be well to bear in mind the possibility of other hardships. We learn from the *Waterford News* the following facts :—

“A constable was called upon to take into custody a woman whose strange conduct led to the supposition that she was a lunatic, a belief afterwards proving correct. The woman, whose name was found to be Eliza Redmond, and a resident in Johnstown, was arrested, and was certified by Dr. Jackman as suffering under idiotcy; but of course it required two magistrates, as well as the doctor's information to admit her, and, two justices not being comeatable at the moment, the unfortunate woman was committed to jail on a warrant signed by Mr. Gould, R.M., who could not do otherwise, on the ground that she had no visible means of support, and was unsafe to leave at large.”

The *News* adds—

“This poor idiot paid the penalty of being bereft of her reason by remaining as a common felon in our city prison until Monday morning, whence she was then conveyed to the Police Office, where the Mayor and Capt. Brennan were presiding, and there placed in the dock, a smiling, trembling, harmless idiot in the midst of some unfortunate drunkards, a seeming felon in the eyes of the public, made so by the beneficent (?) lunacy laws of Ireland. When a fitting time arrived, Dr. Jackman's certificate was produced; the necessary certificate received a requisite double magisterial signature, and the poor woman, after about forty hours' imprisonment for being idiotic, was taken to the asylum. Could there be anything more monstrous conceived? Anything more fearfully unjust? An incident of the kind needs no argument to point its enormity. Why should one of God's creatures be thrust into a prison simply because he or she may be an idiot, with a large and costly asylum at hand which, we are told, is paid for by the ratepayers for such poor creatures, for their possible cure? Why should the fearful visitation of lunacy be rendered still more bitter to the friends of the afflicted being, by having him or her marched to prison, and kept there as a criminal for thirty-six hours? Surely there is nothing to prevent the adoption of the simple and fair process of admitting a lunatic to his or her peculiar asylum in the same way as a pauper is taken into the refuge prepared for him, and deserving paupers are not treated as criminals for being poor? If the relieving officer and the dis-

pensary doctor, who are always at hand, had the power of provisionally admitting in those cases, as the former officer has under the Poor-laws, what a large amount of injustice would be prevented; what a world of unnecessary trouble would be obviated? The governors, like the Poor-law guardians, meeting once a week, as they should meet, would have those provisional cases before them; the claims put forward on their behalf would be investigated: justice would be done, and a painful visitation mitigated as far as possible.”

### A Strongylus Expelled from the Urinary Passages.

A GENTLEMAN, aged sixty-three, says Dr. Amath Dubois, came (*Courr. Méd.*) to Vichy in 1869 with some curious symptoms—cold feet and hands, inappetence, nausea, acidity, and eructations. Liver large and hard, urine copious; sight unfeebled. In 1871 another season at Vichy with similar symptoms. He got much better when hæmaturia set in, with much sand and gravel in his urine. On 10th June, 1871, new hæmaturia to a considerable extent, in the midst of which were found several worms, which were recognised to be strongyli. At least forty were passed.

### Registration.

It is really too bad of the College of Surgeons and the Apothecaries' Company, to expect students to register within their walls. One registration is enough, and that of the General Medical Council is the only one necessary. We advise students to strike against college and hall. Let them only refuse in a body to comply with the stupid regulation, and it must be rescinded. The College of Physicians now gives a licence which is recognised as a qualification in surgery as well as medicine. It asks no registration, and armed with it candidates could offer their money at Lincoln's Inn and Blackfriars, without fear of rejection. To be obstinate would be to starve.

### Ergot of Rye in Port-Partum Hæmorrhage.

DR. TIBONE (*L'Indépendente*) mentions the case of a woman, aged thirty-seven of sanguine temperament, who came into hospital 17th April, and gave birth on the same day to an eight month's child, without any reason being given why she had been thus prematurely delivered. Half-an-hour after the accouchment, although the placenta came away naturally and complete, the uterus remained inert, and hæmorrhage came on. This was soon arrested by a dose of ergot of rye.

### Dispensary Work in Ireland.

IN the course of a sworn investigation held lately at Ballylady, near Walle, Dr. Hurley, a gentleman who had acted for a short time as a substitute for the local medical officer swore—

“The district is the most awful one I ever went into. I would not take £500 a year to do the duty, for it was eight o'clock at night when I finished the duty, and I travelled over fifty miles that day.”

THE *Practitioner* contains an editorial on the recent poisoning case at Melksham, which echoes the opinions already put forth in the *MEDICAL PRESS*, and condemns as unequivocally as we did the coroner, fully exonerating at the same time Dr. Meeres.

### Excessive Doses of Opium Tolerated by a Child.

THE following letter appears in the *Boston Med. and Surg. Journal*:—A case of morbus coxarius has recently come under my notice in a girl of eight years, suffering in the third stage of the disease, who takes one drachm of sulphate of morphia, in scruple doses, during the twenty-four hours, so tolerant is the system of the drug and so great is the pain. Never before this have I known so large an amount of the drug to be taken at once, in so young a person, without narcotism being produced. Yours very truly, M. L. BATES, M.D., Canaan, N. Y.

### Sewage.

THE great sewage question is exciting renewed interest. It is our privilege to place before our readers one of the most valuable series of reports ever issued. These we recommence to day, and in a few more numbers they will be complete. We have no hesitation in claiming for them the very highest place in the literature of the subject. Many of the facts therein made plain, have not yet received the notice they demand, and as stated at the beginning of these articles, the authority on which they appear is the very highest.

### A Voice from the Crowd on Medical Charities.

AN esteemed correspondent and contributor sends us a letter published in the *Nottingham and Midland Counties Daily Express*, and which he says was nobly written by a real workman. Touching as it does upon a subject of great moment to the general practitioners of this country, it appears to him to be worthy of republication in all the Medical Journals. Our correspondent adds:—"Such sound political economy and rare common sense deserve more than a passing record."

We extract a few passages from the honest workman's letter:—

I have long felt the degradation that is brought upon my class by the habit which we, as a body possess, of ignoring self-help and trusting in our hour of need to the efforts of the benevolent. The sublime sentiment which I have more than once heard expressed—"I will enjoy what I work for as long as I can, and when I can do so no longer the parish may do for me," is carried out in practice by thousands in our midst. . . . I do not hesitate to say that of the total of 18,994 patients who were the recipients of medical charity last year, 10,000 ought to have done and could if they would make provision for their medical needs, and that without encroaching on the necessities of life; nay, the means of securing those necessities would be increased in many instances, because the provision made would mean so much less spent in intemperance, which itself is the origin of very much ill health. . . . It is time something was done to open the eyes of working people to their degrading dependence on charity for relief in the hours of trouble. It is a dishonour; a foul stigma upon the whole of our class; it robs us of becoming dignity and proper self-respect. How can it be otherwise when we wilfully waste our own substance in wasting our health and then as dejected applicants solicit succour for its repair. Is it to be wondered at that we are so frequently looked upon as inferior beings when we lower ourselves daily and hourly by knocking at the doors of the well-to-do and prudent, and in the supplicant attitude of beggars crave aid and assistance on behalf of ourselves, when we have had every opportunity of proudly buying it? I wonder any persons

can so humiliate themselves, so degrade themselves, be so lost to their own manliness as can possibly, by any provision, secure help in sickness through their own efforts. I am aware there are too many who must depend upon charity for their succour; people so poor that pence are a considerable addition to their income, but they are a small minority compared with the great majority who reduce themselves to this same level of poverty and dependence, and against whom I make this protest. It is fearful to think that the spenders of seventy millions yearly in drink, besides what they spend in tobacco, are continually asking the aid of the benevolent; and what is more the very people who are the first to ask aid of the rich are the first to rail against their pride and tyranny, and to speak of them as oppressors.

### Morphia Valerianate and Tincture Gelseminum in Asthma.

DR. ANNANIAS W. SAWYER states in the *Journal of Materia Medica* that he has found in morphia valerianate a real charm, one or two doses producing in a very short time all the benefits derived from a certain emetic and expectorant. Relief is followed by much nausea and great prostration, but the respiratory organs are left cumbersome and free. The nausea and prostration last several days. He uses this powerful agent only when the usual remedies prove powerless, and "the mysterious giant gelseminum cannot break loose the suffocating grasp of this cruel monster." Lobelia, stramonium, gelseminum and all other expectorants and anti-spasmodics have failed in his hands, while the valerianate has in every instance promptly succeeded; but the effects of the remedy invariably make the patient think that he has paid "too dear for the whistle." Dr. S. gives medium doses of the valerianate uncombined every half hour until it acts as an emetic, and has never had to dispense more than two doses in any one attack.

### Disinfectants.

AN interesting meeting of the Royal Pharmaceutical Society of Brussels has been lately held, at which the subject of the disinfecting property of certain supposed disinfecting and antiseptic substances were discussed. M. Créteur has made many experiments, and he shows that nothing is comparable in effect to a mixture of sulphate of iron and chloride of lime in its action on organic putrefactive matter. He shows, by a double series of experiments on blood, the injurious action of foetid gases in the blood. Nothing is easier than to prevent animal decomposition by causing them to undergo the action of oxygen. He showed a piece of veal preserved in water for three weeks by this method.

From these experiments the author concludes that all substances capable of assimilating hydrogen products, or causing a formation of oxygen ought to be considered as disinfectants.

THE contest for succession to Oppolzer in the Faculty of Medicine of Vienna is divided between M. Kerner, known by his works on the "Motion of the Heart," and on "Fever and Tuberculosis," and M. Bamberger, Professor at Würzburg. According to the *Vienna Medical Gazette*, the first of these candidates is certain of success, as Professors Skoda and Rokitansky, who are in the confidence of the Minister of Public Instruction and of the Emperor, are favourable to his candidature.

### Vaccination.

THE Council of Public Hygiene of Paris, consisting of an eminent quintaine, Beaudé, Bouchardat, Michel Lévy, Vernois, and Delpéch, have issued a report on the recent small-pox epidemic. They say the reproaches against vaccination are unjust in every respect. It has, in no respect lost its power of preservation from small-pox. The only method of putting an end to epidemics of this disease is to effect the greatest possible number of vaccinations. Re-vaccination practised with the necessary precautions presents no danger whatever. It ought to be effected at ten or fifteen years of age at latest, and repeated every four or five years, as long as it does not produce a regular pustule.

Patients attacked with small-pox should be completely isolated in special hospitals, far from centres of population.

### Carbon Bisulphide, Rhigolene, and Olæum, Menthæ, Piperitæ, as Local Anæsthetics.

DR. S. R. NISSLEY, of Pemberton, Ohio, says he has been in the habit of using the bisulphide of carbon as a local anæsthetic for several years in facial neuralgia, hemicrania, odontalgia, and lumbago, the speedy relief it affords is almost instantaneous. He puts a pledget of cotton into a wide-mouth bottle, saturates it with the bisulphide and applies it to the painful part, as soon as the patient complains of smarting sensation, he changes the bottle, carefully following the course of the principal nerve that seems to be involved. He has formed a combination of rhigolene and the oil peppermint as a local anæsthetic most successful in a number of neuralgia cases; recently he has been in the habit of adding an ethereal collodion to the compound, and reports in the *Journal of Materia Medica* that this combination is a specific, which will under almost any circumstance, when the part is accessible, relieve the patient instantaneously.

ACCORDING to the *Standard's* Correspondent, the sanitary state of Berlin is a great danger, with cholera not far off.

THE noisy set of students this year seem to have gone to St. Thomas's and Guy's had peace. We may admit, however, that at St. Thomas's they were not well treated.

THE *British Journal of Dental Science* contains an appeal on behalf of the widow of the late Horace Wells. We hope it may be successful.

THE *Globe* last week had several articles of professional interest. One on medical charities is deserving of special mention.

ACCORDING to the *South London Press* the new system adopted at St. Thomas's Hospital for the ventilation of the building, is a failure.

THE first meeting of the 99th session of the Medical Society of London, will be held on Monday, October 16th, at 8 p.m., at the Society's Rooms, 32a George street. Mr. Gay will read a paper on "Crural Venosity."

SEVERAL of the hospitals commemorated the opening of the schools on the 2nd inst., by a dinner.

THE Director-General of the Navy is to be a member of the senate of the Army Medical School at Netley. Quite time!

PROFESSOR KURSTEN of Vienna, has been suspended from his functions, because he had rejected 90 out of 102 candidates in his botanical examination.

IT is reported that the governors of Bethlehem Hospital are about to build a branch establishment for insane and convalescent patients at Witley.

THE new number of the *Journal of Mental Science*, opens with the address of the President of the Psychological Association, of which we have already given an abstract.

THE cholera epidemic at Constantinople may now be considered at an end. On Friday there were only three cases. The deaths during the last few days from the disease were 150.

THE Small-pox Hospital inquiry still "drags its slow length along" to the utter disgust of the public. It seems as far off as ever from a conclusion. When both sides have been heard it will be time enough to consider its lessons.

THE "Lectures on Diseases Peculiar to Women," by Dr. Athill, which recently appeared in this Journal, have been revised by the author, and are now published in a separate form by Fannin and Co., Grafton street, Dublin.

PROFESSOR ATTFIELD has revealed an attempt to poison through the post. A packet of tea was sent through the parcel's post to a lady, who concluding that it was as an advertisement and that a letter would soon follow, rashly tried it. Every one who tasted it suffered.

THE feud between the medical officers and the Southampton Board of Guardians appears to have not one whit abated. The appointment of Mr. Archer, homœopath, in lieu of Dr. Griffin resigned, had not been confirmed by the local Government Board at the time of going to press.

IN London, according to the last weekly returns, there were 1,390 deaths registered, being five above the average of the corresponding week in ten preceding years. Deaths from small-pox and diarrhoea show a satisfactory rate of diminution as compared with preceding weeks.

THE Austrian Minister of Public Instruction has arrived at a remarkable decision. He is about to issue to the professors of all the Austrian Medical Schools, a circular requesting them to transmit to him at the end of each year, a statement of the work which they had done during the year, either as *savants* or as professors. The note is to include all their practical labour as teachers, their laboratory work, their researches, and their publications either in books or journals. These notes will be compared, and on them promotion will rest.

## Hospital Reports.

### CITY OF GLASGOW FEVER HOSPITAL.

#### *Post-febrile Insanity, complicated with Hysteria, cured by Cold Baths.*

(Under the care of DR. RUSSELL.)

THE resident medical officer, Dr. William MacEwen, M.B., reports in full, in the *Glasgow Medical Journal*, an interesting case of a girl, *æt.* fourteen years, who was admitted to the City of Glasgow Fever Hospital, Belvidere, on the 26th February, 1871, insensible, delirious, muttering, and covered with a copious typhus rash, apparently in the ninth or tenth day of typhus. She continued in a low state, being sleepless and delirious, passing her motions in bed, having a feeble pulse, ranging from 120 to 132, until the 1st of March, when she began to improve. Convalescence was so slow and protracted that she relapsed on the 28th March, became delirious, very violent, and attempted to get over the window. She had to be fed through the nose much against her will, and made but little progress.

On the 1st April her pulse was 88 and good. She had slept none the previous night. Her bowels had been freely moved. Showed her tongue partially, but on desiring that it should be protruded further, she withdrew it and shut her mouth firmly. After the usual dose of morphia, she slept for three hours.

A few days afterwards it was thought advisable that the hysterical element, which seemed to preponderate, should be treated, and, with this view, she was ordered a cold plunge-bath. She resisted going into the bath; but after it had been given to her she walked quietly to her bed, and fell sound asleep. When she awoke she took a meal for the first time since the 28th March (nine days).

On the 7th the cold plunge was repeated. She slept soundly the whole of the following night, and took a hearty breakfast in the morning. The cold plunge-bath seemed to have a sedative effect, as she always slept soundly after it. The feeding by the nose was no longer continued, as she took her food with eagerness.

On the 8th, having slept soundly all night, she had another cold plunge, after which she ate well, and spoke sensibly to the nurses for the first time. At the visit she showed her tongue, gave her hand when asked, and answered intelligently. She ate anything that was given her with great eagerness, and was soon discharged cured.

#### *Case of Acute Glanders in man.*

(Under the care of DR. J. B. RUSSELL.)

THIS disease is not often observed in man. We are glad to take from our Glasgow contemporary full particulars of this case, very carefully reported by Mr. John Weir, M.B., Extra Assistant.

M. C., *æt.* thirty, omnibus driver, was admitted to the Belvidere Fever Hospital June 21st, 1871, complaining of "soreness" of his body—no part being entirely free except the joints, in which there was neither pain nor tenderness. Skin was bathed in perspiration, and without eruption. Appetite slightly impaired. Tongue moist, unevenly coated with a thick white fur.

Illness commenced eight days previous to admission (*i.e.*, 13th June) with a cough and spit, to which was added, three days after, pain in the right side at the lower ribs. Medicine was given, which relieved the cough, and patient did not stop work until the 18th, when he returned from the stables at ten a.m., complaining of the pain in his side, and adding that he had received a kick from a horse "between the thighs." A poultice applied to the side gave him relief, and he made no further complaint either of this or of the kick from the horse. On

the 20th he was still ailing, and the doctor who saw him advised his removal as a case of relapsing fever.

June 22nd (10th day)—Taking solid food, and making no complaint, excepting of the soreness of his body.

23rd (11th day)—No mark of the kick of the horse could be discovered. No improvement. A swelling was noticed in the calf of the right leg while sponging him. More swellings were discovered on examination, and also a blush of inflammatory redness over the metacarpophalangeal joint of little finger of left hand.

24th (12th day)—A small peculiar red eruption began to make its appearance on the chest and arms. Redness on little finger was more marked, and in the centre of it a small black gangrenous spot had formed. Tongue was thrust out in a tremulous manner. Pulse 108, full and strong.

25th (13th day)—Pulse 120; temp. in axilla, 105°. Eruption more distinct, with broad angry areola, and becoming pustular. Dr. Russell was asked to see the case, and suggested that it was glanders. The respiration was impeded, and examination of chest revealed dulness in upper third of left back, and lower half of right back. He was still taking fluid food in the shape of beef-tea, stimulants, &c. Urine was passed in abundance. Eruption now consisted of pustules scattered over the chest and arms, varying in size from that of a pinhead up to that of a pea. A few were elongated, or of irregular outline, as if formed by the coalescence of several pustules. The inflammatory blush on little finger had reached one and a half inch above metacarpophalangeal joint—the gangrenous spot being now quarter inch long by one-eighth inch broad. On the forearm were four subcutaneous tumours, one about one-and-a-half inch above wrist, and as large as a walnut, without any general signs of inflammation; another, flattened and red, one-and-a-half inch long by half inch broad, situated on the ulnar side of the inner surface of arm, midway between wrist and elbow; and at a corresponding point on the radial side one similar of the size of a pigeon's egg; and the fourth over the head of the radius, equal in size to that on the ulnar side. On the upper arm were three tumours, of the size of a walnut, slightly raised above the surrounding tissues; two situated midway between the elbow and shoulder, one on the outer, and the other on the inner side, the third being on the anterior aspect of the shoulder, this one alone having slight redness on its surface. On the forehead was a rounded tumour, of the size of a walnut, angry red on the surface, and fluctuating on pressure. Over the course of the upper part of nasal duct of left side there was a slight swelling, which appeared to close the duct. There was a considerable quantity of glutinous mucus adherent about the eye. The face, as a whole, was full and congested, and the aspect highly febrile. There was a red blush on the little finger of right hand, similar to that on the left, but without the gangrenous spot. On the right arm, from the wrist to the shoulder, were tumours in the same positions as on the other arm, but not as far advanced. The calf of the right leg was livid, and also presented several indurations. In the thigh, also, along with general swelling, was a number of small tumours. On left leg tumours and swelling much the same, but not so well marked.

26th (14th day)—Patient much weaker, bathed in a clammy perspiration. Pulse 132. Though quite helpless, he raved loudly. Intelligence became gradually obscured, and he died quietly at five p.m.

*Post mortem examination.*—*External appearances.*—Body muscular and well-developed. On anterior surface of chest and shoulders, and also on external aspect of both arms, especially the left, there is a peculiar eruption. It consists of flattened pustules, which vary in size from a little larger than a pin's head up to that of a horse bean. These are situated superficially in the skin, being covered for the most part simply by epidermis. The fluid contained is more watery than pus. In addition there are several subcutaneous indurations, generally about the

size of a pigeon's egg, and situated in various regions of both upper and lower extremities. The natural outline of the limbs is strangely broken by these projections.

*Heart* is normal.

*Lungs*.—On surface of left lung there are a few spots of sub-pleuritic hæmorrhage, but beyond œdema there is nothing remarkable. In right pleural cavity there is a quantity of yellowish fluid, and on the surface of the lung a layer of pretty firm lymph. There are also here several spots of sub-pleuritic hæmorrhage. In both lungs the bronchial tubes are somewhat congested.

*Liver*.—Somewhat fatty, but otherwise normal.

*Spleen*.—Slightly enlarged.

*Intestines*.—The small intestines are normal. In the large intestines there is considerable congestion and exudation towards the lower extremity.

*Head*.—Calvarium extremely thick, and the dura mater very firmly adherent, especially on the right side. Brain and its membranes somewhat congested, but otherwise normal.

On examination of the swellings referred to as existing under the skin, they are found to be abscesses filled with thick creamy pus. They are of various sizes, and appear to be situated mainly in the muscles, but some of them extend outwards, so as to come in relation with the under surface of the skin. Some, however, actually are in the skin only. These abscesses are very abundant, as is shown by the circumstance that the knife plunged vertically into almost any part of the body comes on pus in some part of the tissues penetrated. The abscesses were all lined by a distinct pyogenic membrane.

In the right knee joint the synovial fluid is very much increased in quantity, but still glairy. The shoulder and ankle joints are healthy.

Dr. Russell says that Dr. Weir took great pains to trace this case to an admitted case of disease in the horse, and he had no hesitation, after the *post-mortem* examination, in certifying the cause of death to be glanders. Experiments on animals have since confirmed the diagnosis. Matter from the pustules on this man's body was inoculated into the thigh of one cat, and blown into the nostrils of another. They both speedily showed signs of illness. In the former the symptoms were much the more acute, and ended in death in twelve days. The latter lived twenty-three days. Superficial sores were found in both animals, evidently originating in deposits of cheesy granular matter such as Virchow describes as characteristic of the local manifestations of glanders, both in animals and in man. With regard to the experiments on animals, Dr. Russell mentions that rabbits were found not to be susceptible. Dr. MacEwen, resident medical officer at Belvidere, has instituted a series of experiments on cats and dogs with this animal poison.

#### SANITARY STATE OF AN IRISH COUNTY TOWN.

KELLS, in the County Meath, is one of the very few Irish county towns whose local boards has the prudence to provide a medical officer of health, and the town commissioners accordingly appointed to that office, Dr. Halton, who in one month has furnished a statement of a very valuable and very alarming character. He describes the condition of the town succinctly, and as we have no reason to hope that other provincial Irish towns are even as well provided with sanitary arrangements as is Kells, we recapitulate Dr. Halton's summary as an illustration of the condition of a sample Irish town under the control of a local government. Dr. Halton says:—

"I find that the sleeping population of Kells every night consists of 2,796 persons. These are lodged in 503 houses, giving an average of a fraction over  $5\frac{1}{2}$  persons to each house.

"I will divide the houses into three classes, viz.:—First-class houses, or houses having a room to each inmate—of these there are 101; second-class houses, or houses

which have over two rooms and under six—of which there are 135; and third-class houses, which have only one room each, or, if more, is so over-crowded as to render it dangerous to health—of these there are 272, including the houses set in tenements, which may be looked on as the worst of the class.

"The third-class houses, with the exception of the houses set in tenements, with which I will deal separately, are, for the most part, one-roomed cottages, each containing a whole family, with all its belongings. Sixty-two of these houses have no back door, and no yard; consequently, all the refuse and filth of the house must go into the street. Ninety-seven houses, though having a back door, have no accommodation whatever in the yard, which is thus, from the necessity of the case, covered with scattered and evil-smelling refuse.

"The number of those houses that have animals lodged with the family is 38, with an animal sleeping population of 46 pigs, 3 mules, 4 asses, and one pony. In the majority of these places the smell in the day time, with the door open, is very bad; at night, when the family are all in bed, with the door shut, one would say the stench must be intolerable.

"This is bad enough; but I have no hesitation whatever in saying, that the tenement houses are, in many cases, worse still.

"There are 15 of these dens in the town, with an average population of 12 in each, largely increased each night by a fluctuating number of casual lodgers, and in four of them the permanent inmates number, respectively, 22, 21, 19, and 22.

"It is difficult to speak with calmness of the state in which these poor people are obliged to live—a family, and sometimes two, to each miserable room; the floors coated with dirt; the windows closed up with bits of tin or board, or stuffed with rags, thus excluding both light and air; the staircases rotten, tottering, and unsafe; in one case the lobby is perfectly unprotected by bannisters, and the wretched mud or plaster partitions between the rooms shake on the least push.

In one of these houses, where seven families reside, there is no accommodation whatever, except an open sewer reeking with filth in the yard common to the house itself, and to the inmates of three wretched cottages behind it.

In another of these houses all the filth of the house is thrown out of the back windows, and forms, in a plot ground immediately behind, which is too small to call a yard, a horrible open dunghill."

Dr. Halton also calls attention to the practice of butchers in slaughtering the animals in their dwelling houses. This is most injurious to the health of themselves and their families, for the blood, no matter what amount of cleanliness is used, soaks through the ground, and there putrefies, sending forth most offensive odours.

The remedy is simple and obvious—namely, the erection of a proper public abattoir in some convenient site close to the town, which could be used by all, and which might be erected at a trifling expense.

We wish we could say that Dr. Halton was guilty of exaggeration, or that his town is not a fair sample of Irish towns generally. We believe Kells, if it differ at all from similar towns, is in a better condition of sanitation.

#### CHINA—MEDICAL MISSION-WORK.

ALTHOUGH foreign missionary work has been blamed by many during the last few years for political complications arising in civilised parts of the world, yet there is one form of missionary effort which is certainly not open to this charge, viz., medical mission-work. We refer to the facts detailed in the reports of several of the hospitals in foreign parts in connection with the London Missionary Society, but we derive our warrant for the above assertion from the particulars given in the ninth annual report for 1870 of the Pekin Hospital (under the charge of Dr. Dudgeon). It is not difficult to understand that European remedies, when applied by skilful English practitioners, will often cure not only severe and grave dis-

eases, which, in places like China, are incurable, if only because the native practices are such as to prevent recovery; but also a multitude of simple ailments, which, have generally an unnecessarily lengthy duration, which would be avoided if the cases were left entirely to nature. This greatly impresses the native who has something tangible to show in himself in proof that the doctor's mission is one of peace and utility. His confidence is by-and-by won, and the way more readily opened to the operation of higher civilising influences. The report of the Pekin Hospital is both instructive and amusing, as it affords many illustrations of the prejudices of the Chinese. The year 1870 was an eventful year. The uneasiness among all classes caused by the sad events at Tientsin in June also affected the attendance at the hospital, although about eighty miles distant. The number of patients in 1870 was 11,061, against 14,420 in 1869. But indications of returning confidence have shown themselves, and the people now seem more friendly than ever. There is one event, however, which has advertised the hospital widely, and given it an improved status, viz., the posting all over the city in December last of a huge placard, setting forth that a great man had been saved from death by the physician of the hospital. The proclamation ran thus:—

“Wu Yun Chung, of the Red Banner of the Han Chiun Tsiang Camp, in order to make known the following notice:— In the 9th year of T'ung Chih, 4th month, and 2nd day, at the review ground of my own banner, at the time of review, the thumb, a portion of my forefinger, and palm of the left hand, were blown off by the explosion of my gun. Immediately I became insensible, and the flow of blood could not be stopped. Doctors and drugs were of no avail. Thereupon I was carried to the English Hospital, situated on the east side of the street to the north of Tan p'ai leu, and I prayed the great venerable English surgeon to cure me, who immediately stanchied the blood, relieved me of the pain, and by the evening I could eat and drink. On this account I retained life. I cannot divine any method of recompensing such favour. I therefore have resolved to issue this public notification, that all men may know that the merit of the venerable doctor—in saving and giving life to men—is unlimited.”

This announcement has been followed by more placards by grateful patients, a practice imitated, it seems, by the members of the native faculty for the purpose of self puffing. There is a good deal of resemblance in this between the practices of our own country and those of China. Dr. Dudgeon has been taken into the confidence of some great ones of the city—no less awful a personage than the President of the Board of Punishment, and also the family of the Chief Secretaries of State. So European physic is progressing in Pekin. One case was that of a young lady who had a bad leg, baffling the native doctors, and who could not get married because of it. She was cured in two months, to the astonishment of the friends; and this led to the visit of many respectable people (out-patients). *Prince Pulin, 500 miles off Pekin, sent some of his retainers to the hospital for a supply of cough mixture.* No one can doubt that the institution is doing much to dispel many of the absurd prejudices that exist, and we are glad to find proofs in the statement that the Chinese are showing an increasing desire for a better acquaintance with foreign ideas as regards medicine, and also appliances of all kinds, and matters of science generally. The Prince, a frequent visitor to the shop lately opened for the sale of *anti-opium pills*, in connection with the hospital is said to have said, after being shown over, “All that is wanted by our people is to know more of you foreigners; the more we know of you the better we like you, and we cannot know you and not like you.” Some of the rich Chinese have ordered from England many appliances which, a short time ago, they would never have dreamt of about the pill-shop. The habits of opium-eating and smoking are difficult, of course, to give up, but numbers of people do manage to, and they are aided materially by the pills, a compound of henbane, gentian, camphor, quinine, cayenne pepper, ginger, and cinnamon, with Castile soap and syrup. These pills relieve the craving and distress felt on relinquishing the opium. Some thankful patients felt the doctor in curious predicaments by the form of their gratitude. The Mongols are very grateful. Pheasants, butter, and a horse made up one present offered to Dr. Dudgeon. But on all occasions it is necessary to accept first a *haddock*; or white silk handkerchief, blessed by the living Buddha or Lamas, who recite prescribed prayers, and they only acquire supernatural virtue after this ceremony. Unless the haddock is accepted, no presents can be given. The actual practice of the native

doctors is referred to in several particulars, but we only refer to one. It indicates the little chance which the sick have of recovering when in the hands of native talent. In the use of mercury, the Chinese doctors surpass the most *outré* treatment even of old Indian doctors. *An ordinary prescription is 180 grains of saltpetre and 300 grains of calamel for one dose.* The appearance of one poor patient who applied at the hospital, after taking half this dose, passes description. Her tongue was 1½ inch thick, the gums and jaws of unusual size, the mouth could not be shut, and the tongue hardly be contained in it; the chest and throat were greatly swollen, and swallowing impossible. Death took place in a few days. An individual dosed with mercury always has a pencil tied in the mouth at night, like a bit, to help the flow of saliva, the poison of the mercury, as it is called.

## Literature.

### LIFE AND THE EQUIVALENCE OF FORCE.\*

This is a very remarkable pamphlet, and, if we mistake not, one which will be extensively read by physiologists and persons who occupy themselves with physical science, a constantly increasing number, in our age of what is called *positive science*. Physicians will do well, too, to read a work which will perhaps, for the first time, let them know something about what is meant by protoplasm, and how Force is defined in modern times. Chapter II. of the work before us treats of the nature and definition of Force, a former pamphlet having given a most interesting account of the history of the discovery of the mechanical equivalent of heat. According to Mayer, the word force is used in two different senses: first, any pressure or effort of an inert body to change its state, and, second, the term is applied to that pressure into the space through which it acts. Mayer says the second definition should alone be retained. “Force is that which is expended in the production of motion,” says Mayer. Force is merely an affection of matter, and is inconceivable as separated from matter. The potential energy of a raised weight may just as well be called unbalanced falling force. Matter, says our author, without force would be a true state of chaos. It would then have no aggregation, nor any of the secondary properties which that involves. Since the publication of Faraday's paper, Waterston, Challis, Maxwell, Glennie, and others, have shown mathematically that all the facts of gravitation, as well as of other attractions and repulsions, are susceptible of explanation quite as satisfactorily by the supposition of external pressure on the particles of matter as by the prevalent one of attractive forces within them. “As a familiar illustration of the relations of the properties and forces of matter, we may compare the former to the bricks and the latter to the mortar in the building of a house. Without the mortar the bricks cannot be made to take or retain the required form; but when the mortar is once used, its faculty is lost, and it cannot be used again without a fresh store of moisture and other qualities being given to it. So likewise with the forces, for in all work done some part of them is transformed into heat and dissipated; but the properties are like the bricks, which remain there in their pristine completeness.”

In Chapter III., on the nature of life, the author, one of the editors of “Fletcher's Pathology,” passes a very high eulogium on that writer, who dissents from the opinions of the large party who hold that the proximate principles are associated by common chemical affinity, and still liable to be affected by its laws. The author, in company with Fletcher, holds that in the living body the elements obey laws not merely modified, but entirely different from those of ordinary chemical affinity. To the

\* “Life and the Equivalence of Force.” Part II. Nature of Force and Life, containing the Harmony of Fletcher and Beale. By J. Drysdale, M.D. Holden, Liverpool. 1871. Pp. 204.

alleged facts in favour of abiogenesis, he remarks that no doubt some unsuspected source of fallacy has been present. No chemical phenomena, in the ordinary sense, take place in living matter, *i.e.*, there are no oxidations, nor formations of acids or alkalies, nor salts, nor of albuminous, fibrinous, fatty, gelatinous, or other matters, and these take place only in the act of passing into the dead state. The science of physiology is entirely different from that of chemistry, and nothing is to be judged of in relation to living matter according to its chemical nature, but solely as pabulum or stimulus, unless inert or a diluent, like water. To the living matter there are no acids or alkalies, no solvents nor constringents such as tan, no fats nor soaps, no ferments nor catalytic agents, no sugars nor alcohols: none of these things to act in the least like the way they act on dead matter,—only pabulum and stimuli. Dr. John Brown, in 1780, raised stimuli to the position of an essential part in what he showed to be an action or process; and our author tells us that Fletcher was deeply imbued by this idea. The true tests of the nature of the living matter are the reactions it displays with external agents, in the form of pabulum and stimuli; and these reactions are nothing else than life itself. A large proportion of the bulk of organised beings is not really living, but consists of chemical compounds as we find them after death, and we have thus always before us a mixture of dead and living matter. It is the distinguishing property of fibrine to undergo spontaneous coagulation; but no such coagulation takes place in muscles till they are deprived of their vitality, when they rapidly become stiff. It is to this cause (says Fletcher), and not to the contraction of the muscles, that the rigidity of the limbs, which soon succeeds death, and continues till the putrefaction process has commenced, is to be attributed. Dr. Beale, in his "Oxford Lectures," says that the chemist can tell us nothing about the molecular condition or chemical composition of the living matter. The albumenoids are no nearer life than the inorganic materials, except in so far as they form a pabulum more easily assimilated by some organised beings. Beale says, "a cell, or rather transparent structureless matter, does, without any apparatus or machinery whatever, and at a lower temperature and in a marvellously small space, and with marvellous speed, much that the chemist cannot achieve, with all sorts of complex apparatus."

In Chapter IV. the author speaks of the anatomical seat of the living matter, and shows how Fletcher comes to the conclusion that vitality does not reside in the muscles, nor in the nervous system as a whole, but exclusively in the grey matter of the ganglionic nerves alone; and that it is only in virtue of the possession of this matter, universally diffused and intimately interwoven with its texture, that any tissue or part possesses vitality. In 1835, a living moving substance was discovered by Dujardin in the lower animals, which he called sarcode. Afterwards, a similar substance was found by Von Mohl in vegetable cells, and named protoplasm. In 1861, Dr. L. Beale's lectures, at the College of Physicians, proclaimed a discovery, which the author thinks is equal in intellectual merit, if not superior, to the discovery of the circulation of the blood. Beale says, "The name I propose to give to the living or germinal self-increasing matter of living beings, and to restrict to this, is Bioplasm . . . a living, white blood-corpusele is a mass of bioplasm." Our author thinks, with Dr. Sharpey, that the term protoplasm will still be retained to express Beale's germinal matter. As the result of years of independent observation, Beale came to the conclusion that life or vital power is not generally diffused over different tissues or organs, but is restricted to one kind of matter alone in all living things, both animal and vegetable, from the highest to the lowest. Germinal matter is always transparent, colourless, and perfectly structureless. There is a period in the development of every tissue and every living thing when there are actually no structural peculiarities whatever (says

Beale); when it would not be possible to distinguish the growing, moving matter which was to evolve the oak from that which was the germ of a vertebrate animal. There are masses of bioplasm to form nerve, others to produce muscle, others glands, and so on, all of which have been derived from one common mass. It appears that Fletcher and Beale disagree about theology; but it is not the part of a medical periodical to take part in that controversy, and so we do not propose to follow our author in this part of his subject.

Much of the matter contained in the pamphlet will, we feel sure, be new to many of our younger readers, and we can most conscientiously recommend all of them who are devout believers in the chemical school of Bence Jones to peruse this interesting work. Trousseau used to say, that he never had had one hint in therapeutics from any chemical theory, and if the dictum be true, the sooner we grant it practically the better for our patients and for our own intellects.

### THE SYSTEM OF MEDICINE

WE are glad to announce the appearance of the third volume of the able and encyclopædic work edited by Dr. Russell Reynolds\*, to whom the thanks of the new generation of practitioners is due for the labour he has bestowed upon, and the skill with which he has selected, his collaborations. The publishers, too, receive a word of congratulation for the manner in which they have brought out the best cyclopædia of medicine of the time. In this notice we cannot pretend to do justice to the many original and complete essays here brought together, and we shall, as in the case of former volumes, take opportunities as they arise to refer to them individually. The following is a complete list of the contents:—

- Diseases of the Mouth, by Charles E. Squarey, M.B.
- Diseases of the Fauces, Pharynx, and Esophagus, by Chas. E. Squarey, M.B.
- Enteralgia, by John Richard Wardell, M.D., F.R.C.P.
- Enteritis, by John Syer Bristowe, M.D., F.R.C.P.
- Obstruction of the Bowels, by John Syer Bristowe, M.D., F.R.C.P.
- Ulceration of the Bowels, by John Syer Bristowe, M.D., F.R.C.P.
- Cancerous and other Growths of the Intestines, by John Syer Bristowe, M.D., F.R.C.P.
- Diseases of the Cæcum and Appendix Vermiformis, by John Syer Bristowe, M.D., F.R.C.P.
- Colic, by J. Warburton Begbie, M.D., F.R.C.P.E.
- Colitis, by J. Warburton Begbie, M.D., F.R.C.P.E.
- Dysentery, by J. Warburton Begbie, M.D., F.R.C.P.E.
- Diseases of the Rectum and Anus, by Thomas Blizard Curling, F.R.S.
- Intestinal Worms, by W. H. Ransom, M.D., F.R.S.
- Peritonitis, by John Richard Wardell, M.D., F.R.C.P.
- Tubercle of the Peritoneum, by John Syer Bristowe, M.D., F.R.C.P.
- Carcinoma of the Peritoneum, by John Syer Bristowe, M.D., F.R.C.P.
- Affections of the Abdominal Lymphatic Glands, by John Syer Bristowe, M.D., F.R.C.P.
- Ascites, by John Syer Bristowe, M.D., F.R.C.P.
- Hepatalgia, by Francis Edmund Anstie, M.D., F.R.C.P.
- Congestion of the Liver, by W. C. Maclean, M.D.
- Jaundice, by Edward Goodeve, M.B.
- Biliary Calculi, by Edward Goodeve, M.B.
- Suppurative Inflammation of the Liver, by W. C. Maclean, M.D.
- Gangrenous Inflammation of the Liver, by W. C. Maclean, M.D.
- Chronic Atrophy of the Liver—Cirrhosis, by Edward Goodeve, M.B.
- Acute or Yellow Atrophy of Liver, by Edward Goodeve, M.B.
- Fatty Liver, by J. Warburton Begbie, M.D., F.R.C.P.E.

\* "A System of Surgery." Edited by J. R. Reynolds, M.D. Vol. II. Local Disease (continued). London: Macmillan and Co. 1871.

Cancer of the Liver, by J. Warburton Begbie, M.D., F.R.C.P.E.

Hydatid Disease of the Liver, by J. Warburton Begbie, M.D., F.R.C.P.E.

Diseases of the Pancreas, by John Richard Wardell, M.D., F.R.C.P.

Diseases of the Larynx, by Morell Mackenzie, M.D.

Emphysema of the Lungs, by Sir William Jenner, Bart., M.D. Lond., D.C.L. Oxon., F.R.S.

Asthma, by Hyde Salter, M.D., F.R.S.

Phthisis Pulmonalis, by J. Hughes Bennett, M.D., F.R.S.E.

Cancer of the Lungs, by Hermann Beigel, M.D.

Pneumonia, by Wilson Fox, M.D., F.R.C.P.

Syphilitic Affections of the Lungs, by Wilson Fox, M.D., F.R.C.P.

Brown Induration of the Lung, by Wilson Fox, M.D., F.R.C.P.

Cirrhosis of the Lungs, by H. Charlton Bastian, M.D., F.R.S.

A pneumatosis, by Graily Hewitt, M.D., F.R.C.P.

Bronchitis, by Frederick T. Roberts, M.D.

Pleurodynia, by Francis E. Anstie, M.D., F.R.C.P.

Pleurisy, by Francis E. Anstie, M.D., F.R.C.P.

Hydrothorax, by Francis E. Anstie, M.D., F.R.C.P.

Pneumo-Thorax, by Francis E. Anstie, M.D., F.R.C.P.

At present, we are content to note a few points that strike us as we give a preliminary survey, and urge all who can afford it to place the work on a handy shelf in their libraries.

First of all, we may tell our teetotal friends that there is much here to engage their attention. The use of alcohol in disease is discussed, like all other questions, in a truly scientific manner, and we hope they will not neglect to examine the arguments put forward—some of them, in our opinion, quite unanswerable. We may thus observe that on the subject of pneumonia, which is treated in a masterly manner by Dr. Wilson Fox, much is said to confirm the faith we imbibed from the late Dr. Todd; and those who have indulged too freely in condemnation of that enthusiastic teacher's doctrines would do well to digest the facts here arrayed.

On the other hand, turning to diseases of the liver, we find that Dr. Goodeve still adheres to the old, we had almost written exploded, notion that cirrhosis is almost always caused by the abuse of ardent spirits. We must enter our *caveat* against the acceptance of this time-honoured dogma, and confess that it is not in harmony with the latest clinical and pathological investigations.

Speaking of cirrhosis reminds us that Dr. Wilson Fox does not admit the existence of cirrhosis of the lungs—although we are at a loss to know why.

Emphysema is a word which we fancy is much abused, and therefore we look with interest to what Sir William Jenner writes about it. His essay is a model. What is really known about it is told with that ease and simplicity which characterises the great teacher, and in perusing this, we sit at the feet of our master, and rejoice that his spell is as powerful as ever. Everyone ought to read this essay, if he wishes to understand emphysema.

Dr. Anstie desires to see paracentesis thoracis more frequently employed, and we confess that in this he represents the tendency of modern practice. We listened last year with much interest to a discussion on this point at the Medical Society of London, especially as we at the time were treating effusion into the chest, and also had been called in long after the operation had been resorted to. Much is to be said on each side. Early operation, no doubt, is very attractive; still there are few who will not feel some hesitation. It is a question which we think should be still further investigated.

The essay on "Diseases of the Rectum and Anus," by Mr. Curling, F.R.S., is one for which the author's name is a sufficient guarantee. He is the very first authority on this subject, and as one of the most enlightened surgeons of the age his teaching will be received as that of authority.

Dr. Hughes Bennett contributes the essay on "Phthisis,"

which will be read everywhere with the deepest interest. It is unnecessary to particularise his views, which are well known, or to say that he inculcates them with great ability. In spite of his efforts, and that of the numerous band of able men who are giving their best time and attention to the study of the disease, there still remains much to be done. If, notwithstanding the melancholy returns of the Registrar-General, phthisis is as fascinating a study as ever, need we wonder that diverging opinions are abroad, or despair of some day coming to a better knowledge?

To-day space fails us for further particulars. In selecting these essays we do not pretend to do them justice, nor do we imply that the others are not equal. We take the subjects that most interest first, and may frankly confess that these are all we have yet looked over; but the book we shall keep in readiness for perusal, and have no doubt that we shall learn much from it. We close this brief notice by expressing our satisfaction that a fourth volume will be added to complete the work. The publishers have done well to bring out this at once. Contributors should hasten their work. They alone seem to have delayed it. The editor and the publishers we thank for their efforts, and may remark that it is owing to the dilatoriness of some contributors that the volume was not out earlier.

### HAMMOND'S NERVOUS DISEASES.

A COMPLETE treatise "On the Diseases of the Nervous System," from so accomplished a physician as Dr. Hammond, is sure to be widely read. It appears as a fine 8vo volume\* of nearly 800 pages, and is worthy of the author's reputation. He classifies the nervous diseases according to the pathological changes on which they depend, and this involves some change of terms in common use, but will probably be widely accepted as a rational plan. Accordingly, we have five divisions of the work—1. Diseases of the brain; 2. Of the spinal cord; 3. Cerebro-spinal diseases; 4. Disease of the nerve-cells; 5. Diseases of the peripheral nerves. The pictures of disease and the general symptoms are admirable, and will go far to make the work popular, and the treatment is rational. If we wished to find any fault it would be with the sections on diagnosis, which, perhaps, might have been a little more full. It is on diagnosis that the busy practitioner is often anxious to turn to a work that has pleased him in perusal—should obscure cases puzzle him; and we should therefore have been pleased had Dr. Hammond made more room for this by abridging elsewhere. Still, we ought to be satisfied for so practical a work—founded on the careful study of many hundreds of cases. Dr. Hammond's views are explained with general perspicuity, and if we do not always agree with him, we feel that his work is one that all may profitably study. It gives a readable account of the latest views of the pathology of the nervous system, and in following its recommendations the practitioner is guided by a most able and learned physician.

## Correspondence.

### DIVINITY v. PHYSIC.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have often and often admired how pertinaciously our clergy try by any and every means to obtain funds to support their widows and educate their sons and daughters, and how very gratifying it must be to their feelings to find that friends, and willing friends are never wanting; but when I look at the "Faculty" and see what they are not doing and could do, I feel inclined to say that "he is a slothful man that looketh not after his own house." I believe there is a society for the relief of widows of medical men, but I fancy it must be upon a

\* "A Treatise on Diseases of the Nervous System." By William A. Hammond, M.D. New York: D. Appleton and Co.

very small scale, besides, one stands a chance of being "black-balled," as one must send in his name for scrutiny before admission. What I am about to propose will remove all such objections, because it will embrace the entire profession. I believe there are about twenty-five thousand medical men in England, and I propose to establish a fund to which every medical man shall subscribe one pound annually in advance, and if taken in hand at once, we might obtain a corporation during the next session of Parliament. The amount placed annually in government securities at four per cent. would give in a handsome income at the end of the first year, out of which we could help the most needy. At the end of four years we would have nearly one hundred thousand pounds in fund, and before the century is out we might have about seven hundred thousand pounds. We might receive gifts and legacies, and with a fund of half a million, I think we could keep our poor widows from want, and give our sons and daughters not only a good education, but give them a trifle to start them in the world. I have now set the ball in motion, and I hope the heads of the Faculty will keep it spinning round as long as there are doctors in Old England. Before the middle of the next century this fund might reach two millions, just look what a prospect the rising generation would have before them, and all from a simple pound a year from each. Trusting that this will not be thrown away,

I remain, dear sir,

Yours truly,

ALEX. LANE, M.D. R.N.

Clun, Salop, 14th Sept., 1871.

#### MARTYRDOM:

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A large number of soldiers wives annually treated, now and then interesting facts come to light, which when found are made a note of. About 15 per cent. are soldiers' daughters marrying for a home, too frequently at a very early age, for instance, 6 per cent. under seventeen; and, in addition to climate, poverty, and hardship, are sometimes shamefully banged about by drunken husbands. This very morning a patient stated, that in addition to one abortion and four dead born, she had also given birth to five living children, not one of whom survived. She generally had an epileptic seizure at quickening, and too often during pregnancy her drunken husband kicked her in the stomach. Neither a toper nor a water drinker, "but simply" taking my whack when feeling "disposed," it is rather hard to give up one's liquor because others cannot draw the line of moderation. "Preaching" without practice, however, being merely "Stiggins" all over, there's no help for it but to sign the pledge.

The soldiers living by muscular wear and tear no more require alcohol than women do, but many brain-workers cannot repair nerve-power waste without stimulants.

India is a pestilential place, but many forget to mention the number of "brandy pegs" daily taken, nor do the water drinkers allude to the quantity of animal food they get outside of. In this place, there were 311 teetotallers last year, we could well afford a few more.

Drink and its results meet one at every turn, a man loses all patience and sympathy—at the present time with quite enough wrong otherwise, a nurse, a careful attentive woman, is reported to have been drunk last night, and keeping company with a soldier widower.

As the habits of years cannot be suddenly changed in the full swing of work, the plan is to take a rest and gradually drop all stimulants, although now quoting Rip Van Winkle, in a glass of sparkling, bubbling, iced champagne "Here's your health and your families may they live long and be happy." I hope to figure in the ranks of the water-drinkers, heart and soul supporting the "temperance" cause.

I am Sir, your obedient servant,

"SIMON THE CELLARER"

(not of the Privy Council).

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I take the liberty of requesting your opinion on the following matters?

An extensive farmer, between forty and fifty years of age, apparently in good health, was suddenly deprived of the

power of speech on the 27th inst. The following was the condition in which I found him: Unable to articulate a word except "No;" could not express by writing his ideas; was conscious; no other form of paralysis of motion or sensation; no difficulty in swallowing; nothing wrong with heart or pulse; constipation preceded the attack:

*Treatment.*—A blister on the head, croton oil, and an enema.

*Prognosis.*—Probably fatal.

A military surgeon saw him on the 28th inst. Ordered a blister to his head and a purgative powder. He said the attack would probably be of short duration, and that there was no danger. I visited the man on the 29th inst. He appeared just in the same state as on the occasion of my first visit, except that the tongue was very foul.

Will you kindly state your opinion on my prognosis in the next issue of your paper?

I remain, Sir, your obedient servant,

J. C.

P.S.—I should have stated that on the occasion of my second visit there was present a tendency to drowsiness, not due to any medicine taken.

[In a case of aphasia, as this evidently was, one must be guided in his prognosis by the probabilities of its cause. The only causes to be considered are: Firstly, Apoplectic extravasation into a portion of either anterior lobe of the brain (most probably the third frontal convolution of the left anterior lobe); and, secondly, embolism of one of the cerebral arteries (most probably the middle cerebral artery of the left side), causing red softening of that portion in which, according to M. Broca, the faculty of speech is localised.

Of these two the latter seems to us the more likely cause, inasmuch as our correspondent has given us no evidence of the occurrence of any of those general or local disturbances usually accompanying cerebral hæmorrhage; and we know, from the writings of Dr. Hughlings Jackson, that embolism of the left middle cerebral artery is a frequent cause of aphasia suddenly supervening, and not accompanied with paralysis of sensation or motion elsewhere.

Taking this view of the cause, and considering the occupation, age, and previous "apparently good health" of the patient, and the limited extent of the lesion as indicated by the entire absence of paralysis elsewhere, we would be rather inclined to prognose favourably, were it not that on the occasion of the third visit a certain "tendency to drowsiness, not due to any medicine taken," was present.

By this time, however, the case has probably so far progressed towards a final settlement of the question that further speculation would be idle.—*Ed. M. P. & C.*]

## Medical News.

**Apothecaries' Society of London.**—At a court of examiners, held on the 5th instant, the following gentlemen received the L.S.A. degree:—Messrs. Boughton Addy, of Southport; John Batley Bradbury, of Leeds; John Marshall, of Bolney; John Samuel Slater, of Bath; William Mallam Vores, of Great Yarmouth; and on the 27th ult., Mr. Shroffed Elam, of 40 Woburn square; at the same court Messrs. Handsford H. Clyma, of Guy's Hospital; and Samuel Welch, of the London Hospital, passed the primary professional examination.

**Dr. Beauperthuy.**—Dr. Gavin Milroy has recently, on the recommendation of the Royal College of Physicians, been despatched by the Colonial Government to the West Indies, in order to investigate the reality of the alleged cure of leprosy by a procedure, which Dr. Beauperthuy, a distinguished French physician, has for a considerable time adopted, the expenses of the mission being defrayed by the joint contributions of the Colonies interested in the matter. He was instructed first to visit Demerara, where Dr. Beauperthuy was then sedulously engaged in his important investigations, in order that he might have the opportunity of personal communication with him before proceeding through the other colonies on his tour of inspection; he had been received in the most cordial and friendly way by Dr. Beauperthuy, who impressed him with a feeling of great respect for his evident truthfulness and earnestness. The members of the medical profession at home and abroad

will regret to hear, that in a letter just received from Dr. Milroy, dated the 5th Sept., he expresses his great distress in having to announce that this indefatigable French physician, whom he had seen two days before in perfect health, had just suddenly died of apoplexy. Dr. Milroy was about to sail for Barbadoes.

**Hospital Sustentation by Working Men.**—£5,000 have been contributed in three years by the working men of Birmingham for the purpose of erecting an additional wing of the Queen's Hospital in that important town; to which, as we recently reported, her Majesty has contributed 100 guineas, making a special exception owing to this very fact.

**Sanitation in Whitechapel.**—In his report upon small-pox in the East of London, Dr. Liddle, the medical officer of health, gives a most deplorable account of the state of some of the closely confined courts. His description almost makes one fancy himself in some filthy fever district of Constantinople. He says:—In a place called Walton's court a child died from small-pox, and the body was kept for four days on the ground-floor room in which there were three other children suffering from the same disease. When the inspector visited the house there were two women in the room, who informed him that two persons lodged up stairs, and, from the faulty construction of the house, they had to pass through the room in which the dead body and the three small-pox patients were lying whenever they went out or returned home. Instances are plentiful were the bodies of persons who have died of small-pox in a public institution have been removed to rooms occupied as sleeping apartments by the relatives of the deceased, and from this cause small-pox has extended to the adjacent dwellings. Dr. Liddle complains that the sanitary authorities have no power to compel the removal of patients to an hospital, not even in cases where parents neglect their young children, and leave them under the charge of an elder child in a room accessible to all the other inmates of a house. Such is the utter disregard of proper precaution in his district, that Dr. Liddle declares "many persons having small-pox are often seen walking in the streets."

## Gleanings.

### A Rare Malformation in the Brain.

W. W. KEEN, M.D., Lecturer on Anatomy in the Philadelphia School of Anatomy, in demonstrating a brain recently to one of his dissecting classes, met with the following malformations, the first of which he believed to be very rare. In his own experience he had never met with it before, nor, so far as he had searched had he found any allusion to such an anomaly.

1st. The *fornix*, instead of being solid from side to side, consisted of two lateral halves, with a triangular space between them. This space was an inch and  $\frac{2}{3}$ ths long by  $\frac{2}{3}$ ths of an inch wide. It began just at the posterior border of the fornix, where the two posterior pillars were barely united, and reached nearly to the anterior pillar, where also slight union existed between the two halves. Through the opening the velum interpositum was seen.

2nd. The *fifth ventricle* was exceedingly large—the largest he had ever seen. It measured five-eighths of an inch wide, and an inch and three-eighths long. Neither this ventricle, nor the lateral ventricles were in any way diseased or distended with fluid. The dura mater corresponding to the right parietal bone was ossified in its outer layer. The anomaly noted in the fornix points doubtless to its normal origin and development by two lateral halves, whose separation is marked usually by the divergence of the anterior and posterior pillars only.—*Am. Jour. Med. Sciences.*

### Glycerine Lymph.

IN Prussia regular re-vaccination is very generally practised, the law making it obligatory on every person, and the authorities conscientiously watching over its performance. As a natural result cases of small-pox are very rare. It has, however, been objected, there as here, that lymph is scarce. To make the most of such lymph as there is, Government has tried its application mixed with glycerine, and the result has been so successful as to lead to a public recommendation of

the mixture to official vaccinating surgeons. The manner in which the glycerine lymph is prepared is thus described by the *Reichsanzeiger*:—The pustules of a healthy vaccinated person are opened with a needle, and the effluent matter carefully removed by means of a lancet, the same instrument being gently applied to assist the efflux. The lymph is then placed in the hollow of a watch-glass, and there mixed with twice its quantity of chemically pure glycerine and as much distilled water. The liquids are thoroughly well mixed with a paint-brush. The mixture may be preserved for use in capillary tubes or small medicine glasses. The lymph thus procured is considered equal in effect to pure lymph; care must, however, be taken to shake it before use. As the same quantity that now suffices for one is thus made to suffice for five, the discovery ought to be extremely useful in crowded cities.—*Boston Journal of Chemistry.*

### Iodine in Incontinence of Urine in Old People.

DR. SCHMIDT, of Munsterfeld, having witnessed useful effects from the exhibition of iodine in incontinence of urine resulting from paralysis, determined to try it in other cases. An old lady, aged eighty, who had always enjoyed good health and was very active for her years, was attacked, at the age of seventy-six, with dysentery, which very much weakened her. From this time the urine passed involuntarily, and for four years she suffered great misery in consequence; from her age her condition was looked upon as incurable. The author gave her one drop of tincture iodine every hour, and the following day she was able to hold her urine, and she continued the medicine (every two hours one drop) for a fortnight, and with complete success. The discontinuation of the medicine for some time led to a return of the symptoms, which disappeared, however, directly the medicine was resumed. It was continued, therefore, with occasional suspension, for two years, when she died from the effects of a blow.

Another case was an old man, aged seventy-four, who had suffered for six months from the same affection. He was ordered pills, containing each one-tenth of a grain of iodine. Immediate improvement followed; he died eighteen months later, from inflammation of the lungs.—*N. Y. Med. Journal.*

### Structure of the Glands of the Stomach.

PROF. HEIDENHAIM has been recently making investigations on the structure of the gastric and peptic glands. The mucous membrane of the stomach of dogs was hardened in alcohol, then stained with carmine or aniline blue, and examined with moderate microscopic powers. The glands are arranged singly like palisades, or in groups like the fingers of a glove, in close proximity to one another, and the orifice, neck, and body in each can be distinguished. The orifice in the grouped glands resembles the hard part of the glove, several glands opening into it, just as the fingers of the glove open into the wider hand part. This is lined by columnar epithelium. The neck, or narrower portion of each tube, is lined by roundish coloured cells. The body is lined by two kinds of cells, one external or marginal, round, and coloured; the other small, internal, and uncoloured, though their nuclei sometimes become tinted. The former, Prof. Heidenhaim calls investing cells (*belegzellen*), the smaller uncoloured ones he names chief cells (*hauptzellen*). The former probably represent the peptic cells of writers. The lumen of the glands is occupied by granular dark material. He describes with full details the action of the various re-agents upon the two above-mentioned forms of cells. He then gives the results of his researches on the glands during the digestion. They increase in size; the chief cells become swollen, and their contents are finely granular, showing that they have absorbed more than they have secreted. The investing cells are less altered. No division or multiplication of cells was observed.—*N. Y. Med. Journ.*, from *Schultz's Archiv. für Micros. Anatom. Bd. vi.*

### Raw Beef in the Vomiting of Pregnancy.

JAMES S. BAILEY, M.D., Albany, N.Y., writes:—In Oct. last I was called to see a female patient, aged nineteen, three months advanced in pregnancy. She stated she had been unable to retain any thing she had eaten during the last three days; that she had vomited more or less every day from the time of conception. She now was so much exhausted that she was unable to sit up.

A careful investigation of her case convinced me that the irritable condition of her stomach was entirely due to reflex action.

The raw beef was immediately suggested to my mind as likely to be retained, as I had several times previously employed it successfully in similar cases. I ordered my patient to take teaspoonful doses of raw beef, chopped fine, at intervals of three hours, with a little Cayenne pepper and salt sprinkled upon it.

At first the idea of eating raw meat was quite repulsive, but upon tasting it it was not found to be so disagreeable.

After the second teaspoonful was taken the vomiting ceased, and during the day the nausea disappeared.

My patient not only acquired a taste for this food, but rapidly improved in flesh and appearance, without a recurrence of this troublesome symptom.

#### A Remedy for Hæmoptysis.

DR. HOLDEN, of Newark, N. J., thus describes a method of treating Hæmoptysis, which has been successful in his practice:—

"I would like to call the attention of the Profession to a method of treatment of hæmoptysis, which, while most simple and efficacious, I have not seen described by any, viz., the throwing of the atomised vapour of a saturated solution of gallic acid directly into the mouth and throat. I have repeatedly found the most gratifying success follow at once, even in cases of profuse hæmorrhage. Unlike other styptics thus administered, it quiets the spasmodic cough, which seems the direct result of the presence of the blood, requires but a moment to prepare, and, aside from its efficacy, it inspires immediately the confidence of the patient. For about two years I have adopted this method, and have been surprised that no similar experience has found its way into the medical journals. My habit has been to have an atomiser and bottle of gallic acid always at hand, and when summoned hastily, to mix the acid in a tumbler of cold water, and use even without waiting for the excess of acid to subside. It has proved successful in several cases where the blood was streaming from the mouth with every expiration."—*N. Y. Med. Record.*

#### Therapeutic Value of Chloride of Ammonium.

DR. WILLIAM CHOLMELEY states (*Transact. St. Andrews Med. Grad. Association*), that during the last fifteen years he has been in the habit of employing this medicine in cases in which he deemed it appropriate, and among them are: 1. Some forms of neuralgia of the fifth pair, especially those occurring in women beyond twenty years of age, whose strength has been over-strained by rapid child-bearing, prolonged suckling, anxiety, want, or overwork. In doses of fifteen to twenty grains, given three times a day, the pain which is usually of a dull, aching character and intermittent, is quickly relieved, and ferruginous tonics may then be prescribed. 2. In some cases of more genuine tic-douloureux, and in hemiplegia it is invaluable. 3. Nervous headache, such as occurs in some patients after any violent emotion or strain of the nervous system, is readily amenable to the same doses mingled with chloric ether. 4. It is serviceable also in cases of myalgia, such as affects those whose work requires long maintenance of one position. 5. In sciatica, given in the same doses, in every four or six hours. 6. In lumbago. 7. In the painful sequelæ of rheumatic fever, and states analogous to this affecting men who are overworked. 8. Dr. Cholmely considers it finally to have a powerful emmenagogue influence in cases of amenorrhœa occurring in delicate and nervous girls and women, especially when this has occurred after exposure to cold and wet. In such cases it may be advantageously combined with the perchloride of iron. It is also beneficial in cases of dysmenorrhœa occurring in highly nervous or rheumatic patients, and in the various ailments that accompany the change of life in women.—*American Practitioner.*

#### Corrective Influence of Bromide of Potassium over Opium.

DR. J. M. DA COSTA (*Amer. Jour. Med. Sciences*), speaks highly of the great benefit derived by using bromide of potassium before giving opium in those patients in whom the latter drug produces unpleasant after-effects. He gives several cases illustrative of its action, in this respect proving its great utility and happy results. The bromide does not destroy either the anodyne or the hypnotic effects of the opiate; on the contrary, it rather heightens both, and more particularly the latter. He thinks the bromide acts best when given some hours before the opium, and forty to sixty grains—generally forty grains—prove sufficient.

#### Diphtheritic Membranes.

THE *Medical Archives*, July, 1871, contains the following views of Dr. Letzerich, translated from the German by Dr. Pflaum, of Pittsburg, Pa.:

"Diphtheritic membranes, taken from a large number of children who suffered from diphtheritis faucium et laryngis, showed, upon examination, after having been slightly hardened in a solution of chromic acid, according to the different stages of inflammation, different stages of development of a fungus (*hygodesmus-fuscus?*) upon and within the mucous membrane. At first there are to be found, in the adhering mucus, roundish, strongly shining granules; later, yellowish or brownish ones. From these shoot out very thin and tender filaments, which often form a very dense cluster, and penetrate the epithelium in such a way that the spots where they penetrate most are visible on the cell membrane. With their increasing exuberance, the epithelia decay more and more, and these filaments, at first without form, are later plainly visible, penetrate the mucous tissue deeper and deeper, and convert its structure into a compact homogeneous 'amorphous' mass; from which is seen to project on its free edge a number of long thallus filaments, lined with roundish granules containing spores, which sometimes form large and close sods. The growth, maturity, and shedding of the spores go on steadily and rapidly, and can produce infection of the contiguous mucous membranes.

"The penetration of those little organisms into the epithelial tissue corresponds to the preliminary, so-called catarrhal stage, their growth into the depth of the mucous tissue, and their exuberance within, to the properly diphtheritic stage of the disease.

"The violent infectiousness of the sputa of diphtheritics, which follows from such a condition of the membranes, renders necessary a very careful destruction of everything expectorated with caustic alkalis. For local application, the author recommends energetic cauterizing of all the faucial part and, what is still better, the rubbing off of the infiltrated places of the mucous membrane with powdered alum, and for the larynx the inhalation of pulverized lime-water? internally, the use of liq. potass. carbon., and especially of ferr. sulph. (0.3-0.5 grm.: 105 grs.)"

#### The First Stage of Syphilis.

In the *Centralblatt, f. d. Med. Wissen.* of Feb. 11, Dr. Sigmund says that the first stage of syphilis embraces the time of the eruption on the skin and mucous membranes. The bearing of this truth he explains in two paragraphs: 1. It is not correct to say that in some cases the skin affection is wanting, and that further on forms of more developed syphilis appear without secondaries. 2. In about half of the cases of syphilis, the disease is completely at an end after the first stage is past. There is no such thing as latent syphilis; the dyscrasia is recognisable or does not exist. Clinical experience now shows us that the dyscrasia sometimes gets cured without any therapeutic remedy; and also that there is no existing treatment which can hinder the appearance of the first stage of the disease. He thinks, however, that internal remedies may prevent the appearance of the tertiary symptoms, or, at any rate, make them appear more rarely. He admits that this is denied by many persons, but his experience of many years makes him believe that he is correct in saying so. He uses mercurial ointment for some time in the eruptive period. The value of iodide of potassium, says Sigmund, consists in its antiphlogistic action on the lymphatic glands, in the case it thus gives to all pains, whether in the head, limbs, or in whatever part of the body they occur. During the use of this remedy for several months the appearances of the first stage of syphilis fade away, as indeed takes place when no internal remedy is made use of. Chlorate of potash is of no use in syphilis, says Sigmund, and chromate of potash also is worse than useless. The "decoctions" are useless also. And as syphilis is a chronic disease, let us not omit hygienic remedies.

#### Tænia Caused by the Use of Raw Beef.

PROF. JOSEPH LEIDY, in an important communication made to the Academy of Natural Sciences of Philadelphia (March 21, 1871), stated that, "Recently, one of our ablest and most respected practitioners of medicine submitted to my examina-

tion a tapeworm which had been discharged from a young man, after the use of the *Aspidium filix-mas*. The physician, in giving an account of the case, stated that he had previously treated the patient for another affection, in which raw beef sandwiches had been prescribed for food. After looking at the worm, I remarked that it appeared to be the *Tenia medioanellata*, a species which I had not before seen, and added that the patient had probably become infected from a larva swallowed with the raw-beef sandwiches. The specimen consisted of the greater part of the worm, broken into several pieces. Including some lost portions, it was estimated to have been upwards of thirty feet in length. Unfortunately, the head proved to be absent; but, so far as characters could be obtained from the specimen, in the form of the segments, position of the genital orifices, and the condition of the ovaries, it agreed with the description given of *T. medioanellata*, rather than with *T. solium*. From a want of acquaintance with the former, I did not feel entirely satisfied that the specimen actually belonged to that species.

"Subsequently, my friend brought to me the anterior part of the body, probably, of the same individual tapeworm. He observed that his patient continuing to complain, he had administered another dose of the male-fern, which was followed by the expulsion of the portion of the worm now presented. The head of the parasite was included, and it confirmed the view that it pertained to the *Tenia medioanellata*.

"The case serves as another caution against the use of raw flesh or food."—*Proceedings of the Academy of Natural Sciences of Phila.*, May 1871.

#### NOTICES TO CORRESPONDENTS.

Dr. C. B. Fox, Scarborough.—One of the numbers you require is out of print, and cannot be obtained at any price. You can refer to the file containing it, any time you may be passing our office.

THE QUACKS.—A Correspondent kindly draws our attention to an elaborate article in *The Builder*, entitled "Medical Quacks, their dupes and Newspaper Supporters." We are much pleased the respectable portion of our lay contemporaries, is becoming alive to the foul blot which rests upon journalism in this country, by the encouragement offered to these charlatans in their obscene and abominable work, by the insertion of advertisements. Our excellent contemporary says: "THE MEDICAL PRESS AND CIRCULAR, of Sept. 13th, again returns to the exposure adding another hideous example to the long list of blood-suckers, and their dupes, who are swelling the catalogue of criminality and seething corruption. THE MEDICAL PRESS deserves the commendation of the profession of which it is an exponent, and also the thanks of the general public, both in London and Dublin, for its courageous action." We thank our contemporary for its eulogy, but more particularly for the powerful article which contains it. We began our war against the quacks almost single-handed, and notwithstanding the abuse and threats of legal proceedings heaped upon us we continued, and shall go on from time to time

"We've dogged their track of slime,  
And we'll shake the Gaza pillars yet  
Of their godless-mammon shrine."

If, like the contemporary named, all having a claim to respectability would join us, the contagion would soon be stamped out. Much has been done, and many of these scoundrels have either been imprisoned, or left the country. Much still remains to be done, in which work we invite the hearty co-operation of all.

THE PROFESSION AND THE DAILY PAPERS.—A Correspondent draws our attention to the frequency with which certain medical men address the lay press upon professional subjects. He instances Dr. Marsden, whose letter, giving symptoms, treatment, and doses of medicines, appeared in *The Globe*, *Observer*, and other London journals last week. We will not give our correspondent's opinion, as it is very strongly expressed, and somewhat personal. Our own we need not give, it is already so well known to our readers.

VOX POPULI.—We are much obliged. After all, the observation is worthy of its source.

F. B.—The paper is in type, but unavoidably delayed.

J. A.—We believe Dr. Day's work was published some years ago.

OBSTETRICIENS.—The society has already begun its sittings.

WAGON-WAGON.—We hear that it is "a carriage indicator," a sort of telegraph to give directions to the coachman without putting your head out of window. A gentleman who has seen it, tells us it would be a capital means of communication between the surgery and any other room.

F. R. S.—The book is out of print.

THE NEW LETTER POSTAGE.—An important reduction came into force for Great Britain and Ireland on Thursday last, whereby the cost of sending letters through the post, is materially reduced. Henceforward the rate of postage on inland letters, will be one penny for 1oz., formerly 2d., three halfpence will take 2oz., hitherto 4d., and two pence 4oz. (until now 8d.), an additional halfpenny for every two ounces.

#### VACANCIES.

St. George's Dispensary, London, W. Physician Accoucheur. (See advt.)

Charing Cross Hospital. Assistant Physician. Honorary. Margaret street Infirmary for Consumption. Visiting Physician. Hackney Union. Two Medical Officers. District No. 6, £80 per annum, No. 8, £80. Extra fees attached to both appointments. County Hospital, Guildford. House-Surgeon. Salary £75, with board.

Weymouth Union. Medical Officer. Salary £45, with extra fees.

York County Hospital, House-Surgeon. Salary £100, with board.

Dorchester Union. Medical Officer for Union and Workhouse. Salary 60 Guineas.

Corwall County Lunatic Asylum. Assistant Medical Officer. Salary £80.

Devon County Lunatic Asylum. Assistant Medical Officer. Salary £120.

Nottingham General Hospital. House-Surgeon. Salary £80, with board.

Nottingham General Hospital. Resident Surgeon Apothecary. Salary £150, with board.

Liverpool Northern Hospital. House-Surgeon. Salary £100, with board.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.  
Sugar Formation in the Liver. By J. C. Dalton, M.D., New York.  
Clinical Society's Transactions, Vol. IV. London: Longmans.  
Notes on Lying-in Institutions. By Florence Nightingale. London: Longmans.

Notes on Comparative Anatomy. By W. M. Ord, M.B. London: Churchill.

How to Arrest the Spread of Small-pox. By John Day, M.D., Geelong.

The Science and Practice of Surgery, pp. 1,255. By Frederick J. Gant, F.R.C.S. London: J. and A. Churchill.

The Family Medical Guide. By G. Fullerton, C.M., M.D. London: Chapman and Hall.

Nature; Allgemeine Wiener Medizinische Zeitung; Medical Free Press; Lyon Medical; Food Journal; The Practitioner; Le Mouvement Medical; The Australian Medical Gazette.

#### THE LONDON MEDICAL SOCIETIES.

HUNTERIAN SOCIETY, Wednesday, Oct. 11.—7½ P.M. Council Meeting.—8 P.M. Introductory Address by the President, and a paper by Dr. Dalry.

CLINICAL SOCIETY OF LONDON.—Friday, Oct. 13, 8½ P.M. Dr. Christian Bäumler, "On Cases of Partial and General Idiopathic Pericarditis."

—Dr. Anstie: "On a Case of Anæsthetic Lepra."—Mr. Nunn, "On a Case of Scrofulo-Dermia treated by Woodhall Water."—Mr. Geo. Lawson, "On the Treatment of a Case of Large Melanotic Tumour of the Eye, extending into the Orbit."

QUEKETT MICROSCOPICAL CLUB.—8 P.M.  
MEDICAL SOCIETY.—Monday, Oct. 16, 8 P.M. First meeting of the Session. A paper will be read by Mr. Gray. "On Crural Venosity."

## Marriages.

BEAVAN—MARKHAM.—On the 27th ult., at Riverhead, James Beavan, F.R.C.S.E., of Hereford, to Elizabeth Ward Markham, daughter of the late T. Markham, Esq.

EVANS—FENNELL.—On the 19th ult., at Smethwick Staffs, John Evans, M.R.C.S., of Cardiff, to Eliza, widow of the late Dr. Fennell, of Cardiff.

HENNESSY—HOWARD.—On the 27th ult., at Brighton, M. V. Hennessy, M.D., to Emily, eldest daughter of the late Captain Howard.

WHITE—BESLEY.—On the 5th inst., at Kingston-on-Thames, H. J. White, Esq., to Mary, daughter of the late Francis Besley, M.R.C.S.

## Deaths.

BUTLER.—On the 30th ult., C. Butler, F.R.C.S., of Brentwood, aged 82.

BUSHELL.—On the 5th inst., at 117 Crawford street, London, W. T. Bushell, M.R.C.S., aged 74.

DOCKFRAY.—On the 25th ult., Robert Dockray, L.R.C.S.I., of Kiltegan, Co. Wicklow, aged 47.

PANTON.—On the 26th ult., Geo. Panton, M.R.C.S., of Dorchester, aged 55.

YOUNG.—On the 1st inst., at Southend, A. K. Young, M.D., aged 69.

#### APPOINTMENTS.

CLARK, ANDREW, M.R.C.S., Assistant Surgeon to the Middlesex Hospital.

FITZ, S. W., L.R.C.P.L., House-Surgeon to the Dover Hospital.

FOX, J. C., M.B., C.M., Assistant Medical Officer at the Staffordshire Lunatic Asylum, Burnwood.

HEYGATE, W. H., M.R.C.S., Medical Officer for the Towcester District and the Workhouse of the Towcester Union, Northampton.

JOHNSTON, W., M.D., L.R.C.S. Ed., R.N., Medical Officer for the Southsea District of the Portsea Island Union.

LOWSON, G., F.R.C.S., extra Surgeon to the Middlesex Hospital.

LOW, R. B., M.D., Medical Officer for the Messingham District of the Granford Brig Union, Lincolnshire.

MORISON, B. P., L.R.C.P. Ed., House-Surgeon to the Hereford Infirmary.

PINDER, G. H., M.R.C.S., a Physician's Assistant at the Royal Infirmary, Manchester.

RIDLEY, J., L.K.Q.C.P.I., Medical Officer for District No. 2 of the Parish of Liverpool.

ROWORTH, A. T., Medical Officer for the Grays District, Orsett Union.

TESSIER, W. H. C., M.D., Medical Officer for the Halden District of the Tonderden Union, vice L. R. H. Rouse, M.R.C.S.E., resigned.

TIBBETS, E. W., M.B., Surgeon to the Bristol Police.

THOMSON, G., M.B., C.M., Medical Officer to the Parochial Board of the United Parishes of Cranie and Braemar.

WILSON, Dr. H. S., Demonstrator of Anatomy in the University of Cambridge.

ARMY MEDICAL DEPARTMENT.—The two under-mentioned officers having completed twenty years' full-pay service, to be Staff Surgeons Major, under Article 342 of the Royal Warrant of 27th December, 1870:—

Staff Surgeons: H. T. Reade, V.C., G. P. M. Woolv and, M.B.

Assistant Surgeon C. H. Browne, to be Staff Surgeon, vice W. M. Gibant, placed on temporary half-pay.

To be Staff Assistant Surgeons: J. G. Thornley, M.D., from half-pay, vice C. Backhouse, resigned; H. T. Brown, M.D., from 59th Foot, vice H. Bradford, appointed to the 59th Foot.

### ST. GEORGE, HANOVER SQUARE, DISPENSARY,

59 Mount street, Grosvenor square.

The office of PHYSICIAN-ACCOCHEUR having become vacant, gentlemen desirous of offering themselves as candidates for the above Appointment, being Members or Fellows of the Royal College of Physicians of London, are requested to send in their applications, accompanied with testimonials, to the Honorary Secretary, on or before the 30th day of October, and to attend the meeting of the Managing Committee on Tuesday, 31st of October, at 4.30 p.m.

T. ST. L. ALCOCK (Lt. Colonel), Honorary Secretary.  
CHARLES TURNER, Secretary.

### COKESTOWN HOUSE, INSTITUTED FOR

### THE MEDICAL TREATMENT OF THE INSANE OF BOTH SEXES.

This highly respectable Man-ion in no respect resembles, either internally or externally, what is usually known as an Asylum.

The Demesne, Conservatories, Graperies, and Grounds are unusually extensive, and in good condition.

There are Billiard Tables for both sexes, with indoor and outdoor amusements, including Vehicles.

Cokestown House is within three miles of Carriek-on-Suir Station, with a like distance from Fiddown, both on the Waterford and Limerick Lines, and in connection with the G. S. & W. and Kilkenny Lines.

For terms, and Form of Admission, apply to the Resident Physician.

JOHN PEPPARD, M.D., &c.  
Cokestown House, Piltown, co. Kilkenny.

### PURE AERATED WATERS.

### ELLIS'S

### RUTHIN WATERS,

Soda, Potass, Seltzer, Lemonade,  
Lithia, and for GOUT, Lithia,  
and Potass.

CORKS BRANDED "R. ELLIS & SON, RUTHIN," and every label bears their trade mark. Sold everywhere, and Wholesale of H. ELLIS & SON, Ruthin, North Wales. London Agents:—W. BERT & SONS, Henrietta street, Cavendish square.

### THE ADELAIDE HOSPITAL, PETER STREET, DUBLIN.

Physicians—Henry H. Head, M.D., M.R.I.A., Fellow of the College of Physicians, James Little, M.D., M.R.I.A., Fellow of the College of Physicians, Lecturer on the Practice of Medicine in the Ledwich School of Medicine.

Surgeons—Albert J. Walsh, M.D., President Royal College of Surgeons, John K. Barton, M.D., Fellow Royal College of Surgeons, Lecturer on Surgery in the Ledwich School of Medicine, Benjamin Wills Richardson, Fellow and Member of the Court of Examiners, Royal College of Surgeons.

Obstetric Physician—Lombé Atthill, M.D., Fellow and Examiner in Midwifery, College of Physicians.

Ophthalmic Surgeon—H. Rosborough Swanzy, M.B., L.R.C.S.I., Faculty Assistant at Professor von Graefe's Ophthalmic Hospital, Berlin.

Assistant-Physician—Walter G. Smith, M.D., Fellow and Censor College of Physicians, Senior Demonstrator in the University School.

Assistant-Surgeon—Montgomery A. Ward, M.B., M.Ch., L.R.C.S.I., Demonstrator of Anatomy, Ledwich School of Medicine, Examined Medical Scholar, T.C.D.

The central position of this Hospital renders it peculiarly convenient to gentlemen attending Lectures at the University, College of Surgeons, or Ledwich School.

The arrangements for Clinical Teaching have been made as complete as possible, and are such as not to interfere with attendance at the Medical Schools.

There are Fever Wards apart from the Hospital, and two Wards for Infants and Children.

Special hours are devoted to Clinical Instruction in the Diseases peculiar to Women, the Diseases of the Eye, and Cutaneous Diseases, and Students are individually instructed in the Use of the Stethoscope, Ophthalmoscope, Laryngoscope, and Microscope.

Two Resident Pupils are selected half-yearly.

Prize Examinations are held at the termination of the Session.

Further particulars can be obtained from Dr. Atthill, 11 Upper Merion street, or any other Member of the Medical Staff.

### The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

Established 1848.

### PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY LL.D. M.R.C.S., F.L.S., &c., (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays, from 11 till 2.

PRACTICES AND PARTNERSHIPS NOW OPEN for negotiation (in addition to those advertised in Dr. Langley's List, (which is sent post free on application).

Y 314. In the suburb of a large SEAPORT TOWN, a first-class Family PRACTICE, average income for last three years, £1,000. No dispensing; no assistant required; Midwifery fees from £1 1s. to £5 5s.; Visiting fees from 5s. to 10s. 6d. Six months' introduction would be given. The highest references afforded, and the fullest opportunities for investigation. Premium £1,250, part of which may be left on security.

Y 313. Partnerships in a first-class Country PRACTICE, in a WESTERN COUNTY. The income was formerly £900 a year, but has declined in consequence of the advancing age of the incumbent; who, however, retains the best part of the connection, returning fully £600 a year. The Practice is capable of almost unlimited increase, as the district is populous, and there is no opposition within four miles. Two horses and one carriage are used. Appointments yield £110. A suitable gentleman would be admitted upon easy terms, but must be able to command £500.

Y 312. High-class Non-dispensing PRACTICE with Partnership introduction. The average receipts have been about £1,000 a year, but have increased largely during last year. The patients include the aristocracy of the district. Midwifery fee, £5 5s. to £10 10s. Nearly the whole Practice lies within a mile radius. Visits, 5s. and 7s. 6d. The incumbent holds two government appointments, which yield about £100 a year. The residence is one of the best in the locality, in a charming situation, commanding a view of the sea and parts of the South Coast; being the Vendor's freehold, it can be purchased, or rented, or a smaller house adjoining could be occupied by the partner during the introduction. The successor must be well-qualified and accustomed to good society.

Y 311. First-class PRACTICE in a large MIDLAND TOWN. The annual income for many years has been upwards of £1,000. Patients of the very best class. All appointments have been declined. Midwifery fees £1 1s. to £5 5s. and upwards. Twelve months' introduction will be given. The town contains upwards of 50,000 inhabitants, and is rapidly increasing. Premium £1,000, of which £500 must be paid in cash, and £500 at the end of the introduction. The incumbent being well known in the profession can give the highest guarantees of good faith.

Y 310. Death vacancy in a fashionable Watering Place. Actual annual receipts have been £1,250. Patients of the very best class, a list of whom is in the hands of the agent. Owing to peculiar circumstances, a good introduction can be given. The residence is large and well-situate. The successor should be a gentleman not under thirty years of age, accustomed to practise amongst the wealthy classes.

Y 309. High-class Country PRACTICE, within thirty miles of London. Established forty years. Annual average income £800, and capable of great extension by an active gentleman. The population is about 3,000, and there are two other medical residents in the district. Patients of the very best class. All appointments have been declined. The residence is the best house in the town, containing sixteen rooms, with good gardens, orchard, stabling, &c. The whole held at a moderate rent. Two horses have been used in the Practice. Books are open to the fullest investigation, and an efficient introduction will be given.

## Original Communications.

### ON SOME FACTS CONNECTED WITH THE COLOURING-MATTER OF APHIDES.

By H. C. SORBY, F.R.S., &c.

I HAVE lately been occupied in studying the colouring-matter of insects, and find that several dark coloured species of aphides contain a substance of very considerable interest in connection with physiological chemistry. It is of still greater interest on account of its yielding several products having most unusual optical characters, which I shall not attempt to describe here in detail, but refer to my paper in the current number of the *Quarterly Journal of Microscopical Science*,\* confining myself now as much as possible to the more purely physiological part of the subject.

Since the publication of the valuable paper of Professor Stokes,† the important functions performed by the colouring-matter of the blood of vertebrate animals has been fully recognised, for the change in its spectrum so clearly proves, that it has the power of loosely combining with oxygen when exposed to the air, and parting with it to other substances in such a manner, as to meet the requirements of respiration. Ray Lankester has shown‡ that the green colouring-matter found in certain annelids behaves in a similar manner, and I have now found that the dark coloured species of aphides also contain a substance which I have named *Aphideine*, capable like both the above of being easily de-oxidised, and re-oxidised by exposure to the air. This compound may be conveniently obtained by boiling in a little water the fresh living red aphides found in downy patches on the bark of the apple tree. After filtering, the solution is of a crimson colour, made deeper by alkalis, but yellow by acids. In this respect it is similar to cochineal, but differs from it in

giving spectra without narrow absorption-bands, and in being easily de-oxidised. On adding to the solution a little ammonia and some of the double tartrate of potash and soda to prevent the precipitation of oxide of iron, the addition of a little of the double sulphate of the protoxide of iron and ammonia immediately removes the crimson colour, and makes the solution nearly colourless. On exposure to the air, it rapidly turns red from the surface downwards, and may in a similar manner be de-oxidised and re-oxidised over and over again. It cannot be thus de-oxidised when the solution is acid and only partially when neutral, as obtained from the living insects. I have made a number of experiments in order to determine whether it occurs in the insects themselves. When crushed under the microscope, the coloured liquid obtained from them appears to turn more crimson when first exposed to the air, but it is extremely difficult to decide the question, because the crimson colour is rapidly lost by the change of the aphideine into an orange-coloured substance. At all events, however, there seems every reason to believe that aphideine like hemoglobin and Lankester's chlorocruorin, may serve to convey loosely combined oxygen from the respiratory organs to other parts of the body. Probably other similar substances may exist, and possibly some may be colourless, so that their characteristics could not be ascertained by the spectrum method.

Another interesting fact connected with this substance is, that in some cases it passes with extraordinary rapidity into compounds of entirely different characters, having very unusual optical properties. The original aphideine is soluble in water, but not in bisulphide of carbon. It is therefore, in this respect, analogous to the colouring-matter of the blood of vertebrate animals, and quite unlike the colouring-matter of fats and oils. These are insoluble in water, but readily dissolved by bisulphide of carbon. On exposing a solution of aphideine to the air, it changes successively into three substances, which behave with solvents, not like the original, as the colouring-matter of blood, but as the colouring-matter of fats, and are themselves of waxy or fatty consistence. These are all remarkable for being very fluorescent. Two are yellow, and the transmitted light gives spectra, with well-marked ab-

\* New Series, xi., 352-361.

† Proceedings of the Royal Society, xiii., 357.

‡ *Journal of Anatomy and Physiology*, iv., 119.

sorption bands. I have named them *Aphidiluteine* and *Aphidiluteoleine*. The final product is red, and I have therefore called it *Aphidivirrhodeine*. Its spectrum contains five remarkable absorption-bands. The light of fluorescence is orange, and its spectrum shows a bright, well-defined orange band, so narrow that it is only about 1-50th part of the entire spectrum of day-light; and thus the fluorescence is almost monochromatic. The production of these substances by the action of the air on aphideine appears to me very interesting in connexion with the formation of fat and wax, and the rapidity of the change is in some cases very striking. When the living insects are crushed at once in ether, and the solution agitated with water, this sinks to the bottom, holding all the aphideine in solution, and leaves the ether of pale yellow colour. Evaporating this to dryness, a small quantity of yellow, fatty matter is obtained, which, when dissolved in bisulphide of carbon, gives a spectrum with no well-marked absorption-bands, like the fatty or waxy constituent of other insects. If, however, similar living aphides are crushed in a test tube, exposed to the air for a few minutes, and then treated with ether, on agitating it with water the aqueous solution subsides almost colourless, whilst the ether is coloured a deep yellow with the altered product aphidiluteine. When evaporated to dryness, it leaves a waxy substance, soluble in bisulphide of carbon, which gives a spectrum with two well-marked absorption bands in the blue. This very striking change takes place so rapidly that for some time I thought that the yellow, waxy substance was a normal constituent of the living insects, whereas there can be no doubt that it is formed from the aphideine by exposure to the air. The rate of change varies much according to circumstances. When extracted from the living insects by means of boiling water, the solution is only partially altered in the course of a day, whereas, when extracted by crushing them in cold water, the alteration is almost complete after a few minutes. It thus appears as though the cold solution contained some (perhaps albuminous) substance, destroyed by boiling, which, by its speedy decomposition, induces the more rapid change in the aphideine. The same alteration takes place in dead insects, only not so quickly; but still, after having been killed by exposure to the vapour of bisulphide of carbon, and kept even for no longer a period than a quarter of an hour, the change is sufficiently great to lead anyone into serious error, who did not expect that any material amount of decomposition could occur in so short a time. No doubt, it is a somewhat unusual case; but yet it seems to point out the importance of always being on our guard, and using special care to ascertain whether any particular substance is really present in living animals, and not a product rapidly formed after death. In the case of aphides, circumstances are remarkably favourable for determining this point, but very often it might be extremely difficult, and yet of no less importance in connexion with physiological chemistry.

### ON MENINGITIS AS A CAUSE OF DEATH IN INFANTILE CHOLERAIC DIARRHŒA AND CHOLERA.\*

BY WILLIAM CURRAN, L.R.C.P. Ed., M.R.C.S., Lond., &c.,  
Army Medical Staff.

I AM almost ashamed to bring so trifling a subject under the notice of the society, and am only induced to do so now, in redemption of the pledge I was weak enough to give on the occasion of our last meeting, and, in order to restrict, any discussion that might take

\* Read before an association of brother officers which was organised by some enterprising members of both services at Peshawur in the early part of the year 1868, and which elicited some valuable information about water supply, the spread of cholera, and other questions of local interest during the period of its short and precarious existence. Though not improved by the time which has since elapsed, and in need mayhap of a little trimming, the writer prefers reproducing it word for word as

place to one topic only. The time at our command is at this season, necessarily limited, and it is I think advisable to devote as much of it as we can fairly spare to an exhaustive consideration of the principal question proposed for review. Dr. Clarke having kindly consented to favour us with an historical sketch of his experience, in respect of the outbreak of cholera that caused so much havoc here last year, it occurred to me, that some account of a collateral offshoot or issue of the same distressing visitation would not be out of place on an occasion like the present, and hence the heading noted above. Meningeal irritation as consequent on or associated with cholera in infants and young children is, as far as I know, almost the only phase or feature of this terrible malady that has not been thoroughly ventilated elsewhere, and by far abler pens than mine; but I may have exaggerated its importance or overlooked the fact of its more frequent occurrence, if so, I must bespeak the indulgence of the Society, and plead as some excuse for my ignorance, the drawbacks of my position, and the unvarying sameness and monotony of military practice. I have not devoted much attention to the periodical literature of medicine of late, indeed my mind has been running in a very different groove for some time back, and if I have over-rated the value, or set more account by the presence of this condition than its interest or importance may appear to deserve, I regret the mistake and freely submit myself for correction.

Such being, in short, my own estimate of the subject, you will easily infer that it is not my intention to delay you long, or to discuss very minutely the pathology and symptoms of this complication. Brevity is the soul of wit, in the narration of clinical experience, as in the statement of criminal law, and I fully agree with Mr. Carlyle, when he says that "there is an endless merit in a man's knowing when to have done." The stupidest man if he will be brief in proportion, may fairly claim some hearing from us: he too, the stupidest man, has seen something, heard something, which is his own distinctly peculiar,—never seen or heard by any man in this world before. Let him tell us that, and if it were possible *nothing* more than that, "he brief in proportion shall be welcome." This is a very suggestive sentence, but I fear I shall fall far short of its requirements, as I can scarcely claim in the present instance to have heard or seen anything that I can call my own *distinctly peculiar*, and I am unwilling to trouble you with petty details or indulge myself in wild hypothesis or untenable theory. Crude conjecture or dreamy speculation is not likely to find favour from such an audience as that I have the honour to address, and I am warned by the same philosophic writer, that "in all matters of business or science, in all expositions of fact or argument, clearness and ready comprehensibility are a great, often an indispensable object." Keeping the necessity for these in view, I will endeavour to steer a middle course and reconcile brevity in statement, with clearness in description and accuracy in the enunciation of fact. By this means, I hope to be able to avoid extremes, which are we are told always dangerous—and escape at the same time that obscurity which too much condensation sometimes entails."

"Brevis esse laboro, obscurus fio."

My attention was first directed to this complication by noticing that during the cholera epidemic which visited England in 1853, several children that had survived the more urgent symptoms and shaken off all apparent liability to a fresh attack, either suddenly succumbed to a return of their old malady, or pined away gradually under the influence of a spell, which few interpreted alike, and none appeared able to control. The symptoms in either case were aggravated by the addition of head sympathy,

it stood in the original, to recasting it *de novo*, as he believes it will be more acceptable to his readers in its primitive dress, than it would be in a newer and more ornate costume, and he is willing to hope that the conditions under which it was written, and which it is needless to relate but easy to conjecture, will be remembered in its favour, and allowed to atone for its many pathological and others shortcomings. He did his best under the circumstances, and more than that no man can do.

and the few hurried *post-mortems* I was allowed to witness, clearly showed that such was the case, and that the brain or its membranes, played a more active part in them, than that of a mere accessory before the fact. I subsequently noticed a tendency in the same direction among some children, the subjects of a spring diarrhoea or English cholera I had under my care while discharging vicariously the duties of medical officer to one of the poorest parishes in Westminster, and having observed for the third time and under very different atmospheric agency, that certain children of my regiment, that were attacked in camp near Cawnpore, during the epidemic of 1864, went out with equally painful evidence of brain derangement I made a covenant with myself, that, should another similar opportunity offer, I would turn it to better account than I had been able or was allowed to do on either of the former occasions. The opportunity occurred sooner than I had anticipated or could desire, for it was the means of spoiling my well-earned leave to Cashmere, in May 1867, and the cause of my recal after a weary march of 170 miles or more within three days of my arrival in its ancient capital. Soon after reaching head-quarters at Rawul Pindee, I was ordered to take up my residence on a bleak hill side, near Tréte,\* and afford medical aid to the women and children who were being sent up from this garrison to the family camp at Clifdenn, near Murree. After remaining there for about a fortnight or three weeks, a sudden outbreak of cholera, which carried off in a few hours a woman and three children of my regiment, necessitated the removal of the other families into camp, and as it was in contemplation to pass them on to Nundkote, I was ordered to hold fast at Tréte till further orders. It was here that I gained the additional scrap of information referred to above, and as this does not amount to much at the best, I will after a short but almost unavoidable digression, proceed to deal with it as summarily as I can.

Three cases in point will answer the purpose I have in view, and the few searching words devoted to the description of each, will render any very minute prefatory narration of symptoms unnecessary. There is no science to which the saying "ex uno disce omnes" more appropriately applies than to that of medicine, and a little judicious pruning and compression will, in a climate like this, invest technical details with an interest and often ensure for them an attention which no amount of embellishment or padding would otherwise command. It is well-known that the delicate nervous organisation of young children, renders them peculiarly liable to the effects of eccentric irritation, and convulsive disorder is so common a consequence of gastro-intestinal disturbance in early life, as to be no longer a fit subject for scientific speculation or comment.† This is not, however, the complication that I allude to here, and infantile convulsion is no longer held to be necessarily pathognomonic of disease of the brain. The form of cerebral complication that I now contemplate, has a more dangerous origin and a graver significance, and the principal object of this little paper is to show that acute or subacute—and I believe this to be the prevailing type—inflammation of the meninges leading to effusion or perhaps false membrane is a more frequent cause of death in children, who

have suffered from exhausting discharges during epidemic seasons, or who labour under the influence of a choleraic cachexia, than we find recorded in books, or than is generally supposed.

The night of August the 2nd, 1867, at Nundkote, was one of the most stormy and boisterous that I have ever witnessed.\*

Rain poured down in torrents saturating the tents and flooding the encampments in all directions, frequent flashes of lightning, "cerebris micat ignibus aether," that wriggled for a moment in the troubled sky served but to make the darkness more visible, and the thunder reverberating through the neighbouring hills formed an unearthly combination of sound and fury that I have no wish to witness again. Frequently called up to minister to the requirements of my charge, I had ample opportunities of making acquaintance with the elemental strife that raged so furiously without, and of recalling some of the most touching staves of those old sea songs with which most of us are familiar through the sham or shipwrecked sailors that bawl them out during the winter months in country villages and wherever else skilled enquiry is not likely to be brought to bear on them. On the morning of the third, finding that some evil influence had been at work in the camp during the night, I made the following remark in the case book. "It is curious to note, but difficult to account for or define the agency by which five different previously healthy persons were attacked on the same night, and by a train of symptoms which are in the main very nearly identical, or at most only modified by peculiarities of age, constitution, and temperament." Dr. Clarke has just told us, that "a severe thunder-storm burst over the encampment of the pilgrims at Hurdwar, about three millions in number, on the night of the 11th of April, 1867, and cholera made its appearance in an epidemic form on the afternoon of the 12th,† and I read in a number of the *Delhi Gazette* for July of the same year, a graphic account of the wave of destruction which swept so disastrously like "a hurricane eclipse of the sun" over this station last year, and which so fully confirms his description that I willingly reproduce it here. "On Monday morning 20th inst., all was well, and yet before nightfall as if the Angel of Death had blasted with evil our fair valley, no less than eight Europeans had been stricken down dead with cholera. Like an avalanche it came down upon us. Six men of the 42nd Highlanders, two men of the Artillery, and three or four native soldiers, had fallen victims in a few hours. The blow was sudden and fierce, and it smote us all with sadness and sorrow." I believe that a similarly sudden and violent atmospheric change, preceded that terrible outbreak of cholera at Mean Meer, in 1861, which carried off according to a paragraph in the

\* This was the only time in my life that I felt the effects of "funk," and the latter was brought about in this wise: Returning to the leaky hovel in which I resided for the fifth or sixth time during the night, or rather as the light of day was feebly struggling through the murky air, drenched to the skin, and troubled with diarrhoea and griping, I feared that I was in for an attack of cholera, and having no faith in the power of physic in that disorder, straightway gave myself up for lost. It wasn't the fear of death or its consequences that frightened me, but the sense of my helplessness at the time, and the feeling that I was alone on a bleak hill-side far away from all who cared for me. To these were added the natural reluctance of a person of my age to part with life, at a time when its attractions were greatest, and go down, "unwept, unhonoured, and unsung," save, perhaps, by the passing wail of one of my poor countrywomen to a nameless grave amid the mountains, to which none of my kindred would ever have access. These reflections, small as they may appear at this distance of time and place, had then a great weight with me—all the sadder memories of my life came suddenly upon me, and as I lay down on my dripping couch, I cursed the hour I accepted a commission. Would to God it were the only time I had reason to regret that fatal step!

† Dr. Clarke subsequently informed me that "the camp was supposed to have been free from the disease before the 11th;" and he added, "I am induced to think that a cycle of choleraic air struck the pilgrims—not that the seeds of the disease lying dormant in the ground of the encampment were vitalized by the rain." This belief accords so much with my own experience of visitations of cholera elsewhere that I readily endorse it; and simultaneous outbreaks of that disease at such distant intervals, and under circumstances so varied as those referred to above, seem to me to bear more support to the theory of its propagation advanced by Dr. Bryden than to that of Pettenkofer, Murray, MacNamara, Parkes, or other writers of my acquaintance.

\* A small but picturesque village and halting-place between Rawul Pindee and Murree, where there is a good hotel and staging bungalow, and where the writer heard the monotonous "wood note wild" of the cuckoo for the first time in India. Nundkote, situated on the brow of an adjacent hill, is the (now abandoned) resting camp here referred to.

† Trousseau's explanation of this now well-ascertained physiological fact is worth reproducing in full for its own sake. Enumerating the causes of infantile convulsions, he says, *inter alia*: "Profuse diarrhoea persisting for a long time acts in the same way, that is, in producing convulsions in children. This need not surprise, if this great physiological law be kept in mind—namely, that in proportion as the nutritive and vegetative functions are feeble and languishing, nervous phenomena are mobile, exalted, and irregular, a law which has been admirably enunciated in this simple observation of Hippocrates—*sanguis moderat nervorum*, if it be especially remembered that the dependence of the nervous system on the blood and the nutritive functions is most strikingly marked in children.—Lectures on Clinical Medicine, "Sydenham Society's Transactions," vol. i, p. 343.

*Lahore Chronicle* for September 14th, of the same year, between the 6th of August and the 13th September, the frightful number of 534 European souls, and reading lately an article entitled "A City of the Plague" in *Blackwood's Magazine* for October 1867, in which it was said, that on the morning of the fatal outbreak at Albano, "the air grew dark, a wild wind rose and chilled the thinly-clad inhabitants to the bone, it came upon them without warning, like a sudden doom, and drove the village folks indoors, to hug their winter cloaks to them and seek warm clothing." I was forcibly struck with the resemblance the visitation bore to my own, and I am now more satisfied than I was before that cholera is carried along on the wings of the wind, rather than by water or other telluric or local agency. The writer adds: "That day there were seventy deaths from cholera in Albano, and all the wild incidents of a plague-stricken city were brought into immediate life in the little town, which but a day before had been so pleasant and cheerful." Many other instances in point could be quoted here, but time will not allow of my going farther into the subject at present, and requesting the attention of the Society to the point, I will now proceed at once to dispose of the issue in hand.

(To be continued.)

## THE SITTING POSTURE IN PROLONGED CATHETERISM.

BY R. HANSLIP SERS, M.R.C.S.

IN cases of stricture, organic or otherwise, considerable time and patience are required both by the operator and the operated. Thus, a working-man after a heavy day's work will beg to be seated—he dreads the fatigue—the faintness and the muscular trembling produced by leaning during a length of time against a wall. Then one may have a corpulent patient suffering from hemiplegia accompanied by stricture, or an elderly patient with enlarged prostate. It may be inconvenient in these cases from a local circumstance to lie upon a couch. The time occupied by the operation is commonly considerable, hence the temperature of the room, especially in the winter, is of importance. Under these conditions I permit the patient to sit upon a chair in a semi-recumbent posture, with the nates close to the edge and the knees widely divergent. This admits of any requisite manipulative process. In stricture, I have faith in prolonged sittings, at least in otherwise healthy country persons in the prime of life, to enable one *leisurely* to exert that steady pressure—gentle yet efficient—so familiar to the expert. The sitting posture answers admirably, and is superior to the upright, and I think also to the flat position. I am uninformed whether or not this method is advocated by either home or foreign surgeons.

## THE SEWAGE QUESTION.

### SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XXVII.

### AGRICULTURAL VALUE OF SEWAGE.

(Continued.)

In illustration of the great difference of opinion among theoretical and practical men, as to the quantity of sewage that ought to be applied to a given area of land, we may quote the remarks of Mr. Lawes, on the evidence given before the Select Committee of the House of Commons, "On Sewage of Town." "One witness who had been en-

gaged for years in the application of sewage, and whose evidence is said in the 'Analysis of Evidence,' to be 'entitled to great weight,' gave it as his opinion that, 300 tons of sewage per acre would accomplish the same results as the 10,000 tons which he had, in point of fact, applied. Another witness, just returned from a visit of inspection of the sewage meadows at Edinburgh and Rugby, considered the inferiority of the produce at Rugby, to be due to the much smaller quantity of sewage there applied, the amount ranging from 3,000 to 9,000 tons per acre; whilst, in the case of the Edinburgh meadows to which he referred, it was estimated by the same witness at 10,000 to 12,000 tons per acre, and to be as high as 30,000 to 40,000 tons on some of the meadows in that locality." There are authorities in fact who declare that as little as 100 tons of sewage per acre per annum is sufficient for agricultural purpose. Mr. George Shepperd, a sewage engineer of some notoriety has expressed this opinion, and so also has Mr. Mechi, the champion of sewage farming, whose mode of reasoning is somewhat as follows:—A human being is equal to a sheep in manurial value. Now in England, according to statistics, the land only receives the manurial results of two sheep per acre per annum from all the farm animals in the country, reckoning bullocks, horses, pigs, &c., in their proper equivalent proportions as sheep. Therefore, says Mr. Mechi, the manure of two persons is enough, as a normal dressing, for ever acre of land; and this is just 100 tons of ordinary sewage, when the water supply or degree of dilution is at the rate of thirty gallons per head daily. But experience has shown even under Mr. Mechi's supervision, that twice this amount is insufficient. The experiments to which we allude were made at Rugby some years ago by Mr. James Archibald Campbell, who brought with him from Edinburgh, as we have before said, the largest notions of the agricultural value of sewage, and being desirous of realising at Rugby the sewage wonders of Edinburgh, he became an enthusiastic sewage farmer, taking about 190 acres of land from Mr. Walker, and agreeing to pay him a guinea an acre for five dressings of sewage applied to the land between the months of March and October. At the onset, says Mr. Campbell, a question arose as to what constituted a dressing, and it was left to Mr. Alderman Mechi to say how much it should be. That gentleman, after grave deliberation, decided that the quantity was to be 9,000 gallons, or 45,000 gallons per acre for the five dressings. This is almost exactly 200 tons an acre; but it was soon found to be insufficient; and year by year he went on reducing the area of land until he put the whole of the sewage, for which he paid £150 a year, on about twelve acres of land. In a pamphlet published by Mr. Campbell, in which he gives the results of his experience for eight years as a sewage farmer, he states "that he should expect a better paying return from fifty acres with 4,500 tons per acre per annum, than from 100 acres with 2,250 tons an acre." Mr. Mechi could hardly fail to profit by these results, and so he has since recommended that from 500 to 600 tons of sewage per acre should be applied to the land. He has even said that for green crops 1,000 tons might be used, and perhaps, in the case of London sewage as much as 2,000 tons an acre; although he cannot forget that his friend, Mr. Miles, of Bristol, produces excellent results with the sewage of thirty persons upon fourteen acres of land. Mr. Thomas Ellis, who was a candidate for the sewage of London, proposed that it should be distributed

at the rate of 500 tons an acre per annum, and his views were strongly advocated by Mr. Brady, the chairman of the Select Committee on Sewage. Reasoning in much the same way as Mr. Mechi, he said that "as good results were obtained from twenty tons of farm yard manure upon an acre of land, and as thirty tons of sewage were equal to at least one ton of rich manure, it was evident that 600 tons of sewage per acre were enough for all practical purposes." This is the produce of a dozen people, and is therefore an extravagant allowance when compared with the fancy farming of Mr. P. S. Miles, of Bristol.

Messrs. Hope and Napier, whose scheme for the utilisation of the northern sewage of London upon the Maplin Sands, and Dengie Flats, was accepted, with some modifications by the Metropolitan Board of Works, were of an opinion that 1,750 tons an acre are sufficient for profitable results; and very recently at the meeting of the British Medical Association at Plymouth, Mr. W. Hope read a paper "On Sewage Irrigation in connection with Public Health," wherein he stated that in most cases the sewage farms of this country were, as Dr. Letheby and Mr. Hawksley had described them, pestilential swamps; and this he attributed to the application of sewage in too large quantity, especially during the night when plants could not utilise it. He therefore recommended that sewage should be sparingly used—an acre of land being allotted to every twenty or thirty persons, as "it seemed exceedingly doubtful whether, having regard to the commercial side of the question, it would be practicable to utilise the sewage of more than twenty or thirty persons per acre over a term of years." This is at the rate of from 1,000 to 1,500 tons of sewage an acre per annum; and it is we believe the quantity used by Mr. Hope, upon the 121 acres of Breton's farm, near Romford, of which he is the lessee. A like opinion was entertained by Mr. Westwood, the farm Bailiff of the School farm at Annerley; for he said in his evidence before the Parliamentary Committee, that when more than 1,500 tons an acre was applied to the land (clay) it ran away into the drains, and fouled the stream. He found this to be the case with ground receiving from 8,000 to 9,000 tons an acre, even when it was cultivated with rye-grass. Baron Liebig also is of opinion that small dressings are more advantageous than large, because sewage ought not to sink deep and be lost. A soil, in fact, saturated with manure not only fails to increase the crop, but becomes, except in the case of roots, positively hurtful. Meadow land, he says, to yield four tons of hay per acre, or twelve tons of grass, would require 2,430 tons of sewage; and even then about two-thirds of the ammonia and one-third of the phosphoric acid are left unutilised—the potash only of the sewage being appropriated. On the other hand the Earl of Essex, who was the chairman of the commission appointed to inquire into the best mode of utilising the sewage of towns, and who rents the sewage of Watford, began by distributing 60,000 tons of sewage annually upon 210 acres of mixed arable and grass land which he had under-piped, but he found it was necessary to limit its application to a much smaller area, and almost exclusively to either permanent meadow or Italian rye-grass. He stated in fact in his evidence before the Committee of the House of Commons, that practically he had limited it to about ten acres of rye-grass, and thirty-five acres of meadow land—"I put," he said, "about 5,000 or 6,000 tons a year to each acre of Italian rye-grass, and 600 tons on each acre of meadow land—making between 60,000 and 70,000 tons of

which I calculated I got from the 4,000 inhabitants of Watford." This is the quantity which is used at Croydon, Bambury and Warwick. Dr. Voelcker is of opinion that from 2,000 to 4,000 tons an acre may be put upon better kinds of land, but that porous soils of a sandy nature will take from 8,000 to 10,000 tons per acre. "When," he says, "we apply a large mass, say 7,000 to 8,000 tons to a soil which is naturally porous and deep we incorporate with a large body of soil a considerable quantity of solid, real fertilising matter. By using such large doses upon grass crops grown upon a poor soil, these solid manuring matters which are disseminated through a large body of soil by capillary attraction, are brought within reach of the roots of the plant. The evaporation which takes place from the leaves of grass crops is very considerable; the moisture from a considerable depth is drawn up, and with it all the solid matters dissolved in it. Then we see a marked effect upon vegetation, which will explain in practical experience, why quantities of 300 to 400 tons an acre, even applied to grass lead to no practical result, whilst large quantities applied to the extent of 8,000 or 9,000 tons (and I am not sure that even larger quantities may not be used with advantage) produce a good result. That is a matter which is clearly determined by experiment; for I have nowhere seen such small quantities as 300 or 400 tons an acre produce any decided beneficial and remunerative effect." Professor Way has arrived at the same conclusion, for in speaking of the sewage of London, he said that "you could advantageously use the sewage of 3,000,000 people upon 30,000 acres of land, which would be the excreta of 100 people per acre, provided it was all grass land; but it would be advantageous to take a larger area, because the only way in which you can deal with it is by feeding it into milk, or into flesh, and you would have a very large quantity of manure produced by the cattle in addition to the sewage; consequently, you will have the means of returning an increased quantity of manure to the land." Mr. Lawes, after a careful consideration of the subject, decided to apply it experimentally at the rate of from 3,000 to 9,000 tons an acre upon the land at Rugby, and the results of his experiments were that less than 5,000 tons an acre were not sufficient for profitable returns. Mr. Robert Rawlinson, who once had the most extravagant notions of the value of sewage, has since learnt, and candidly admitted, that an acre of land is required for every 100 persons, which is at the rate of 5,000 tons of sewage per annum; and Mr. Bailey Denton, whose views of this subject are rather peculiar, is nevertheless of opinion that for actual working an acre is required for every 100 or 150 persons, according to the porosity of the soil—lighter soil taking the sewage more freely than heavy; but still he thinks that extra land is necessary on various reasons, and especially for alternate cropping, and for occasional rest of the land. He says, indeed, "that the excrement of five persons, worth thirty shillings per annum, is equal to as many loads of farm-yard manure, and will do for a rood of ground, worked with reference to cropping, and applied to half the land each year." This is at the rate of only twenty persons to an acre, or forty for the land actually in work. Even supposing that the excreta are applied in a concentrated form, Mr. Bailey Denton's views are very different from those of the late Sir Joseph Paxton, who said in his evidence before the Parliamentary Committee that he could put the sewage of 250 persons upon an acre, when it was not diluted with more than a tenth part of the water in

London sewage—whereas in the latter case it would require 30,000 acres for its appropriation. At Edinburgh, however, the sewage of about 80,000 persons is put upon 250 acres of sandy soil; and this is at the average rate of 16,000 tons an acre; although in practice it ranges from 10,000 to 40,000 tons an acre according to the requirements of the crop.

It comes, therefore, to this, that after an experience of nearly twenty years, in every variety of situation, season, and soil, with all the enthusiasm and diligence necessary for success, the so-called practical men are unable to declare definitively what quantity of sewage can be safely and profitably applied to a given area of land; for in active practice it ranges as we have seen from 100 tons an acre per annum to 40,000 tons; or, to put it in the form of acreage to the population, it ranges from two persons per acre to 800 persons. What further proof is necessary of the difficulties of the whole question, and of the uncertainty of the conditions upon which even a partial success is dependent? One thing, however, is conclusive, and that is the diametrically opposite conditions of sanitary and agricultural success, for while in the one case, a limited supply of sewage to the land is necessary, in the other it must, at certain times, be almost unlimited. To be safe in fact, as regards freedom from nuisance, the land must never receive more than from 1,000 to 1,500 tons of sewage per acre per annum; whereas for commercial profit it must never have less than 5,000 tons an acre; in the former case it represents a maximum of thirty persons to an acre, and in the latter a minimum of 100 persons.

Next, as regards the crop to which sewage irrigation is most suitable. Some are of opinion that it is applicable to every description of produce provided it is used at a proper time and in proper quantity, though others assert that it is only fit for grass crops and succulent roots; all however are agreed that it is most profitably applied to Italian rye-grass and to pasture land; and that it will in dry seasons augment the yield of hay if it be used at a proper time. The Earl of Essex began by distributing it over arable as well as grass land, but he ended by limiting it almost entirely to permanent meadow land and Italian rye-grass. The same was the case with Mr. Campbell at Rugby, although both of them think that sewage is good for roots in dry weather, and even for wheat at a proper time. Mr. Mechi says it is best not to apply it to the land immediately for wheat, but to a preceding root, grass, or clover crop, because if it is applied to wheat it causes it to be too luxuriant, and to full early. Mr. Congreve, of Rugby, is evidently of the same opinion, for he says it will increase the quantity of straw but not of corn; and he adds that although it will greatly promote the growth of grass, both natural and artificial upon poor land, it cannot be applied with good effect to roots, because it contains so much water that your land is in a state of sea if any quantity is upon it. Mr. Miller, of Edinburgh, has arrived at the like conclusion, for he found it made furrows and channels in arable land, and washed the roots of plants bare. It was in fact positively hurtful to wheat and he doubted if its immediate application was of any benefit to turnips. Dr. Voelker, Professor Way, and Mr. Lawes have expressed themselves to the same effect, and have condemned the use of sewage for arable land. "It may," says Dr. Voelker, "be fit for pasture land and for raising coarse green crops, but it is quite unfit for cereals

after the grassy state, because of its forming straw instead of grain, and checking the ripening process." It is even unsuited, in his opinion, for market produce, as it clogs the soil and kills the plant. Mr. Way also advocates the use of sewage upon grass land, because it is the only way in which you can deal with it, by feeding it into milk or flesh, and so getting a more manageable manure. While Mr. Lawes, in his article on the "Utilisation of Town Sewage," says that "it seemed impossible to account for the abandonment, at Watford and at Rugby, of the use of sewage to crops generally, and in comparatively small amounts per acre, after so large an outlay had been incurred entirely with a view to its application in these very ways, excepting on the supposition that the practice was not found to be profitable;" and in the combined report of these gentlemen on "The Sewage of Towns," they say, in general conclusion, that "where the most extensive trials of the application of sewage to corn crops have been made with a view to profit, namely, at Watford, Rugby, and Alnwick the practice has been abandoned, whilst neither at Edinburgh nor Croydon, where the best results have been obtained with grass, does the application to corn and other rotation crops constitute a part of the general system adopted. Judging both from the results of the experiments, and from the experience of common practice, it is considered that the most profitable utilisation of town sewage will in most cases be obtained by the application of about 5,000 tons per acre to meadow or Italian rye-grass,"—both of which are most profitably used for feeding stock or for dairy purposes. This however is not the opinion of Mr. Bailey Denton, who thinks that Italian rye-grass is a mistake, and that stock-feeding and dairy-farming are a delusion. In his lecture last year to the Maidstone Farmers' Club on "Sewage Irrigation as a means of disposal of Town Sewage," and in considering by what description of crops the sewage farmer would most profit, he stated "that Italian rye-grass had hitherto held a permanent place; but with this he did not agree," and he gave statistics to prove that generally speaking the cultivation of grass on sewage farms was unprofitable. "Mangolds, beet, turnips, carrots and parsnips, potatoes and cabbages—the latter especially—he recommended as good crops for the sewage farmer;" and he quoted Mr. Petre, of Lodge farm, and Mr. Hope, at Breton's farm, in proof of it. He even advocated "the production of straw upon a sewage farm as a matter of great moment;" for although the quantity of grain was small, the bulk of straw was large, and this was advantageous in feeding stock. "In the main however," said Mr. Bailey Denton, "the less the sewage farmer dealt with stock, and those other branches of farming which were not essential to a sewage farm the better, for he would require all his attention to be devoted to the essential duties of the farm, and the marketing of its regular produce."

---

## SOCIAL SCIENCE CONGRESS AT LEEDS.

OCTOBER, 1871.

SIR JOHN PAKINGTON, President.

WEDNESDAY, OCTOBER 4TH.

THE Association met and the President delivered the Address. It was largely occupied with the question of education, and has excited a good deal of discussion in the daily papers, but we have not space for a report.

## MR. HASTINGS'S ADDRESS.

MR. HASTINGS, the President of the Council, delivered the usual address on behalf of that body, touching at the outset upon the subject of education, after which he turned to the subject of public health, observing upon the importance of the adoption of large areas for sanitary administration, and thus referring to the necessity for employment of efficient officers of health. An officer of health should be paid such a salary as will secure the services of a trained intellect and high character. Being thus remunerated, he should be rigorously debarred from private practice, not only that he may devote his whole time to the functions of his office, but that he should be free from private influence in performing his duty. Such an officer can be obtained by counties, but seldom or never by unions. The rateable area of a county, supplemented as it would be by boroughs which would unite with it for sanitary as they now do for jail and police purposes, can sustain a cost under which the union must break down. It is urged, indeed, that every union must break down. Every union has a medical officer, and it is proposed to place the sanitary welfare of the county in his hands. We protest against such a system. No one has a higher sense of the services and merits of a body of men signally underpaid for their work, denied the social recognition of enrolling themselves in the civil service of the Crown, and struggling manfully in the great majority of cases, though beset with difficulties, to do their duty to the poor. But we cannot believe that these meritorious officials possess the qualifications necessary for sanitary work. It is no blame to them that they have not been trained for duties which require, as our late colleague Dr. Symonds, of Bristol, admitted, very different acquirements from those which are successful in the treatment of sickness; nor is it easy to see how professional men whose time and energies are absorbed in daily toil are to qualify themselves by that study of all sanitary questions which the commissioners recommend as desirable for medical officers of health. Granting them even the necessary qualifications, these poor-law practitioners are under the grave liability of private practice. On that important point I will content myself with quoting from a valuable minute issued by the General Board of Health, dated December 20th, 1855, and signed by the Right Honourable William Cowper, president of the board. That minute deals with the duties and qualifications of a medical officer of health, and says, "It will be well to debar him from the private practice of his profession—Firstly, because the claims of such practice would be consequently adverse to those of his public appointment, the duties of which, especially at times of epidemic disease, when his official activity would be most needed, private practice could scarcely fail to interrupt and embarrass; secondly, because the personal relations of private practice might render it difficult for him to fulfil with impartiality his frequent functions of complainant; and, thirdly, because with regard to the cordial goodwill and co-operation of his medical brethren, it is of paramount importance that the officer of health should not be their rival in practice, and that his opportunity of administrative intercourse with sick families should not even be liable to excuse for the purpose of professional competition." If this reasoning be sound, and much evidence has been collected both in our own country and on the Continent in its support, it follows that the poor-law practitioners, who depend on private practice for their livelihood, are not fitted for the functions of health officers. The questions of pauperism and criminals were next dealt with—it being pointed out that the Association has never ceased to direct its attention to the best means for the repression of crime. In conclusion, he said, let me urge the necessity of cultivating the scientific spirit in dealing with social questions. Wanting that, we are like a ship adrift at sea without a rudder. Science, which in all the ramifications of its pursuit means the reduction of knowledge to accurate form, is the peculiar safety of the legislator, pushed on as he is by blind impulse, and shackled by conflicting interests and the jars of faction. Its value to mankind is well attested by the virulence it awakes in opposite quarters. Science is honoured by the hate alike of those who would return to mediæval superstition and of the party not less fanatical, who would submerge civilisation in a sea of blood. It is, in truth, vituperated by all who find the reality of facts inconveniently in their way. Thus it is the fashion of some to call political economy hard. They speak of it as if it were an active agent in the injuries they suffer or fancy. A few years ago some London workmen, when warned of the unwisdom of their proceedings, replied—"If political economy be against us, we will be against political economy." As well might a

man exclaim, who had fallen from a ladder and broken his leg "If the law of gravitation be against me, I will be against the law of gravitation." Political economy, like astronomy or chemistry, or any other science, does not create facts, but expounds them. In that sense political economy may be bold, for it tells us of hard facts—of realities which nothing can disannul. It is in truth only the rules of common sense and of business experience applied to communities of mankind. Nothing can prevent individuals who are thoughtful and industrious getting the better of the improvident and idle, and nothing ought to prevent it; nor can anything hinder a nation or a society wise enough to obey the laws of nature in their trade from growing more prosperous than those who hamper the growth of their own success by artificial restrictions. Political economy explains these things, and teaches what disasters will follow the defiance of natural principles, but the disasters are not therefore its creation. It is the Communists' dream that they can abolish the forces of civilisation by substituting an automatic society for individual impulse and invention. Do they really believe that the course of the world can be turned back; that man can ever retrograde to the level of instinct, having tasted the prerogative of free will?

"What! can ye lull the winged winds asleep,  
Arrest the rolling world, or chain the deep!"

The human mind cannot be shackled thus. We are not "magnetic mockeries," but spiritual men, and our destiny is rather towards a more expanded and more tolerant civilisation. But to make that progress secure, the idea of individual right and equal justice to all must be supreme.

The Sections met in the usual manner and papers were read and freely discussed. The congress was this year thought by most a success, and it offered a new feature in the Sanitary museum.

MONDAY, OCTOBER 9TH.

## SANITARY SCIENCE.

The President of the Health Department, George Godwin, Esq., F.R.S., reminded his audience that not many years ago there were numbers of educated and influential people who were of opinion that there was no connection whatever between sanitary arrangements and ill-health. At the present time we may, perhaps, go so far as to say that all admit, more or less fully, that this connection does exist. A whole host of questions, however, remain correctly or incorrectly, matters of opinion, and it is with a view of their speedy removal from debatable ground, so that effective action may be at once taken, that this Association holds its meetings and publishes the result of its deliberations. Thus we have ceased to discuss as to the necessity of promptly getting rid of the sewage of towns, but the best mode of disposing of it is still with some a matter of opinion. This part of the enquiry, however, is gradually narrowing; and it may be hoped that the proceedings at this Congress will tend to bring about the right conclusion. In common with a large majority of those who investigated the subject, I feel perfectly assured myself that the irrigation of land is the right use, except in some special cases, to which to apply it. Evidence that it may be thus applied with pecuniary advantage, and without injury to the health of the neighbourhood, is accumulating day by day. Having referred to the new Public Health Bill, now in Sir Charles Adderley's hands, and to the great importance of that part of the Metropolitan Water Act which requires that every company should supply water on Sundays as on other days, the President proceeded thus—The importance of the subject we are considering—the public health—is so great—it lies so entirely at the root of all national progress—that it is impossible to speak too strongly upon it. At the present moment, moreover, it is invested with unusually pressing interest, after a terrible visitation which has desolated homes throughout the country—a visitation which all evidence shows was the result of ignorance, carelessness, and wilful avoidance of a known means of prevention, or, at any rate, of amelioration. We note, at no great distance from our shores, the presence of a much-dreaded disease; and I should be neglecting a duty if I allowed this opportunity to pass without inviting all who have the power to aid in making such preparations as experience shows are calculated under Providence to mitigate its severity. Should we happily escape its visit, we shall still have advantage from the steps taken. When there is no immediate prospect of danger, the cost of precautions is begrudged. A large class of persons would sooner run the chance of death than incur the certainty of having to pay a pound. We are all of us gamblers, more or less, and like to take our chance. The most vigorous and

intelligent action is required on the part of our health authorities, and their hands should be strengthened by public expressions of opinion and outside aid. I am anxious not to be thought an alarmist. There is no occasion whatever for alarm. It is indeed to be strongly deprecated; but it would be suicidal to think, ostrich-like, that if we shut our eyes no one will see us—that if we say nothing about a possible danger ourselves, nothing will be heard of it. The way of victory is to meet it well-prepared. It is now known (says the Registrar-General in a recent report) that where a place is clean, where the waters are pure, where the people are not crowded, where good administrative arrangements are made for the early treatment of attacks in the first stage of diarrhoea, the epidemic is disarmed of nearly all its terrors. But as English towns are still dirty, are dotted over with cesspools, or fouled by bad drains, and the waters—alike of wells and of rivers from which towns draw their supplies—are soiled to some extent by sewage, we can at present expect no absolute immunity, Commissioners and committees have left our water supply much as it was. The hard waters of the rivers are not purified by Clark's process nor are the unpolluted streams brought uncontaminated down to the cities in the plains. Still, much may be done if cholera pursue its customary course by commencing at once all useful works of precaution, so as to mitigate its virulence, and this is what all in their several spheres should aid in doing. After alluding to the unsatisfactory condition of many of the London sewers and to certain sanitary defects in Leeds, Mr. Godwin made the following announcement:—Many of the subjects relating to public health and social progress still offer problems for solution of extreme difficulty, and much good remains undone for want of its being known how best to do it. In confirmation of this, and for other reasons, I am tempted to mention that I have for some time been authorised by an inhabitant in London to state that he is willing and ready to appropriate to the improvement of the health and conditions of the poorer classes of the metropolis a sum equal to that given by the late George Peabody for a similar purpose—or say half a million of money—when he can see a mode of satisfactorily effecting this without fear of pauperising the class he seeks to benefit. Means were taken to make this offer known to a limited extent, and a large number of suggestions have been sent to the proposer, but he is not yet satisfied as to the course that can wisely be taken. We must congratulate that individual on holding in his hand the power to achieve a glorious end, and I would add a hope that a noble example of what may be done by an employer to improve the condition of those engaged for him is to be found in this district. I mean, of course, Saltaire, where intelligence and far-sighted benevolence have provided healthful homes, education for the children, innocent enjoyment and means of culture for all. The time is coming when the history of the result of that establishment in a sanitary and social point of view should be written with a view to the guidance of others. We lose on a moderate computation a hundred thousand lives annually by preventable diseases, and millions of money in consequence of these deaths, and of premature disability in cases where death does not ensue. A million paupers receive relief weekly in England and Wales. With complete study of the laws of health, preventive medicine, and improved sanitary arrangements throughout the kingdom, the number of this melancholy army would soon be materially lessened. I have spoken of disability where death does not ensue. With reference to this, let me say that we want the registration of it. The registration of deaths which is now enforced is of the greatest value, but we need beyond that the registration of sickness, which would show the magnitude not only of the grief and poverty to individuals caused by disease, but of the money loss to the public. The desirability of this is fully recognised by the Royal Sanitary Commission, so that we may hope for legislation before long. The close connection between the absence of proper dwelling accommodation and ill-health having been strongly insisted upon, the President concluded by urging that sanitary science should be taught to all from the earliest years in schools of every grade. Until this be more generally done, we shall go on as now destroying one another, and blind to the fact obvious to a Latin poet 1,500 years ago, that life is not to live but to be well. This great question of health calls for the primary and unremitting attention of statesmen and legislators. It is far above party considerations and far superior in importance to the great majority of subjects which monopolise attention. Without education and health no nation can advance and be happy, and to bring about those conditions should be the chief object of all government.

## Hospital Reports.

### KINGS COLLEGE HOSPITAL.

*Epithelioma of the Penis—Amputation—Enchondromatous Tumour of Finger—Enucleation—Hare-lip.*

(Under the care of H. SMITH, Esq., Surgeon to the Hospital).

THE case of epithelioma of the penis was, Mr. Smith observed one of very great interest, not so much on account of the nature of the operation itself, but because such cases were often extremely difficult to diagnose owing to there being no exact history.

As regarded the operation the only points worth noticing were:—1st. That he had made a bold sweep taking care not only to remove the diseased part but also a margin of healthy tissue, a favourite practice of his as the pupils had had many opportunities of seeing, as such a procedure would, to a considerable extent, prevent the possibility of a recurrence of the disease. 2nd. In these cases the urethra after amputation had a tendency to contract if not to close, to prevent then such an accident, he had slightly opened the urethra at its lower part and stitched either side to the adjoining mucous membrane.

The man stated the disease had been coming on for four or five years, which together with the general appearance of the man, convinced Mr. Smith prior to operating, that the disease was what it had turned out to be, viz., epithelioma, and *par consequens*, he, Mr. Smith, had been perfectly justified in advising the procedure they had witnessed him perform, and the operation he believed would prove a success, the neighbouring glands were unaffected, and there was no hereditary taint.

The next case was a tumour situated on the left ring finger at its metacarpo-phalangeal joint, and from a very careful examination it appeared to be connected with the joint, while the character of the tumour was so imperfectly defined, as to lead the surgeons present—who examined the case—to be pretty equally divided in their opinions as to whether it was fibrous or enchondromatous.

Another feature in the case was, that as the man was a printer, it was highly important his finger should if possible be saved, though from its apparent connection to the joint and adjacent textures, so happy a result was in Mr. Smith's opinion problematical. Mr. Smith commenced his operation by making a longitudinal incision over the tumour, and then carefully explored its connections. Finding he was enabled to pass the handle of the scalpel round nearly its whole circumference. Mr. Smith proceeded to enucleate the tumour by a series of manœuvres in a manner introduced, and practised by Sir William Fergusson, which has already been described in these columns.

The finger was then dressed and a splint applied along the palm of the hand and arm.

Mr. Smith then showed the tumour to the class, and pointed out to them that it possessed all the characteristics of an enchondromatous tumour. In the process of enucleation, Mr. Smith had been able, he was glad to say, to preserve intact the extensor tendon, and if all went well, that is supposing no extensive inflammation of the joint was let up, the man would recover, and what to him as a printer was the important point, without the loss of his finger.

The case of hare-lip Mr. Smith said was interesting in many ways:—1st, as illustrating the fact, that chloroform may be given to very young children—2nd, that these operations can be performed on very young children—the case before them was only five weeks old—3rd, that such operations succeeded better in very young children than in those of a more advanced age, and

that where complications existed, such as cleft palate, the parts more readily came together.

In the present case, he had been obliged to remove a portion of the alveolar process, which whenever possible, it is best to avoid for obvious reasons.

The operation itself presented no features of importance, the complication of cleft palate was unfortunate, but Mr. Smith for reasons above given, might predicate a successful termination and cure.

#### Lithotomy.

(Under the care of ROYES BELL, ESQ., Assistant-Surgeon to the Hospital).

Mr. Royes Bell's patient was then brought on the table and placed under chloroform. A sound was passed, but it was not till after repeated requisitions that the stone was heard and the "click" heard; the operation was then commenced. Mr. Henry Smith holding the staff. Mr. Royes Bell's first incision was scarcely as bold a one as we should have anticipated from a disciple of Sir Wm. Ferguson, in other respects the operation was proceeded with in the usual manner, and on reaching the bladder, the stone was easily extracted with a scoop.

Mr. Bell observed that cases of lithotomy in young children as a rule did well, he believed it was highly important never to withdraw the staff till the stone was felt, and he might add when once you felt the stone with your finger, never to let go of it till it had been seized by the forceps or scoop.

The operation had taken a few seconds longer than usual, which he attributed to his earlier incisions being scarcely free enough. The stone was of the uric-acid variety, and weighed about a drachm and a-half.

The difficulty in detecting the stone in this case—an occurrence not unusual when patients so affected are brought on the operating table—was attributed to the bladder being too full, and the stone consequently slipping about like a piece of soap in a bath.

### THE LONDON SURGICAL HOME.

#### Case of Ulcer of the Rectum.

On Thursday, September 28th, Mr. Baker Brown gave an interesting *clinique* upon the subject of ulcer of the rectum. The particulars of the patient operated upon were given as follows:—

Mrs. P., æt. forty-seven, married, but has had no children. Has ceased to menstruate for the last four years. Four months ago she began to complain of pain and soreness of the cervix uteri, and of a sensation as if a lump were in the vagina. She also suffers from pain in the right iliac region when lying down, and of weakness of the abdominal walls. Bowels irregular. Has had various medical treatment without relief. All her symptoms had been considered as due to uterine disease, both by herself and the medical men. Chloroform having been administered by Mr. Harris, and the patient placed in the lithotomy position, demonstration by the vaginal speculum showed that the os uteri was quite healthy, as also was the vagina. There was slight leucorrhœa. Mr. Brown then passed the tip of the finger into the anus, and instantly detected an ulcer. Other gentlemen who were present then examined the anus by the finger, but failed to realise the presence of an ulcer, the patient being under chloroform. Dr. Edmunds then passed a Gowland speculum into the rectum, and displayed a well-marked circular ulcer on the upper margin of the internal sphincter and towards the right luberischii, precisely at the spot which Mr. Brown had pointed out. On reversing the speculum so as to display the other side of the anus, a well-marked polypus rather larger than a pea, and like a large wart, was seen. Mr. Brown remarked that the occurrence of these polypi with ulcer of the rectum was very common, and he was inclined to think that they

were formed by the ulcer by a process of moulding under the spasmodic pressure of the sphincter. The polypus was seized with long forceps, and cut off with seissors, the spot being afterwards touched with solution of perchloride of iron. The speculum being then removed, Mr. Brown passed the straight blunt-pointed bistoury into the bowel flat upon his right index finger, the point of which was placed on the ulcer. The bistoury being then turned with its cutting edge outwards, Mr. Brown drew out the finger and knife, *en bloc*, cutting freely through the ulcer, and also dividing some half-inch of the integuments from the margin of the anus. The patient being still under chloroform, Dr. Edmunds again introduced the Gowland speculum so as to display the effect of Mr. Brown's operation. The incision had commenced above the ulcer, and passing through its centre had divided the mucous membrane and superficial fibres at the sphincter quite freely. Mr. Brown said that was precisely his usual operation, and that it would certainly cure her. The incision was then filled with lint soaked in perchloride of iron solution, and the patient removed to bed, still under the influence of chloroform.

Mr. Brown remarked that all this patient's uterine symptoms had been dependent upon the ulcer in the rectum, and that this constantly occurred, the patient's uterus being cauterised, and the ulcer in the rectum being overlooked.

A patient was then exhibited who had been operated on for fissured anus, on Sept. 7, at a former *clinique*. She declared herself quite well, and as passing her motions now without suffering of any kind. The following are the particulars:—

Sept. 5th.—Mrs. C., æt. thirty-seven, of Wandsworth, married thirteen years, no children. Has had a complaint in rectum for three years. Had been examined by two doctors, and afterwards (in April) was under the treatment of a Clapham homœopathist. Feels very great pain and plunging when walking, and constant aching of back. Is very subject to fainting and headache.

Sept. 7th.—Mr. B. Brown operated, assisted by Dr. Edmunds. Mr. Harris administered chloroform. Recovered perfectly.

#### Spasmodic Contractions of a Fractured Limb, Arterial Compression.

M. Broca had under his care a few months ago, in the Hôpital de la Pitié, a man who had broken both bones of the leg an hour before his admission to the hospital. The muscular contraction was so violent that it was impossible to reduce the fracture. M. Broca thereon employed a method which he had found successful in several cases of painful cramps of the lower limb—viz., compression of the femoral artery. Almost immediately the muscles became relaxed, and reduction was effected with ease. Subsequently, in re-applying the splints, the contraction returned, and was again overcome by the same means. The *Journal de Médecine et de Chirurgie Pratiques* for March, in relating the case, says that the simple and easy means employed by M. Broca ought always to have a trial before giving chloroform, which is often done in such cases.

#### The Induced Galvanic Current in Ileus.

DR. MACARIO relates in the *Annuario delle Scienze Mediche* for 1870, the case of a man aged seventy, who had long been subject to obstinate constipation, and who was suddenly seized with severe pain in the umbilical region, violent cramps, and abundant vomiting, first of bilious, and then of stercoraceous matters. He was in a state of semi-stupor, with small, weak pulse and singultus. One pole of a Gaiffé's induction-apparatus was introduced into the rectum, and the other was applied by means of a wet sponge to the abdominal wall over the transverse colon. Energetic contractions of the abdominal muscles were produced, and were attended with much pain; but, at the end of ten minutes, the pain and vomiting had ceased. Four hours afterward, the patient had a spontaneous evacuation of the bowels, followed by two others in the course of the night; and the next day he was convalescent.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 18, 1871.

**THE CONNECTION BETWEEN DIVINITY AND PHYSIC.**

IN the person of the Reverend Professor Haughton of Dublin, the Profession has a precedent for the assumption of medical qualifications by a clergyman, but the example of Dr. Croskery, of Jamaica, in assuming the gown and duty of a clergyman, while still practising his Profession as a medical man is, as far as we know, unique.

It is not the first time that medical men have abandoned the practice of medicine and entered the Church, but there has been a veritable change of Profession, and with their devotion to religion their connection with medicine has ceased.

Dr. Hugh Croskery, a Licentiate of the Irish College of Surgeons, and well-known in connection with the medical press in Jamaica, was ordained Deacon on the 17th of last month.

In the course of his sermon, the Bishop referred specially to the fact that Dr. Croskery will, notwithstanding his ordination, continue to exercise his Profession as a medical man, and that the services which he is to render to the Church will be entirely gratuitous. He also pointed out the scriptural authority for ordaining one whose time is partly occupied in the secular duty of healing the sick, and showed that there is no incompatibility between these duties; but, on the contrary, that such a union of offices might be peculiarly blessed. On this subject his Lordship observed:—

"The question of course was seriously considered whether it was allowable or desirable, to sanction the proposed union of ministerial with medical functions; and no reason whatever has been found why one who becomes a Deacon must of necessity cease to be employed as heretofore, in endeavouring to heal sickness and disease; but the contrary, there appears to me to exist many and strong reasons for regarding this ordination with especial satisfaction, and for indulging an earnest hope that the precedent now to be established will be followed.

"It has been supposed, however, that one of the canons of 1603 prohibits such a union of offices, and it is, therefore, important to show that the proposed ordination is contrary neither to their spirit nor to their letter. The canon referred to, the 76th, has the heading 'Ministers at no time to forsake their calling;' and it proceeds to declare as follows:—'No man being a Deacon or minister shall from thenceforth voluntarily relinquish the same, nor afterward use himself in the course of his life as a layman, upon pain of excommunication. And the names of all such men so forsaking their calling, the churchwardens of the parish where they dwell shall present to the Bishop of the Diocese.' . . . It may, however, be contended that the canon indirectly condemns the union of any other office or employment, in anywise of a secular nature, with that of a Deacon or Priest. That this is not so is proved conclusively by the next canon but one, the 78th, which expressly allows that in any parish church, or chapel in which there is a curate, such curate may be licensed by the Bishop as a teacher of children—in fact, as an ordinary schoolmaster; and this, it is worthy of remark, not merely for the training up of children in the principles of true religion; but, says the canon, 'for the increase of his living;' or as we should say, for the increase of his income."

**THE OBSCENE QUACKS.**

THE *Irish Builder*, taking as its text a recent leading article in the **MEDICAL PRESS AND CIRCULAR**, devoted space in a recent issue to a well-spoken appeal against obscene quackery, a denunciation of the newspapers which derive an infamous profit from aiding and abetting the publicity of obscene quacks, and an exhortation to young men and to fathers of families to keep out of sight the abominable hints and suggestive allusions of these swindlers. At the conclusion of the article the *Builder* published a Quack Directory, giving the names of advertising quacks whom it would be proper to avoid, and included in that *index expurgatorius* the title of a certain person named Sylvester—*soi-disant* the Reverend. The *Builder* received by next post the usual quarto communication from an attorney, who, of course, is "instructed," on the behalf of his client, E. Sylvester, Esq., of Willesden, to demand at once an ample written apology, and "that you will also, in your next issue, give such public retraction to your statements as will fully satisfy my client, who is inclined to believe his name may have been inserted through mistake for some other. If you decline to accede to this request, I will be obliged to proceed against you in vindication of my client's character and professional reputation.—I am, Sir, your obedient servant."

But the *Builder* did not draw its sword for the purpose of resheathing it. It considers it a consolation to know that we succeeded in unearthing at last one pseudo-clerical rascal from his suburban retreat in Middlesex. An apology, forsooth—an apology for what?—for scotching one slimy and unclean thing, who, under the garb of religion and humanity, has been fattening for years upon the hidden social ulcers of society. We have to inform Mr. or Rev., or F. Sylvester, Esq., or whatever other *alias* he may choose to designate himself, that we will neither apologise nor retract for one scintilla of our words; and that, though we hail from Ireland, we are wide awake to the plunder carried on by himself and his conrogues in quackery. There is no vindication needed for a "professional reputation" sunk beyond all human

remedy—a reputation and a trade that must stink in the nostrils of all decent society, and a scandal to civilisation, journalism, and the law that allows it to exist in our midst. If this will be sufficient apology for F. Sylvester, Esq., he is most welcome to it.—Ed. I. B.

Since the above was written we perceive by a London contemporary that the real curate of Willesden has written to the papers that there is no such personage known in that town. It appears that the nefarious quack calls twice a week at the post-office for his letters, and sports a carriage and pair in the performance of his calls.

## Notes on Current Topics.

### Scurvy in Paris during the Siege.

DURING the Prussian siege of Paris scurvy prevailed to considerable extent among the German prisoners in that city, among the soldiers and marines who occupied the neighbouring forts, and among the inmates of some of the hospices for aged persons. Of those affected a good many were treated in the Ambulance of the Luxembourg Palace; but the greater number were sent to the Military Hospital at Ivry, where M. Leven had a *service*, and to whom we are now indebted for some remarks on this disease.

He starts with the assertion that neither is the deprivation of vegetable diet in itself a cause of this disease, nor is any special diet or medicine indispensable in its treatment. He believes that the prime causes of the disease are cold, damp, insufficient food with reference to the labour to be performed, and denies as altogether unworthy of belief the theories that insufficiency of the salts of potash or soda in the blood of the subject has anything to do with it. He observes that in northern regions, where the natives have a cold and damp climate, although their chief food consists of potatoes they often become scorbutic. He alludes to the reports by Lind, in one of which an account is given of a voyage of no more than three months' duration, during the whole of which the sailors fed upon salt pork and salt beef without once tasting vegetables, yet no case of scurvy occurred; whereas by another the sailors on board the *Salisbury* had an abundant vegetable diet, yet a large number of them became scorbutic within six weeks. After quoting the opinions of Reynolds and many other writers, that the disease is altogether the result of the absence of vegetables and fruit, and that recovery is only practicable when they can be freely given, M. Leven states that neither are vegetables essential to health as preventives of the disease, nor are they effectual of themselves in its cure; and he mentions in illustration that in the Hôpital d'Ivry he had treated persons successfully by means of fresh meat finely minced, who had previously had, without benefit, syrup of cochlearia, citrons, &c. According to him, patients affected with scurvy, if placed in good hygienic conditions, sufficiently warmed and suitably fed, recover whatever be the kind of diet furnished, provided it be substantial; but that as the circumstance which most retards scurvy is the condition of the teeth and gums, the diet supplied should be of a nature not to demand much mastication.

The patients admitted into hospital do not appear to

have manifested scurvy from the first. During the siege they had had as food bread, rice, horse-flesh, coffee, rum, and a glass of wine at breakfast and dinner daily. This food was sufficient, but it was incapable of maintaining the power of resisting the coldness of the season. If under it a person contracted broncho-pneumonia of a nature to confine him to bed two or three weeks, at the end of that time he manifested symptoms of scurvy; so that although the food was not in itself a cause of scurvy, yet when added to another cause of *denutrition* scurvy became developed, to be cured by broths and meat in sufficient quantity, without the use, as M. Leven states, of either vegetables or medicine. The food of others, he observes, had consisted of potatoes, onions, bacon, yet they became scorbutic, and when taken into hospital recovered rapidly under the free use of soups, eggs, and raw meat. The old men from Bicêtre who suffered from scurvy complained of having been without sufficient means of warming during the great cold of winter, and to have suffered in addition from hunger. Their diet had consisted of 300 grammes of bread, soup-maigre in the morning, a cup of bouillon with a spoonful of rice at midday, rice in the evening with seven centilitres of wine. These men speedily improved under ordinary diet, and, reasoning from such facts, M. Leven considers that vegetables may be dispensed with in the treatment of the disease, adding that the nutritive elements which they contain are to be found in equal quantities in other aliments; but that these aliments if little varied, as in the case of soldiers in a siege, or sailors on board ship, produce dislike and loathing in the persons using them; and salted meats, whether in the case of sailors at sea or soldiers besieged, rapidly impair the digestive functions. They, moreover, become objectionable to the person, and this increases from the impossibility of obtaining any variety. The diet after a time becomes insufficient for its purposes, and thus constitutes one of the fundamental causes of that special inanition called scurvy. M. Leven promises to continue his report on this disease in the *Gazette Médicale de Paris*.

### Falling off in the Food of the People.

MR. EYKYN, M.P., has drawn a very alarming picture of the condition into which England has lately fallen in regard to the supply of meat, and of our prospects in that respect. Speaking before the South Bucks Agricultural Association Meeting, he is reported to have observed that—"It is a serious matter when we consider the food producing power of this country. Since the year 1868 the animal produce of this country stands thus:—The cattle have stood nearly still, there being a slight depreciation. Your sheep since 1868 have receded nearly three and a-half millions or eleven and three-quarters per cent. and there has been half a million to the bad in your pig stock. Now, it is serious to contemplate how we are to provide for an increasing population such as is gathering about us at the present time. The practical minds now present may tend to solve that difficulty." For his own part he considers this very serious difficulty will be met by practical men, for we cannot afford to starve while we have money, and we shall have to pay dearly.

The subject thus presented is indeed a most grave one taken in reference to its bearing upon public health. The existing and prospective scarcity and consequent dearth of animal food will necessarily diminish the

quantity for daily consumption among many thousands of the population, and in the case of many thousands more will absolutely deprive them of it altogether. Unless, therefore, something be done, and that speedily, to import cattle and sheep upon a large scale, the prospect we at present have simply amounts to this, that increasingly large numbers of the people will suffer from insufficient food, and that the prevalence of diseases attributable to famine will increase.

### Offences under the Vaccination Act.

At the Manchester Police Court, Henry Jones, green-grocer, appeared in answer to a summons under the 29th section of the Vaccination Act, for neglecting to submit his child to the examination of the public inspector after vaccination.

Having heard the evidence, the clerk to the justices said that the prosecution had not proved that the child had been vaccinated, and therefore, as he read the Act, there was no case. The magistrate took that view and dismissed the case. At the same court a boot and shoe maker was summoned to show cause why he should not allow his child to be vaccinated. The defendant on being asked what he had to say against the magistrates making an order, replied that it was scarcely worth while making any defence. The only course to him was either to obey or pay. He had plenty of reasons for not having the child vaccinated, but, unfortunately, no reasons were accepted as legal except that the child was unfit. He objected to vaccination upon principle. Mr. Higson said that was not a legal defence. The magistrates decided to make the order.

### Lunacy.

In a notice of German literature in its usual interesting psychological retrospect, the *Journal of Mental Science*, observes that it is to be remarked that the transition of opinion from belief in restraint to that in non-restraint, is gradually proceeding in Germany. A good delineator whose remarks on English asylums will be presently referred to, brings forward a feature of the asylums in our country, which must be more frequently introduced on the Continent before restraint can be finally abolished, viz., the construction, as part of each asylum building, of a good many single rooms, for the isolation of unruly patients. Our contemporary then passes to a consideration of some recent articles, and says:—

“The author's comparison of the provision made in England with that made in his own country is very flattering to the former. In the course of the paper Dr. Meyer gives in his adhesion to the belief in the increase of mental diseases in modern times. His main end is to show the advantage of placing in ‘colonies’ the chronic harmless insane, so that they may have as much as possible a domestic mode of life, and at the same time so that the State should find them as little expensive as possible. Following on this, a paper by Dr. H. Nothnagel, on ‘The Trophic Lesions in Neuralgia,’ after putting aside the assertion of mere want of exercise as the cause of atrophy in neuralgia, and declaring the presence of trophic nerves to be so far hypothetical, conducts to the conclusion that the ‘simultaneous sharing of the vasomotor nerves’ in the neuralgic process is to be regarded as the cause of the atrophy. Dr. Julius Sander relates some cases of aphasia, without supporting any particular theory of the disease; and Dr. Thomas Simon, of Hamburg, brings forward a

case of ‘maculose (fleckweise) vitreous degeneration of the cerebral cortex’ in a female—not the subject of any mental disease—who had been of very haughty disposition, but had died after long residence in a poorhouse.

A little further on we are told that—“Dr. Thos. Simon, of Hamburg, has two contributions—one in this Part, and the other in Part II.—to the pathology of paralytic dementia, as far as regards the spine. He gives the history and *post-mortem* appearances of twenty-six cases in the fullest and most satisfactory manner. His researches bear especial reference to the presence in the cord of a certain sort of myelitis, characterised by the presence of granulated cells (Kornchenzellen-Myelitis), and his conclusions are mainly of a negative sort. Thus he finds that these granulated cells are not more frequent in the spinal cords of general paralytics than in other spinal cords. Such an abundance of these cells as to point to an antecedent myelitis, is rather a rare occurrence according to Dr. Simon; but that, too, is not characteristic of paralytic dementia (the last stage of general paralysis of the insane), since it occurs in other diseases. The tendency of the whole paper is to unite dementia paralytica with chronic alcoholism and other affections. One ground of union between these diseases is, that all of them are found at times as results of inflammation of the dura mater (pachymeningitis). Among the reports appended to this part of the ‘Archiv.’ there is one of a meeting of the Swiss medico-psychologists, at which votes were taken for and against non-restraint. The meeting was very decidedly in favour of the non-restraint plan. In the meeting of the Berlin Society, here reported, a discussion on a subject above referred to, took place, viz., as to whether the conception of ‘free will and accord,’ or that of mental sanity or insanity should be the ruling one in law-giving. A lawyer, who took part in the discussion, maintained that when the medical jurists had to pronounce upon the presence or absence of true volition, in the criminal act, he really decided on the sanity or insanity of the individual; but this statement was not accepted by the medical men present; they maintained that in setting to the expert the problem of the voluntary or involuntary affection of the agent in the time of the act, the law put him on just the same level as any layman, the latter being quite as able to solve this problem as the expert.”

Passing to another paper the journal says:—“In Part Second of the second volume of the ‘Archiv.’\* there is a very elaborate and important paper by Dr. Rudolph Arndt, of Greifswald, on the employment of electricity in alienist practice. At the commencement is a good sketch of the history of electro-therapy, beginning from the times when the negroes were wont to place their sickly children in the favourite haunts of the electric fish, in order to cure them. Dr. Arndt lays great stress upon the work done in modern times by Remak. The alternate rise and fall of the treatment by electricity in the estimation of physicians is well depicted. From the time of Volta, up to about the year 1800, there was a rise in its popularity; after that there was a decline till the work of Faraday, about 1830, began to retrieve the fortunes of the method, though it did not rise to eminence among the resources of medical art till the labours of Duchenne, in 1850, were made known. These were capped by Remak's researches. The rotation apparatus† was that first used in asylum practice, and it was employed for all sorts of purposes, till it degenerated into a mere instrument for stimulating and terrifying the patient. Occasionally, nevertheless, good results were got; often very bad results, and a case of the latter sort is given by Dr. Arndt. The reputation of the method declined and the discovery of contact electricity did not do much to stay the downward progress. Teilleux and Anzuouy, in France, still reported favourably on the subject. A number of cases where voltaic electricity was used by the former are quoted by the writer. Teilleux applied the current to nerves and plexuses near the surface of the body. Anzuouy

\* 18 0.

† For Franklin electricity, i.e., the old electrical machine.

had a theory that the skin was a very important tissue in the insane, and he used magneto-electricity\* to arouse its functions. At this stage Dr. Arndt selects for narration two cases treated with the induced current. In both there were favourable results; but in numerous other cases the results were unfavourable. 'After all this experience,' he then says, 'I thought myself driven to the conclusion that the induced current, as usually employed, exercised a strongly irritating influence on the diseased central organs, and that it was, therefore, contra-indicated in all those cases of psychical ailment in which the symptoms present had in themselves the character of augmented irritability, or could be referred to the same state in the region of some nerve. In all so-called primary cases, then, in which a state of irritation of the brain has shown itself by the dominance of passions, whether positive or negative in character, its employment must be abstained from. Likewise, it must be laid aside in all those secondary cases which are marked by a high grade of weakness with irritability, and tendency to reflex action. It may answer as a curative agent only for those cases which are marked by mere abdication of the brain's activity, by simple depression or paralysis of the functions.' He thinks Faradization of the skin and of the phrenic nerves important. A case is given of a girl eighteen years old, who had severe chorea with intervals of dementia; the dementia gained ground, and became continuous; now and then there appeared slight erotic tendencies. Faradization was employed to the arms, legs, phrenic nerves, and face. There was improvement after each application, which lasted two days at first, but gradually got more protracted. The sensibility to the current was nothing at first, but increased to a great extent as she got better. The face became pale and the pupils dilated during each *séance*. There was in this case no hereditary tendency to insanity. Another case is one of dementia, after long nursing a child through fever. A third is one of utter absence of mind in a young girl, alternating with fits of terror. The girl was very nervous, and a fright originated the psychical affection. She got quite better under Faradization. Of such cases Dr. Arndt gives seven in all. On them follows a minute consideration of the effects of the constant current, and a discussion on anelectrotonus and katelectrotonus, on the direction of the current in the body, the proper position of the poles, &c. In assigning to the induced and to the continuous currents their appropriate uses, Dr. Arndt alludes to the element of convalescence, probably present in the above-mentioned cases, and which he believes it was the part of Faradization merely to call out by its irritant action; he points to the constant current as the only agent which can really modify nutrition. The negative pole of the latter is to be used when it is wished to arouse irritability in a part, and the positive when this quality has to be diminished. The path of the electric current in the body, Dr. Arndt maintains, is the *resultant between shortest distance and best conductors among the tissues*. For the mode of passing the current through the brain, the writer refers to a paper by Erb, in the *Deutsches Archiv für Clinische Medicin* (vol. iii., 1867). To subject the spine to the current, one pole should be placed on the spine, the other on a limb, so that a part of the anelectrotonus or of the katelectrotonus coincides with the spine. The spine should, it is maintained, often be the object of galvanization, because it is very often the source of evil in insanity. Peripheral galvanization is to be used where a neuralgia began the mischief, or where there were decided peripheral symptoms at first."

— In a speech delivered on the anniversary of the foundation of the University of Berlin, Dr. Bruns, the Rector, stated that 700 students of Berlin and 400 from the Leipzig University had been engaged in the French campaign, of whom 88 received their deaths either in war or by disease.

\* "Faradaic" or "induced" electricity.

## Play for the People.

UNDER this title the Victoria Press has issued a pamphlet "On the National Importance of Teaching," and enabling the people to play rationally and healthfully, as illustrated by the Alexandra Palace. It contains the substance of a paper read by Mr. F. Fuller, and of the discussion that was thereby excited.

## Health of Dublin.

IN the Dublin registration district the births registered during the week ending 7th October, amounted to 125. The average number in the corresponding week of the years 1864 to 1870 inclusive, was 148. The deaths registered during the week were 134. The average number in the corresponding week of the previous seven years was 138. Five deaths from small-pox were registered during the week; they all took place on the north side of the River Liffey. Scarlet fever caused 4 deaths, diphtheria and whooping cough 1 each. Three deaths were referred to fever, viz., 1 to enteric or typhoid and 2 to simple continued fever. Diarrhoea proved fatal in 12 instances, showing a decrease of 9 as compared with the preceding week. Five deaths resulted from convulsions. Bronchitis proved fatal in 8 instances, and pneumonia in 3. One death was ascribed to apoplexy, and 2 to paralysis. Eleven persons died from heart disease unspecified, and 1 from aneurism. Liver disease unspecified was the cause of 3 deaths, and hepatitis 1. Kidney disease and Bright's disease each caused one death. Twenty-four persons fell victims to phthisis, 6 to mesenteric disease, 5 to hydrocephalus, and 3 to scrofula.

### QUARTERLY SUMMARY.

*Births.*—In the Dublin district the number of births registered during the last quarter 1871, amounted to 2,081, a ratio of 1 in 37, or 27 in every 1,000 of the population. In the suburbs, the number of births was 344 or only 1 in 47. There were registered in London during the same period 33 in every 1,000 of the estimated population; in Glasgow 37 per 1,000; and in Edinburgh 33 in every 1,000. *Deaths.*—The deaths in the Dublin district during the quarter amounted to 1,525, affording an annual ratio of 1 in 51, or 20 in every 1,000 of the population. North of the Liffey 1 in 47; and south of the river 1 in 49. In the suburbs the deaths registered were 252, 1 in 64 of the population. The deaths in Belfast represent 22 in every 1,000 of the population; in Cork 18 per 1,000; in Limerick 24 in every 1,000; in Waterford 29 per 1,000; in Galway 22 per 1,000; in Sligo 13 per 1,000; and in Londonderry 14 in every 1,000. The number of deaths in London during the same period was equal to 23 in every 1,000; in Glasgow 30 in every 1,000; and in Edinburgh 1,217, 24 in every 1,000. *Diseases.*—The number of deaths from diarrhoea amounted to 121, or 1 in every 12.6 of all the deaths. The mortality from diarrhoea was less by 47 than in the corresponding quarter of last year. Phthisis was the cause of 230 deaths, or 1 in every 6.6 of the total deaths. One hundred and thirty-one deaths, or 1 in every 11.6 were ascribed to convulsions. Fever caused 79 deaths.—28 were stated to have been typhus, 37 typhoid or enteric, and 14 simple continued fever. Of all the deaths registered during the quarter 1 in every 19.3 resulted from fever. Seventy-four, or 1 in every 21 of all the deaths, were ascribed to bronchitis, and 27 to pneumonia. Forty-five deaths were caused by scarlet fever, against 92 in the

corresponding period of last year. Croup proved fatal in 27 instances. Twenty deaths from small-pox were registered. Fifty deaths were referred to heart disease, 6 to aneurism, and 1 to pericarditis. Liver disease caused 23 deaths, jaundice 4, and hepatitis 3. Fourteen deaths were referred to kidney disease unspecified, 7 to Bright's disease, and 1 each to ischuria, nephritis, cystitis, and stone. Mesenteric disease caused 29 deaths, hydrocephalus 31, and scrofula 15. Cancer killed 44 persons. Thirty deaths were ascribed to apoplexy, and 21 to paralysis. Thirty-four deaths resulted from violence, viz., 30 accidental, 3 homicidal, and 1 suicidal.

### Re-Organisation of the Army Hospital Corps.

THE *United Service Gazette* understands that steps are being taken to at once carry out the recommendations of a Committee which was appointed about a year ago to re-organise the system of Army Hospitals. Some of the minor and more unimportant suggestions of the Committee have already found their way into the regulations, but the whole point of the recommendations lay in the establishment of a complete Hospital Corps such as we have never had before. To carry out this view the Regimental Hospital serjeants are to be transferred to the new corps, and a new class of officers of a subordinate kind, something like the old medical clerks, are to be appointed for service in hospitals having a minimum number of 200 beds. We believe that it is the intention of Mr. Cardwell to appoint a staff officer to superintend the corps, like the Army Service Corps has, and that a Deputy Inspector-General now serving at head-quarters has already been nominated to fill the post. Although preparations are being made to carry out these sweeping changes in our hospital constitution, we imagine that nothing final can really be effected until the commencement of the next financial year, as the present estimates are not framed to meet the more than probable increased expense. It is in contemplation to offer the subordinate commissioned appointments referred to in the first instance to the assistant-commissaries of the Control Department, who are super-numerary to the list of officers of the late Parveyors' Department.

### Spread of Small-pox in Belfast.

THE hospital return submitted to the Belfast Board of Guardians at their last meeting shows that small-pox is spreading to an alarming extent in that city. There were sixty-four cases in the workhouse hospital against forty-five on the previous Tuesday, and it is believed that the disease is rapidly spreading throughout the town. With the object of preventing persons leaving the workhouse until there is no danger to the public health in their being discharged, it was unanimously resolved by the Board that the Lord Lieutenant be requested to give an order authorising the master of the house to detain small-pox cases until they are perfectly recovered, and that, pending the receipt of that order, no discharges be permitted till next board day.

### Hospital Extension by Working Men.

BARONESS BURDETT COUTTS has been invited to lay the foundation-stone of the Working Men's Extension Wing of the Queen's Hospital at Birmingham. The

ceremony is expected to take place about the end of this month. A sum of £5,000 has been raised in three years by the periodical contributions of 20,000 workmen in the principal factories of Birmingham, for adding this wing to the Queen's Hospital.

### The Profession in Spain.

FEW things are more characteristic of the self-complacency of our medical contemporaries than the ignorance they exhibit as to matters abroad. It is to us incomprehensible that they should be content to pick up any loose information floating about in English daily papers, and dress them up as original matter. We have so often had to correct them, and are so weary of their inability to comprehend anything outside London, except a few paragraphs they pick up from exchange journals, that we had resolved to let them go on blundering in their usual way. We must, however, say one word for Spain. A few weeks ago the *British Medical* congratulated Spain on forming an Association. This is rather strange to us, who attended the meetings of one more than twenty years ago, and know that this and several others are still flourishing.

But last week the *Lancet* made a most virulent attack on the Profession in Spain, which is as unjust as it is untruthful. Taking its information from the *Cornhill Magazine*, it merely echoes the opinions of a literary gentleman that must have been formed years ago. The Profession in Spain is represented as most exclusive, especially towards English. No greater libel could be penned. Again, we are assured that "an English professional brother is allowed the fair value of his diploma nowhere throughout the Peninsula!" This, as will be seen by what we shall state, is now quite untrue. The University of Madrid is at this moment one of the most liberal in Europe, and the present is a most inopportune time for such accusations, as greater reforms have been accomplished in the Peninsula of late years than in almost any country.

But let us take the greatest charge ventured by the writer in the *Cornhill*, and quoted, with approval, by the *Lancet*. Here it is:—

"A case of this sort has come to our knowledge, where the envy of the local faculty and of the local university has been excited for years against an English surgeon doing good service in their own city, and (here lies the sting) preferred by their own countrymen to themselves. When Spanish doctors fled from an epidemic, the English doctor remained. When they wrung heavy fees from the poorest of their countrymen, he spared the lean purse of the toiling and needy. So they have persisted (in the teeth of the English certificates) in recognising him only in the lower walks of the Profession, and he has been repeatedly forced to pay money in fines for the grievous offences of saving Spanish life, relieving Spanish suffering, and excelling Spanish doctors."

Now, whatever may have been the case in days gone-by, it may safely be stated that such a case as this is impossible. We laughed to read it in the *Cornhill*, and did not dream that medical papers would be taken in by it. What is the fact? This oppressed English surgeon or any other qualified man has nothing to do but take his diploma to the University of Madrid and demand to be admitted to examination. The only delay that can legally take place is a sufficient number of days to allow the inquiry by post whether such diploma be genuine. How many of our corporations or universities are as liberal as

this. Would Oxford, Cambridge, London, Edinburgh, or St. Andrew's admit a graduate of a foreign university to examination merely on presenting his diploma? Assuredly not. The oppressed surgeon in question, then, either does not know the law, or the case occurred long ago, or he has not taken advantage of the law. If he has no diploma to present, we presume even the *Lancet* is not prepared to carry its hostility to Spain so far as to claim for him any privilege.

We think we have said enough to show how wrongly Spain has been accused so far. The sneer about Spanish literature is equally baseless. Our contemporary pretends that all are "translated or compiled from the French," and that German or English are apparently inaccessible to them. This from a medical journal so exclusively English is really too bad. Our contemporary ought to know that the best Spanish medical journal, *El Pabellon*, gives more foreign matter to Spaniards than it affords of such material to Englishmen; that its staff speak English very fluently, as we found out when we were in Spain; and that the several Spanish journals give an account of what passes both in England and Germany. As to true liberality of sentiment on all great questions, commend us rather to the *Pabellon* than the *Lancet*; and the same unfavourable contrast may be made in reference to consistency.

We happen to know that the *Pabellon* was the instrument of the great reforms that have been effected, and we therefore think it right to enter our protest against the injurious calumnies that have been circulated.

### Homœopathic Chemists and the Pharmaceutical Society.

A DISCUSSION on this subject took place at a recent meeting of the Pharmaceutical Council.

It was moved:—

"That the two registered chemists and druggists be elected members of the Society:—

"Mr. Groves objected to their election on the ground that they were homœopathic chemists.

"Mr. Williams did not think they ought to draw a line and say they would not admit homœopathic chemists. Many of their members sold homœopathic medicines; and it was a most absurd thing that he should not be a member of the Society when some of his assistants were pharmaceutical chemists or chemists and druggists.

"Mr. Edwards asked if there were any homœopathic chemists members of the Society.

"The Secretary said he believed not.

"Mr. Groves said the Society was one of pharmaceutical chemists; these men did not use the same pharmacopœia or the same drugs, nor had they anything to do with the Society. They might as well admit hydropathists.

"Mr. Edwards said the Act made a great distinction between matters for the public benefit and matters affecting their own internal arrangements as a Society. If a man passed a certain examination he was entitled to call himself a pharmaceutical chemist, and have all rights accruing to him as such, but making him a member of the Society was optional.

"Mr. Bottle read clause 18 of the Act, 1868,—'Every person who at the time of the passing of this Act is or has been in business on his own account as a chemist and druggist as aforesaid, and who shall be registered as a chemist and druggist, shall be eligible to be elected and continue a member of the Pharmaceutical Society according to the bye-laws thereof.'

"Mr. Betty thought, under the words of the eighteenth clause, they were morally bound to elect any

properly-qualified person, because he recollected there was a long discussion on the meaning of the word 'eligible' prior to the passing of the Act, and Mr. Sandford, the then President, stated that that word meant that there was a moral right in the persons referred to to be elected.

"The motion was then put, and the following division took place:—

"For—(5)

"Against—(6).

"The motion was therefore lost."

The Council of the Pharmaceutical Society acted wisely and consistently in refusing admission to homœopathic chemists. They could not affiliate such persons without ceasing to be what is usually understood as a Pharmaceutical Society—a Society for regulating pharmacy as represented by the British "Pharmacopœia." It would be as rational for the Church of England to admit dissenters who abhor its doctrines, as for allopathic chemists, to confer a degree of pharmacopœia chemists on persons who despise and discredit the "Pharmacopœia."

### Cauterisation of the Uterus.

DR. GILLESPIE, of Boston, says that, in place of employing the pencil of nitrate of silver or some other caustic, he takes a common sponge, impregnates it with wax, rolls it in the powdered nitrate of silver, and then introduces it into the uterus, either in the neck or as far as the fundus, using the speculum to do so; he has found no remedy more rapid or sure in chronic inflammations, engorgements, or ulcerations of the mouth of the womb or the cervix.

### Infanticide.

DR. BROCHARD says, "Let us cease to occupy ourselves so much with animals and pay a little more attention to children. Let us re-establish the *tours* in order to diminish the number of abortions and infanticides always increasing. Thus, modern philanthropy will each year save more than 100,000 newly-born children, which die now in the communes of hunger, misery, and want of care and surveillance." We don't think the *tours* would do much good.

MISS JEX BLAKE has been presented with £1,030 by 265 contributors to the fund for defraying the expenses incurred by her in connection with the recent trial. There is a surplus of £112 remaining after paying the legal claims, and this sum Miss Blake adds to the funds already collected for the proposed Hospital for Women.

THE ninety-ninth Session of the Medical Society of London opened on Monday last, the 16th inst. The Fothergillian Gold Medal, value twenty guineas, is offered annually for a dissertation on some subject connected with medical science. The subject selected for competition in 1872 is on Cancer. The learned of all countries are invited to become candidates.

AT the meeting of the Queen's University in Ireland for conferring of degrees, held on Thursday last at Dublin Castle, the degree of M.D. was conferred on 61 candidates, of whom 37 were from Belfast, 11 from Galway, and 13 from Cork. 42 candidates received the degree of M.Ch., of whom 21 were educated in Belfast, 10 in Galway, and 11 in Cork. Ninety students had passed the first examination in medicine.

MR. KIERNAN, the writer whose name is so universally and honourably identified with the physiology of the liver, has presented his invaluable museum, rich especially in preparations of that organ, to the London College of Surgeons, of which he was for many years a member of the Council. This acquisition by the public of this most valuable and interesting collection is a subject for great satisfaction, and occasion for gratitude to the donor.

A HANDSOME tablet has just been placed in the Derry Cathedral to the memory of the late Thomas Henderson Babington, Esq., M.D. It bears the following inscription, in early English characters, surmounted by the arms of the Babington family:—"In memory of Thomas Henderson Babington, M.D., F.R.C.S.I., M.R.I.A., surgeon of the county Londonderry Infirmary, Mayor of Derry, who died 2nd August, 1869, aged fifty-six years. His medical brethren in this city and neighbourhood have erected this tablet in testimony of their affectionate regard for him as a friend; and as a record of their appreciation of his distinguished professional attainments and eminent public services."

DR. DANIEL TUKE continues his observations "On the Influence of the Mind upon the Body," in the new number of the *Journal of Mental Science*. After a number of interesting illustrations, he lays down the following conclusions:—

1. Thought strongly directed to any part tends to increase its vascularity, and consequently its sensibility. Associated with a powerful emotion, these effects are more strikingly shown. And, when not directed to any special part, an excited emotional condition induces a general sensitiveness to impressions—an intolerance of noise, for example, or cutaneous irritation.

2. Thought strongly directed away from any part, especially when this is occasioned by emotion, lessens its sensibility. The activity of the cerebral functions during deep intellectual operations, excludes consciousness of the impressions made upon the sensory nerves generally, and an absorbing emotion effectually produces the same result.

3. The emotions may cause sensations, either by directly exciting the sensory ganglia and the central extremities of the nerves of sensation, or by inducing vascular changes in a certain part of the body, which changes excite the sensitive nerves at their peripheral terminations.

4. There is no sensation, whether general or special, excited by agents acting upon the body from without, which cannot be excited also from within by cerebral changes (including those associated with emotional excitement) affecting the sensory ganglia.

M. GILLE has published in the *Archives Médicales Belges*, an interesting article "On the Value of a Disinfectant," in which he says we must not only get rid of offensive smells, but of all other products of decomposition, and that any substance which only effects one of these ends, is a very imperfect disinfectant. He then passes in review some of the disinfectants in common use. Sulphate of iron he considers is useful from its effect of decomposing ammonia, carbonate, and sulphohydrate. Perchloride of iron, besides this, precipitates albuminoid matters, and acts also by its chlorine. Lime disinfects organic matters, fixing carbonic acid and sulphuretted hydrogen, and decomposing hydrosulphate of ammonia. The permanganate of potass is a most energetic oxidising agent, decomposing sulphuretted hydrogen, destroying organic matter, and act-

ing upon all fixed compounds with which it comes in contact.

It may be remembered that M. Decaisne employed it in dissecting rooms, but that M. Gosselin in 1864, reported that it was not adapted for this purpose. Chlorate of potass may be used to disengage chlorine in places that are not easy to reach by other means. This is a capital plan for cesspools and middens.

Chloride of lime acts by the chlorine it sets free, and chemically decomposes most foul gases. M. Decaisne considers it the best disinfectant of offensive gases. Does it also, mixed with metallic oxides, act by disengaging oxygen as has been asserted? M. Gille doubts this. He also observes that, although chloride of lime destroys offensive gases, it does not arrest putrefaction, but by the lime set free, hastens the process.

Hydrochloric acid is employed to disinfect dog-kennels. Vessels containing it left open, completely destroy the offensive gases that abound where a large number of dogs are kept. This plan is adopted in the Veterinary School of Brussels.

The action of carbolic acid, M. Gille says, is not chemical. He accepts what is commonly called the germ theory, inasmuch as he says the acid prevents germs from provoking putrefaction. He also thinks it will hinder the formation of miasms, and is, therefore, a good preventive of epidemics. It is thus to be seen that all the disinfectants are good, but that they should be used with discernment, a selection being made according to the products we wish to get rid of.

In a discussion that took place at an earlier date in Paris, M. Dumas said the acid had been employed since 1866, by the *pompes funèbres*. It was also observed that this substance was first used as a preventive of cholera at Marseilles.

## THE SANITARY EXHIBITION AT LEEDS.

[FROM OUR OWN CORRESPONDENT.]

THE Exhibition of Sanitary Appliances, held at Leeds during the sitting of the Social Science Congress, was exceedingly interesting, but did not meet with the notice it deserved, either from the Congress officially or in the columns of the general press. While the Congress talked, and the newspapers inserted the speeches of theoretical sanitarians by the column, the results of the labours of those who have turned theory into practice were lying in the Old Cloth Hall almost unheeded by talker or journalist. As the admission was free, large numbers of the working classes and general public of Leeds inspected the numerous and clever contrivances for protecting health that were exhibited, and many of them, no doubt, became acquainted for the first time with the word sanitation.

Water-closets—among which Hall's patent, without valves, deserves mention—dry-earth and ash-closets, sawdust-closets, and many other arrangements for dealing with human excreta, were exhibited, chiefly in the yard of the Cloth Hall. Mr. Colbram, of Burnley, is quite justified in manufacturing cess-pools of one huge piece of earthenware, so important is it to avoid a single chink through which liquid matter can percolate and pollute the sub-soil. Filters were numerous, but presented no novelty worth mentioning. There was a great variety of cooking ranges, all more or less costly to buy, and economical to use.

Among the numerous models and plans for ventilating, Messrs. Benham and Sons' elegant ventilating globe gas-light, and Mr. John Milne's parlour-grate, that draws its supply of air direct from outside the house and sends a current of warm air into the room besides, may be noted. Mr. Cousins, of Leeds, showed a model of a sanitary window, the sashes of which are moved up and down easily, but very slowly, by means of a key, in shape like a winch-handle. When the key is withdrawn the sashes refuse to move, and may thus be left open a few inches for ventilation without fear of house-breakers. That it should occur to any person that an arrangement resembling a windlass would be an improvement upon it, is surely the greatest sarcasm on our clumsy English guillotine window. Why is it that the common French window is still looked upon with awe as a luxury fit only for a drawing-room floor in Piccadilly?

Drawings were exhibited, and also some very pretty and complete toy models of the double-faced cottage—a form common in manufacturing districts, but which has been condemned to some extent as unfavourable to ventilation. It is, however, comparatively easy for sanitarians to deal with the habitations of the rural poor: a problem even more deserving of attention would be, how to provide the wretched lodgers in our densely populated towns with kitchens in which food could be decently cooked. In the whole range of savagery is there a being worse off, sanitarially, than the denizen of the London "three-pair-back"?

A show-case that attracted much notice, and deservedly so, was that exhibited by Dr. Muter, of the South London School of Chemistry. It contained specimens of food, purchased in the poorest districts of the metropolis, and adulterated in the most abominable manner. Quantitative analyses, proving laborious research, both in the laboratory and with the microscope, were affixed beside the samples. We understood that Dr. Muter sent these specimens for exhibition at the particular request of the Committee, and we are happy to see that the authorities all over the country are gradually awakening to the importance of taking steps to prevent the nefarious practices of dealers in provisions; practices which almost exclusively victimise the poor, and tend to undermine the health of the over-crowded and fever-stricken masses who are the least capable of resisting the effects of unwholesome diet.

Kitchen-range boiler explosions are most unsanitary, and Messrs. Rosser and Russell, of London, have done well to exhibit a little contrivance that effectually combats their terrible effects. If a boiler must explode, argue these gentlemen, let it explode in a decorous and regular manner by bursting the thin disc of copper which they screw on to it at a part where the rush of steam can do no harm. These explosions, we are informed, invariably occur in winter, through the freezing of the water in the feed-pipes. It would be a simple plan, too, to place the pipes out of reach of frost.

Spiers and Son, of Oxford, showed some capital "Cyclo-pian washstands." Their soap and brush dishes have no covers, which is an economy as well as an advantage. There is nothing nastier than the ordinary way of keeping soap and tooth brushes moist in covered dishes.

Some beautifully-made models of an exceedingly well-contrived apparatus for ventilating and flushing sewers were exhibited by Mr. Samuel Harrison, civil engineer, of Liverpool. This is a most important and difficult subject to deal with; and it seemed to us that Mr. Harrison has

done all that is possible by means of traps, sludge boxes, sluice gates, &c., to keep sewage under control; and all that can be accomplished with such an inadequate agent as charcoal to purify the gases as they escape at the gully-holes. The system is very complete, and the inventor is entitled to great praise for the pains he took to illustrate it.

Amongst antiseptics, we were surprised to see carbolic acid put in such a poor appearance, Messrs. Calvert and Co. alone showing a few specimens of exceedingly fine quality. The much-advertised chloralum was represented, but our old friend Sir William Burnett's fluid, which is still quite unequalled as a powerful antiseptic, was conspicuous by its absence.

Chloride of lime, that king of disinfectants for out-door use, was nowhere to be seen; so that disinfectants proper—substances that actually decompose and destroy the dangerous products of putrefaction and contagious matter, were represented by Condry's fluid alone. Messrs. Condry and Co. exhibited various interesting apparatus for testing the purity of the air, and detecting organic contamination in water by their very simple permanganate test; and the illustration of the water test, by means of two large glass jars, was particularly interesting at a time when the purity of our water supplies is so much in question. One of the most useful appliances in the Exhibition was the little steam spray producer (Dr. Siegle's), shown by the same firm, for rapidly purifying and disinfecting the air with Condry's fluid, dispersed in the form of spray. We saw this instrument at work, and must say we think it invaluable for oxygenating the close atmosphere of the sick room, or for supplementing deficient ventilation.

Mr. Gerrard exhibited a very simple disinfecting apparatus, consisting of an endless towel revolving on rollers, and which seemed well adapted for use with any disinfectant that purifies the air.

Condensed milk made a good show. The attendant busied himself diluting the paste in tumblers and offering it to the public. The popularising of this substance will benefit the inhabitants of large towns, who have hitherto been at the mercy of the milkman; and for tea, coffee, custards, &c., where sugar is required, condensed milk is extremely useful; but it is incorrect to call it pure milk; it is mixed with a very large proportion of sugar. The saccharine matter cannot be separated from the milk, and it is a serious question whether such large quantities of sugar should be administered to infants. Carelessness will, we fear, prevail in diluting the paste, which is thick and sticky and difficult to measure out to given proportions of water.

Two different exhibitors showed wall papers, but what relation there exists between the mural clothing of the modern dwelling of civilised man and sanitary matters, it would be hard to define. As no special disclaimer appeared to the contrary, we are justified by late revelations, from which it appears that no wall papers are now made without arsenic, in considering their presence at a sanitary exhibition as at least anomalous. Many other objects were exhibited whose connection with sanitary matters is not very clear; but some of them were so interesting that we might be inclined to dwell upon them did our space permit of it.

It is with regret we are obliged to cut short our article of an exhibition which was most interesting to sanitarians, and which did great credit to the spirit of enterprise of its authors, Dr. Robinson and his coadjutors, but with the time at our disposal, we found ourselves quite incapable of

grappling with the details of even a tithe of the 248 articles enumerated in the catalogue. The report or memorandum on the objects exhibited, which Dr. Hardwicke has undertaken to draw up, is no light task, and we trust he will be able to do the exhibitors justice, and throw aside that bias in favour of particular articles which is peculiar to those who systematically lend their names to testimonials and advertisements.

## Literature.

### LARYNGEAL GROWTHS

It would be impossible to name a subject that has of late years made more rapid and satisfactory progress than that of growths in the larynx. Since the introduction of the laryngoscope many diseased states that were most obscure have been made familiar, but none have been more completely placed within our grasp, both as to diagnosis and treatment, than the one of which Dr. Morell Mackenzie here gives a systematic exposition,\* and which we commend to the diligent study of all who are desirous of acquiring a knowledge of the subject. A writer who tells the history of one hundred cases of this kind treated by himself makes a valuable contribution to clinical medicine and surgery, and we might have been glad to receive it at his hands. Our author has, however, greatly enhanced the value of his work by adding an analysis of all the published cases of other practitioners; so that the book is as complete as it was possible to make it.

Its publication is an ample proof of the useful work that has been done at the Hospital for Diseases of the Throat, without which institution it could not have been written. While we commend the author for the diligence with which he has compiled the cases of others, it is his own which constitute a valuable contribution to science, and to them, therefore, we must chiefly look. This work will certainly at once take its place as the author's chief one, and on it alone he may be content to let his reputation rest. Before passing to particulars we would remark that it is well got-up and profusely illustrated. In regard to the latter point we must not forget to say that the chromo-lithographs and wood engravings are alike the product of Mr. Lennox Browne, who unites the skill of the artist and laryngoscopist, and has thereby been able to take from nature representations of disease, the fidelity and finish of which have never been exceeded.

The work before us, we are told, is based on 150 cases, the majority of which we suppose were seen at the Hospital for Diseases of the Throat. It contains detailed reports of 112 of the cases, of which 86 have not before been published; but of these 100 were treated—12 having merely been observed, 77 were cured, 18 improved, 3 remained unbenefited, and 2 died. When we remember what the course of such cases would probably have been before the laryngoscope was introduced, we hesitate not to say that the result is a grand triumph for our art.

The work is very methodically arranged and the references are numerous. It is a good sign when a busy practitioner, who might easily have gained much credit for the story of his own experience, imposes on himself the duty of careful research. We have taken the trouble to follow him in some cases to his references, and can say they have been accurate, and we have also gone through his work with great care, comparing it with our own rather extended experience, and shall, therefore, ask the reader to accompany us in a brief retrospect.

The author opens with a definition of benign growths in the larynx, which alone are his subject, malignant

having been, intentionally, excluded. This definition is, "New formations of benign character, forming projections on the mucous membrane of the larynx, generally giving rise to aphonia or dysphonia, often to dyspnoea, and occasionally to dysphagia." This leaves the reader in no doubt as to what the author means to include in his book, and, to make us still further safe, he adds the many synonyms under which these laryngeal growths are known. Then comes the history, which forms Section I. of the book, carefully traced from the time when, more than a century ago, Koderik operated on a growth through the mouth, but about which we may justifiably feel much doubt, as we know very little about it. Indeed, the few exceptions, brilliant as they were, in which diagnosis was made and treatment resorted to before our own times, have but little interest for us now, though they certainly do testify to the zeal and skill with which our predecessors practised the Profession, and some of them forestalled by genius the discoveries they were not destined to have for their assistance. Section II. is devoted to "Causes," of which the most important is chronic congestion. Indeed, it is not improbable, as believed before laryngoscopic days, that all causes of polypus in the larynx act by setting up hyperæmia. Age has been estimated differently by various writers. In the author's experience middle life has been the most common age, though we are not quite sure that the statistics of unpublished cases by other leading practitioners would not very greatly modify this result. We find of these 100 cases that only 2 occurred under five years of age, 4 between that and ten, and 4 more in the next five years. From fifteen to twenty only 2. Between twenty and forty there were 43 cases, and from that to fifty there were 28 more. We happen to know of some cases that, causing death in children, were put down as croup, and we have no doubt that this and other names do frequent duty in the Registrar-General's returns—even as must have been the case before the laryngoscope was invented. *People who use their voice out of doors* are, according to the hospital statistics, the most liable to growths in the larynx. Hawkers, criers, singers, &c., are mentioned under these occupations. We pass on to Section III., which is on "Symptoms." The author divides them into functional and physical, after Cavsit, having given up the division into subjective and objective.

We have only to remark on the latter that though the laryngoscope is most important, other points are not omitted, such as the laryngeal sound, digital exploration, forcible external elevation of the larynx combined with depression of the tongue, auscultation and percussion of the thorax, examination of the sputa, &c. All these, as well as constitutional symptoms are certainly worthy of a thought, even though we can now see the growths. We may mention that cough was not as a rule troublesome, and pain was almost never complained of; but dyspnoea was present in nearly a third of the cases, and these statements almost exactly correspond with our own experience. Dyspnoea is often paroxysmal, and our author observes that this is partly accounted for by the patient sometimes getting into an unusual position. We think, however, it may be admitted that any cause of dyspnoea situated in the larynx is liable to give rise to paroxysms more frequently and to a greater extent than causes located elsewhere. Again, dyspnoea from any cause is likely to be worse at night, and there are many other points about this symptom that make it, in every disease, worthy of attentive study. In laryngeal cases inspiration is mostly more difficult than expiration, but in a few cases the reverse difficulty is very marked.

Dysphagia is not often present. When it is the epiglottis is mostly the seat of the disease.

This brings us to consider the position of these growths. In the author's 100 cases both vocal cords were involved in 27, the right vocal cord in 25, the left in 15. In the cases collected from other authors, the vocal cords were alone affected in 61.4 per cent. It will thus be seen that

\* "Growths in the Larynx." By Morell Mackenzie, M.D., Physician to the Hospital for Diseases of the Throat, &c. London: J. and A. Churchill, 1871.

the cords are more liable than other portions of the larynx to be the seat of growths.

As to the laryngoscopic appearances of growths, our author very judiciously describes them according to their pathological nature, classifying them as papillomata, benign epithelial growths, fibromata, fibro-cellular growths, myxomata, lipomata, fasciculated sarcomata, cystic growths, adenomata and angeiomata. The appearances in each case are pointed out, and, further on, the several pathological varieties occupy a chapter which we must pass over.

We next come upon an account of the various laryngeal sounds and the methods of examination—very precise and exact; and then Section IV. is devoted to "Diagnosis." This is, of course, of the highest importance, and might, perhaps, have been more thoroughly exhausted, inasmuch as what is easy to our author is very difficult to those who have little laryngoscopic practice. We note this because we have known mistakes to occur to practitioners most desirous of benefiting their patients. Thus, syphilitic condylomata disappear rapidly under judicious treatment, and will often do so without medical aid, and yet they occasionally resemble other non-specific growths to a degree that would tempt any one, not familiar with them, to local treatment which would be injurious. Two cases lately came under our notice, in which gentlemen, who had given some attention to the matter, were thus thinking of operating, when the disappearance of the condylomata under iodide of potassium, adopted at our suggestion, showed their nature. So of false excrescences and malignant growths. Although the expert laryngoscopist may be sure, we would caution those of our brethren, who do not pretend to be such, to make assurance doubly sure in this matter of diagnosis. We believe that our author will, on this point, endorse our warning, even though his own experience may seem to him to make the diagnosis so easy.

Prognosis occupies but three pages, and we pass on to Section VII., devoted to the all-important question of "Treatment." Here, again, we would utter our warning. Simple as in some respects the treatment of such cases may be, we trust that every one who proposes to undertake it, will take every care to qualify himself for the onerous duty.

Diagnosis and prognosis require certain qualifications, but treatment needs others in addition. The conduct of such cases requires the judgment of the physician and the skill of the surgeon, associated with patience, prudence, a readiness for emergencies, and a contempt for mere display that not every one possesses. We do think that every one should perfect himself in laryngoscopic methods before he attempts the removal of a growth.

In some cases we are glad to find our author recognises the propriety of non-interference. There are a considerable number of benign growths in which the inconvenience is so slight that it is wiser to bear with it. Still in a very large number active measures must be adopted, and the question is what shall be done?

The first mode considered is removal by operation, *per vias naturales*. This is the triumph of laryngoscopy, and when it can be successfully accomplished the patient may fairly be said to have been cured. Occasionally a single operation may suffice, but almost always the growth has to be removed in pieces at several sittings. But this is to the opening of the larynx what lithotomy is to lithotomy. Sometimes chemical treatment may be applied locally, and we are half inclined to fancy that more may be attained in this way than has hitherto been attempted. This is described in the book before us, but the palm seems to be given to operative procedure, and the many instruments that have been used for this purpose are described and figured. We cannot enter into a comparative estimate of these, but we may say that we have had resort on various occasions to all, and we think all have their merits; while, in the majority of cases, we think most practitioners will be glad to avail themselves of more than one. In fact, our own practice affords us

little opportunity of estimating their value, as we have never hesitated to avail ourselves of several modes in any given case. We have at the same time great respect for the maxim "it is a bad workman that finds fault with his tools," and have sometimes been unusually successful with instruments that we had at hand, but to which we should have preferred others.

We are gratified to find that the author thinks the laryngoscopic method is to be preferred, whenever practicable, to incision from without, which if a more showy is a much more dangerous procedure. Indeed, except in children and a few very exceptional cases, we doubt if it be justifiable. Out of 28 recorded cases of division of the thyroid cartilages 9 ended fatally. Division of the thyro-hyoid membrane is not so dangerous, but then cases adapted for this operation are more likely to be removable by the laryngoscopic methods through the mouth.

Tracheotomy is a more grave operation than any, and would not, we presume, be resorted to without carefully weighing all the chances. At the same time we should regret to say a word that might induce any one to hesitate to act as soon as tracheotomy becomes necessary. No one, in fact, should undertake any laryngeal operation who is not prepared to perform tracheotomy should the necessity for it suddenly arise. Lastly, we may name that the two modes have been combined, but that this is seldom needed is seen in the fact that our author has only resorted to this double procedure on two occasions.

We have now only to speak of the cases. First, the author's own, 100 in number, are reported in detail, and then their chief features presented in tabular form. Alone they constitute a clinical study of the very highest value, of which it is impossible for us to present an abridgment. All interested in the subject ought to ponder every case.

Lastly, the cases of others have been collected from the journals with praiseworthy industry, and give a *coup d'œil* of all that has been achieved in this fruitful field of practice.

## Correspondence.

### IDENTITY OF SCARLATINA AND FOOT AND MOUTH DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I ask the insertion of the following in your next publication. I wish to get the opinions of my medical brethren as to the views I entertain on the identity of scarlet fever and the foot and mouth disease in cattle. I am convinced they are the same for the following reasons:—

Scarlatina has never been, in my remembrance, after thirty years' experience, so long prevalent as an epidemic, and the disease in cattle has never been more serious and general than at present. The great prostration, the pains in the limbs, fever, &c.; mouth and throat affected, and sequently, symptoms similar to those of dropsy, rheumatism, &c., in the human subject leaves no doubt on my mind as to their being one and the same disease. I have asked the opinions of some large stock-holders in this neighbourhood, and they have informed me that cattle having once been attacked by the disease are almost free from subsequent attacks, and, in case it should again appear amongst them, it is always in a very mild and modified form, as is the case in a second attack of scarlet fever in mankind.

May I ask my medical brethren to give me their opinions as early as possible on this subject, and that those who may coincide in my views may make trial by vaccination from cows, heifers, &c., on children before the present outbreak of disease in cattle passes away, as I believe it can do no harm, and may be the means of conferring on the human race a benefit similar to Jenner's discovery of vaccination of cow-pock. I may state that it is my intention, in case I receive favourable views from my professional brethren, to try the experiment on some of my own children who have not had scarlatina, as I have lost my eldest two girls from that disease.

Yours faithfully,

Belmont, Navan.

P. J. NICOLLS, M.D.

P.S.—I shall expect early replies from my medical friends

## THE CONTRADICTIONS OF DR. JOHNSON'S THEORY OF TREATMENT IN CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am surprised at Dr. Johnson's statements read before the Medical Section at the annual meeting of the British Medical Association in Plymouth, August, 1871, concerning the treatment of cholera, and more especially at their corroboration in Watson's revised "Lectures on Medicine." I cannot resist placing in juxtaposition a few of these assertions appending an occasional annotation of my own, and shall feel greatly obliged should you deem them worthy of insertion in your out-spoken Journal. Without doubting the duty of the physician to regulate the amount of fluid discharged, and the value of the evacuant practice at the commencement of relaxation of the bowels, I must call in question the decided *velo* placed upon astringent remedies, until the poison had either evacuated itself or destroyed the patient.

I am, Sir, your most obedient servant,

R. HANSLIP SERS, M.R.C.S.E.

The greatly diminished, almost suspended secretion of bile and urinary solids during collapse is explained by the *defective circulation*, and the consequent diminished oxidation of blood and tissues.

Opiates in the early stages of diarrhoea and cholera would be more frequently and decidedly injurious, were it not for the fact that their absorption is prevented by the *rapid current* of liquid which is being poured from the *blood* into the alimentary canal; therefore they are quickly expelled, together with the morbid secretions, and they are powerless to arrest the discharges.

There is one remedy which is almost universally applicable in all forms and stages of the disease, and that is an abundant supply of cold water to flush the intestinal sewer, and to wash out the poisonous discharges. A copious imbibition of pure cold water will suffice for the cure of most curable cases.

The marvellous temporary relief which follows the injection of a warm saline solution into the veins during collapse is due partly to the morbid blood being diluted, and thereby rendered less obnoxious to the resisting arterioles, but mainly to the relaxation of the arterial spasm by the high temperature of the injected liquid. It has been found by those who have had most experience of this method of treatment, that hot injections are more efficacious than those of a lower temperature.

In the treatment of cholera and choleraic diarrhoea, which is, in fact, cholera in a mild form, the main principle to bear in mind is, that the discharges are as es-

These remarks are placed side by side for obvious reasons. The italics are my own. Opium stated to be powerless, nevertheless might it not possibly relax the arterioles relieve pain (itself a constant source of extreme nervous exhaustion), and above all, restrain undue peristaltic action of the bowels, opium is, in my experience, a valuable *preventive* of *collapse*.

This is contradictory. Why not warm water much for the same reasons as those given in advocacy of opium.

Had the learned professor given measles instead of small-pox, one might have accepted the theorem. Unfortunately in small-pox and scarlatina, the less rash the better,

essentially curative as is the eruption of small-pox.

Palpation and percussion of the abdomen reveal the fact that there occurs not unfrequently a painful and sometimes a paralyzing over-distension of the bowel by rapidly effused morbid secretion. This, if not promptly relieved, may even go to the extent of forming a fatal obstruction. More especially is this likely to happen when the sensibility of the bowel has been deadened by opium. The plan to prevent and to remove this accumulation is to give some quickly acting yet unirritating evacuant dose. For this purpose, castor-oil is, on the whole, better suited than any other remedy.

The objection sometimes raised—that all remedies must be useless, because none are absorbed—obviously does not apply to such a remedy as castor-oil, which, by its merely local action upon the mucous surface, stimulates the bowel to expel its contents.

The time to give opium, if at all, is in small doses to soothe the bowel after the expulsion of the poisonous secretions. Opiates are useless, and even dangerous, when the blood is poisoned, or when the bowel contains offensive morbid secretions.

otherwise a confluent small-pox would be the favourable form, and the greater the extent of the efflorescence of scarlatina, the more agreeable the prognosis. As a matter of course in either case, there must not be actual suppression of the eruption.

Opium "is powerless to arrest the discharges."

The bowels already over-distended with fluid are to be further charged, in order to produce a flush. May not the elastic bowels yield to the pressure, instead of exerting extra propelling force to expel the choleraic poison?

Is it true? or is it not true? that castor-oil is quickly evacuated either upwards or downwards. May not the oedematous bowels flooded with the rapid choleraic effusions effectually interfere with its local action. Is castor-oil any better than olive-oil?

The Practitioner may, under a condition prescribe opium—mark—after the expulsion of the poisonous secretions. In other words, when the patient is convalescent. I should be inclined to try in cholera, wet packings saturated with a weak solution of Condy's fluid, or of carbolic acid—the free internal administration of disinfectants, and frequent warm enemata containing beef-tea, milk, yolk of egg, gelatine, &c.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I fully agree with Dr. Lane in his proposal thrown out in the last number of the MEDICAL PRESS to establish a fund for the widows of medical men throughout England. I hope the "Faculty" will rouse themselves from their long years of lethargy on this important subject to the healthy action of up and doing, which, if accomplished, would not only be an advance on the past, but a very great boon to the recipients of it.

This society should extend to Ireland and Scotland, as under one common fund, and I am sure every man with the impress of Hippocrates on his brow, over the United Kingdom, will be only too glad to send in his subscription for an object so laudable and philanthropic in its nature.

I remain, yours truly,

DANIEL HEAGERTY, L.R.C.S., &c.,  
Medical Officer of Bellingham Union.

## Foreign Medical Literature.

ON

### PUBLIC DRUNKENNESS AND ALCOHOLISM

FROM THE

### POINT OF VIEW OF LEGAL REPRESSION.

BY DR. THEOPHILE ROUSSELL,  
Deputy to the French National Assembly.

(Translated from the *Courrier Médical*, by A. VICKERY.)

THE consideration of the text of former legislative enactments proves that the pathological and social consequences of alcoholic drunkenness were not even suspected. From the Bible up to the celebrated edicts of the Emperor Maximilian in 1550, of Charles V. in 1531, of Francis I. in 1536, legislators have given only as reasons for the most rigorous measures, the offence to God, blaspheming, the anger, the oaths, the blows, the violence, the attacks of fury and crimes which follow drunkenness.

Moralists and theologians have remarked as consequences of drunkenness the loss of habits, of work, and order, the abandonment of the family and the domestic affections, misery and its train of evils, vices, and criminal solicitations. But there is a character scarcely noticed by ancient observers, and which becomes more and more marked in the progress of alcohol in popular consumption, this is the pathological character which has earned for drunkenness the name of *intoxication* in the English language; and it is only in our epoch that observation and medical statistics have revealed the fatal effects of alcoholism on the family of the drunkard, and its dangers for the future of entire populations.

It is to medicine that it belongs to establish well for legislators this fact, which they have not yet been in a position to appreciate well, the commencement of this distinction between drunkenness properly so-called and this new alcoholic drunkenness which made its first appearance in science in 1813 by the "delirium tremens," and of which the well-known writings of the physicians of the Slavonian, Scandinavian, and Germanic nations have since revealed to us the many forms and frightful developments.

In this new case we see alcohol absorbed with a taste which quickly becomes irresistible, affecting powerfully the organism, altering soon its radical forces, destroying little by little the individual physique, degrading more and more the moral character, attacking in its course not only the individual, but also his descendants, bequeathing thus to families, by a fatal inheritance, debility, epilepsy, deafness, dumbness, a crowd of nervous disorders, and to the moral character imbecility, idiocy, mental alienation, idleness, and violent and perverse instincts.

It is important that the legislature should know that this terrible series of evils, unknown to the ancients, can

be passed over entirely by an individual without any manifestation, offering the decided character of drunkenness properly so-called. And this capital point, which medicine alone can throw light upon, suffices to show how the limits in which the propositions of law, submitted at this time to the National Assembly, are comprised, are out of proportion with the real extent of the question which it is intended to resolve, if it is true that it behoves us to diminish the evils which the abuse of alcoholic liquors causes to day in society.

The progressive manifestation of these evils has struck the attention of physicians and governments from the first in northern countries and the Germanic States, where they have followed, as everywhere, the progress of the new industry of the distilleries, which tends to substitute for the consumption of fermented liquors, and even of the brandy of wine, liquors still more alcoholic obtained by the distillation of grains and fruits.

The author traces the march and progress of alcoholism in the Slavonian countries, in England, Germany, the Scandinavian countries, the New World, &c.; since it becomes necessary to know the means of repression directed, in the various countries, against the growing abuse of alcoholic liquors, *furor bibendi*.

He establishes from statistics the special developments of alcoholism and of its ravages in France; and, after having insisted on the insufficiency of actual legislation in that which concerns drunkenness, he continues in these terms:—"I have endeavoured, by a glance over the world and over history, to establish that alcohol acts everywhere as a destructive poison of frightful power on populations which are abandoned to it, without any support in their manners or any bridle in their laws; that the slight efficacy of ancient laws has been due to the excess of their rigour, to the opposition which they encountered in the customs, and to the lesser gravity of the evil against which they were directed; and, lastly, that preventive and repressive measures have produced an incontestable benefit everywhere when they have been wisely combined and applied, after consideration of the circumstances and probable results, and particularly where the spirit of association and individual initiative have lent to it their powerful concurrence."

What arguments is it yet necessary to seek to show that alcoholic drunkenness has now gone beyond the competency of the police and the local powers? and that the repression of this scourge can only be effected by a vigorous effort of society promoting and sustaining the action of a good law.

The law called for at this time by the interests of society ought, if I mistake not, to rest on a triple base. 1st. Combined action of various preventive means, of which I have proposed the programme in commencing; 2nd. The employment of repressive measures graduated against drunkenness, its relapses, and habitual drunkenness. 3rd. Means for the protection of the interests of the family and of society against the effects of the intellectual and moral perversion produced by alcohol among the individuals who make an abuse of it.

In accepting, as demonstrated, the necessity and utility of penal repression, we arrive at this first conclusion:—the necessity of defining public drunkenness as a correctional offence. Our penal code makes no mention of drunkenness. It cannot know it in effect, since it exists not as a judicial fact, it is only a simple fact.

This fact can only draw attention to the public morals and social interests. It has none the less remained up to this time foreign to our legislation.

The necessary consequence of the juridical definition of drunkenness as a correctional offence, is to call the penalties correctional, and to inflict, for the first time, a minimum fine of sixteen francs.

The fact of drunkenness when it is fortuitous, foreign to the will and the habits, or even the result of a first imprudence, seems to merit so much indulgence that the fine in a simple police matter, which has a minimum of

one franc and a maximum of fifteen francs, would seem a sufficient penalty.

If we take into consideration two dominant points in this question: that of the pathological effects of drunkenness, above all of alcoholic drunkenness, and that of the social consequences of drunkenness, we recognise that the fact of relapses is of major importance in repression.

This graduation of penalties is to be found in the edict of Francis I., and in the recently improved laws of foreign countries, and it is indispensable to apply this wise principle, and to endeavour to obtain from its use all its salutary effects. The first relapse would appear to be sufficiently punished by doubling the fine (from 25 to 50 francs). At the second only it might appear desirable to add to this fine correctional imprisonment of from six to twelve days.

## Medical News.

**University of Cambridge.**—The late agitation and legislation, having for their object the admission of Dissenters from the Established Church to the prizes of the Universities, has just received an exemplification at Cambridge. At Trinity College, yesterday, Dr. Michael Foster, well-known in connection with the Liberation Society, a member of the London University, and Mr. Hopkinson, Senior Wrangler, and First Smith's Mathematical Prizeman at Cambridge in 1871, were amongst those elected Fellows of Trinity College. Neither of these gentlemen are members of the Church of England. Dr. Foster was not, of course, originally a member of Trinity, but having been elected Prælector in Physiology, has now been elected Fellow Honorary Causa.

**Hydrophobia.**—At an inquest held in Manchester on Saturday, upon the body of a woman who had died from hydrophobia, it was stated that the ordinary remedies failed, and the only drugs which gave her relief were morphia and chloroform.

A donation of £30,000 has just been made to the Royal Albert Asylum for Idiots, Lancaster, by Mrs. Brooke, in accordance with the wishes of her late husband, the Rev. Richard Brooke, of Selby.

The Cancer Hospital, Brompton, has received a third donation of £1,000 from G. M. E.

**Life in Persia.**—A letter, dated Teheran, Aug. 7, in the *Cologne Gazette*, states that cholera, pestilence, famine, and bad government make the situation in Persia more horrible from day to day. Of the 120,000 inhabitants of Meschad, the capital of Chorassan, two-thirds perished from hunger and disease in July last, while the remaining third fled, and were mostly captured by roving troops of Turkomans and Afghans, and led into slavery. At Chiras and at Tabris insurrections have broken out. The cholera declared itself at the latter place—which suffered also terribly from an inundation—and on the Turkish frontier at Solimanich cases of pestilence have occurred. The Government has refused the help offered by Russia and England. The inhabitants of the capital, knowing that a petition to the Shah would remain without answer, addressed themselves to the foreign representatives, who declined to intervene. When, at the beginning of August, the Shah returned to his capital, he was received before the gates by thousands of howling women, who were afterwards dispersed by the police. The Shah took up his residence in a neighbouring castle, and issued a decree ordering the sale of bread at a nominal price. No bread came forth, and the Shah then ordered, as remedial measures, to put into chains the vizier of the town, to slit open the belly of the chief baker, to put several other bakers into their ovens. The émeute was thereby put down, but not the prevailing misery, and a terrible catastrophe is expected.

**Careless Surgery.**—The *Wanderer* of Vienna relates the following story:—"The Burgomaster of Storaeczynetz, in the Bukovina, was recently attacked by a bull and received a severe wound in the region of the heart. A surgeon was summoned, who dressed the wound, immediately after doing which he discovered that a gold ring had disappeared from his finger, and, as he believed, had been left in the wound. It would

have been dangerous to reopen the wound, and therefore no attempt was made to remove the ring. The burgomaster, however, died a day or two afterwards, and a charge was made against the surgeon by another medical man who had been in consultation with him, and who declared that the deceased had died, not from the effects of the wound, but from inflammation produced by the presence of the ring in question. The surgeon is to be tried for unskilful treatment, and the body of the burgomaster is to be exhumed for the purpose of ascertaining the exact cause of death.

**Extraordinary Charitable Bequests.**—The following legacies appear in the will of Mrs. C. E. Walmesley, 34 Connaught square, Hyde park, all to be paid (free of duty) within six calendar months after testatrix's decease, which event took place on the 13th ult.:—£1,000 each: London, Middlesex Royal Free, University College, and St. Mary's Hospitals. £500 each: Great Northern, Metropolitan Free, and British Lying-in Hospitals. £300 each: London Fever Hospital, National Hospital for the Paralysed and Epileptic, Royal National Lifeboat Institution, Royal Society for Protection of Life from Fire, and Royal Society for Prevention of Cruelty to Animals. £200 each: Westminster, Charing-cross, and King's College Hospitals; City of London Hospital for Diseases of the Chest, Samaritan Free Hospital, Royal Hospital for Incurables, British Home for Incurables, City Orthopedic Hospital, Royal Sea Bathing Infirmary, Metropolitan Convalescent Institution, Asylum for Idiots (Earlswood), Lock Hospital Asylum, London Female Penitentiary, Cripples' Home and Female Refuge, Indigent Blind Visiting Society, and British Asylum for Deaf and Dumb Females. £100 each: Seamen's Hospital Society (Dreadnought), Hospital for Women (Soho square), Royal Westminster Ophthalmic Hospital, Royal Orthopedic Hospital, Western General Hospital (Marylebone road), Albert Orphan Asylum, British Orphan Asylum, London Orphan Asylum, Infant Orphan Asylum, Asylum for Fatherless Children, National Orphan Home, Cancer Hospital, (London and Brompton). House of Charity for Distressed Persons, Royal Infirmary for Diseases of Children and Women, Queen Charlotte's Lying-in Hospital, City of London Lying-in Hospital, Royal Medical Benevolent College Fund, and Association for Promoting General Welfare of the Blind. £50 each: Dental Hospital of London, Infant Home (Great Coram street), West London Hospital (Hammersmith), Central London Ophthalmic Hospital, (Gray's inn road), North London Consumption Hospital, Royal London Ophthalmic Hospital, General Lying-in Hospital (Lambeth), Infirmary for Consumption and Diseases of the Chest, Small-pox and Vaccination Hospital, Hospital for Sick Children (Great Ormond street), St. Mark's Hospital (City road), City of London and East London Dispensary. £25 each: Western Ophthalmic Hospital (Marylebone road), Seaside Convalescent Hospital (Seaford), Invalid Asylum (Stoke Newington), and Home for Convalescent Children (Mitcham), besides thirty-one legacies to other societies and institutions, non-medical.—*Illustrated London News.*

**GRAEVES.**—On the 1st inst., **A. G. Greaves, M.R.C.S.E.,** of Derby, aged 59.  
**GRAVES.**—On the 7th inst., at Westbourne Park, Bayswater, **Emma Spencer,** the beloved wife of **J. S. Graves, Deputy Inspector General of Hospitals.**  
**HIGGINS.**—On the 14th inst., at Kensington, **J. R. Higgins, M.R.C.S.**

**THE ROYAL HOSPITAL for DISEASES of the CHEST,** City road.—Founded A.D. 1814.

Under the direct patronage of Her Majesty the QUEEN.

Notice is hereby given that the Council will meet in the Board Room of the Hospital, on Tuesday, the 7th day of November next, at half-past 4 o'clock p.m., to receive and examine APPLICATIONS from candidates for the OFFICE of (OPERATING) SURGEON to the Hospital, vice **Mr. Francis Mason, F.R.C.S.,** resigned. Candidates for this office must be Fellows or Members of the Royal College of Surgeons of England not practising midwifery or pharmacy.

Any further information may be obtained on application to the Secretary or Resident Medical Officer, personally or by letter.

Letters on application, addressed to the Council, with testimonials, to be sent to the Hospital, directed to the undersigned, before the time above-mentioned.

The election will be held at a Special General Court of Governors on Tuesday, November 21, the names of candidates approved by the Council being previously announced.

**CHARLES L. KEMP,** Secretary to the Council.

City road, Oct. 10, 1871.

## THE ADELAIDE HOSPITAL, PETER STREET, DUBLIN.

**Physicians**—**Henry H. Head, M.D., M.R.I.A.,** Fellow of the College of Physicians, **James Little, M.D., M.R.I.A.,** Fellow of the College of Physicians, Lecturer on the Practice of Medicine in the Ledwich School of Medicine.

**Surgeons**—**Albert J. Walsh, M.D.,** President Royal College of Surgeons, **John K. Barton, M.D.,** Fellow Royal College of Surgeons, Lecturer on Surgery in the Ledwich School of Medicine, **Benjamin Wills Richardson,** Fellow and Member of the Court of Examiners, Royal College of Surgeons.

**Obstetric Physician**—**Lombe Atthill, M.D.,** Fellow and Examiner in Midwifery, College of Physicians.

**Ophthalmic Surgeon**—**H. Rosborough Swanzy, M.B., L.R.C.S.I.,** lately Assistant at Professor von Graefe's Ophthalmic Hospital, Berlin.

**Assistant-Physician**—**Walter G. Smith, M.D.,** Fellow and Censor College of Physicians, Senior Demonstrator in the University School.

**Assistant-Surgeon**—**Montgomery A. Ward, M.B., M.Ch., L.R.C.S.I.,** Demonstrator of Anatomy, Ledwich School of Medicine, Ex-Medical Scholar, T.C.D.

The central position of this Hospital renders it peculiarly convenient to gentlemen attending Lectures at the University, College of Surgeons, or Ledwich School.

The arrangements for Clinical Teaching have been made as complete as possible, and are such as not to interfere with attendance at the Medical Schools.

There are Fever Wards apart from the Hospital, and two Wards for Infants and Children.

Special hours are devoted to Clinical Instruction in the Diseases peculiar to Women, the Diseases of the Eye, and Cutaneous Diseases, and Students are individually instructed in the Use of the Stethoscope, Ophthalmoscope, Laryngoscope, and Microscope.

Two Resident Pupils are selected half-yearly.

Prize Examinations are held at the termination of the Session.

Further particulars can be obtained from **Dr. Atthill, 11 Upper Merion street,** or any other Member of the Medical Staff.

Established 1848.

## PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

**J. BAXTER LANGLEY LL.D. M.R.C.S., F.L.S.,**

&c., (KING'S COLL.), and Author of *VIA MEDICA*,

Has always upon his books a large number of desirable investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays, from 11 till 2.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for negotiation (in addition to those advertised in *Dr. Langley's List*, (which is sent post free on application).

**Y 318.** In a **WESTERN COUNTY**, a very desirable **PRACTICE** for transfer. The income is £600 a year, and there is only one opponent, although there are about 2,100 residents in the immediate locality. Transferable Appointments yield £100 a year. Six months' introduction. Only one horse required. The residence is an excellent family-house, with stabling, coach-house, and capital garden. Part of the premium may be paid by instalments.

**Y 317.** **MIDLAND.**—Receipts upwards of £800 a year, including valuable Appointments yielding £220 a year, No resident opponent within two miles. Patients good middle-class. Efficient introduction.

**Y 316.** **PARTNERSHIP** without premium, A Practitioner, resident in a pleasant Southern County, is willing to take a Partner for the third share of his Practice, with conditions for purchase of further shares at future date depending upon success. Present income £600 a year, with prospects of considerable increase. No Gentleman need apply who has not at command a sufficient sum to furnish a small house.

**Y 262.** In a **CHARMING AGRICULTURAL DISTRICT**, where there are numerous wealthy residents, a well-established **PRACTICE** for Transfer. The receipts average about £500 a year, with no Appointments, except two small clubs at good rates. Very little night work, and no midwifery under £2 2s. The work is light and pleasant, the average visiting fee being 7s. The house is vendor's freehold, and could be let at £35, or sold if desired; it contains eight rooms; pleasant garden, with detached coach-house, stabling, &c. Two horses are kept, but one is sufficient for the Practice, and no assistant is required. There is scope for considerable increase.

TECHNICAL EDUCATION.  
SCIENCE AND ART DEPARTMENT.  
**ROYAL COLLEGE OF SCIENCE FOR IRELAND.**  
STEPHEN'S GREEN, DUBLIN.  
SESSION—1871-72.

This College supplies, as far as practicable, a complete Course of Instruction in Science applicable to the Industrial Arts, especially those which may be classed broadly under the heads of CHEMICAL MANUFACTURES, MINING, ENGINEERING, and AGRICULTURE.

A Diploma of Associate of the College is granted at the end of the Three Years' Course.

There are Four Royal Scholarships, of the value of £50 each, yearly, with Free Education, including Laboratory Instruction, tenable for two years. Two become Vacant each year. They are given to Students who have been a year in the College. There are also Nine Exhibitions attached to the College of £50 each, with Free Education and Laboratory Instruction, tenable for three years. Three become vacant each year. These are awarded at the Annual May Examinations of the Science and Art Department.

The Fees are £2 for each Course, or £10 for all the Courses of each year, with the exception of Laboratory.

The Laboratory Fee is £12 for the full Course of Nine Months, or £2 per month.

**SUBJECTS OF INSTRUCTION.**

Applied Mathematics, Mechanism and Machinery, Descriptive Geometry, Geometrical, Mechanical and Engineering Drawing, Experimental Physics, Chemistry (Theoretical and Practical), Botany, Zoology, Geology, and Palaeontology, Mining, Surveying, Agriculture.

The Laboratory is open for Instruction in Practical Chemistry, Metallurgy, and Assaying, from 10 to 4 o'clock every Week-day during the Session, except Saturdays and Holidays.

The Session commences on MONDAY, OCTOBER 2.

Programmes may be had on application to the Secretary, Royal College of Science, Stephen's green, Dublin.

FREDERICK J. SIDNEY, LL.D., Secretary.

**THE WESTMORELAND LOCK HOSPITAL**  
FOR THE TREATMENT OF VENEREAL DISEASE,  
TOWNSEND STREET.

**SURGEONS TO THE HOSPITAL.**

Benjamin McDowell, M.B.T.C.D., L.K.Q.C.P.I., L.R.C.S.I., Professor of Materia Medica in the Ledwich School of Medicine, &c., Surgeon to Mercer's Hospital.

John Morgan, A.M., T.C.D., L. and F.R.C.S.I., Professor of Practical Anatomy (Surgical and Descriptive) Royal College of Surgeons, School of Surgery, and Surgeon to Mercer's Hospital.

THE HOSPITAL contains 150 Beds; 674 patients were admitted during the past year suffering from every variety of Venereal Affection, thus affording ample opportunity of studying the disease in all its forms.

The wards are visited daily between twelve and two o'clock, so as not to interfere with attendance at general hospital practice.

Two Clinical Lectures will be delivered each week, commencing the first Monday in November.

Fee for Hospital attendance, including Clinical Lectures;—For Winter Session, six months, £4 4s.; for the Summer Session, three months, £2 2s.

For further particulars apply to Dr. McDOWELL, 29 York street; or Mr. MOROAN, 23 Stephen's green North, or at the Hospital.

**THE LEDWICH SCHOOL OF SURGERY.**  
PETER STREET.

The Lectures are to be delivered by the following Teachers, who are responsible for the general discipline and instruction of the Class:—

|                                       |  |

All the several Courses of Lectures required by the various Licensing Bodies to entitle the Student to present himself for Examination are delivered in the Theatre of the Institution, and are fully recognised.

The School is in a central situation, and in the immediate vicinity of, and in direct connection by means of its Teachers, with four great Medical and Surgical Hospitals, thus affording to the Student the most ample opportunity of acquiring a thorough knowledge of the symptoms and treatment of disease. Demonstrators will be present in the Dissecting-room at all hours, in order to afford that assistance which is always so essential to the beginner in his first attempts to acquire a knowledge of Anatomy.

At the termination of the Session Prizes will be awarded to the best Answerers in each Department. EDWARD LEDWICH, Secretary.

**MERCER'S HOSPITAL,**  
WILLIAM STREET, DUBLIN.

WINTER SESSION—1871-72.

Visited punctually at Nine a.m. each Day.

Physicians—Thomas P. Mason, M.B. Lond., F.R.C.S.I., Lecturer on Anatomy and Physiology in the Ledwich School of Medicine; Henry Eames, A.B., M.B. T.C.D., L.K. & Q.C.P.I., Lecturer on Practice of Medicine.

Surgeons—Edward Ledwich, F.R.C.S.I., Lecturer on Physiology and Surgical Anatomy in the Ledwich School of Medicine, Member of Council Royal College of Surgeons in Ireland, &c.; Edward S. O'Grady, M.R.I.A., Ch.M., M.B., A.B. Univ. Dub., F.R.C.S.I., Q.C.P.I., Member of the Court of Examiners Royal College of Surgeons, Ireland; John Morgan, A.M. T.C.D., F.R.C.S.I., Professor of Surgical and Descriptive Anatomy Royal College of Surgeons, Ireland, Surgeon to the Westmoreland Lock Hospital, Member of Council R.C.S.I., &c.; Benjamin F. McDowell, A.B., M.B. T.C.D., L.R.C.S.I., Surgeon to the Westmoreland Lock Hospital, and Lecturer on Materia Medica in the Ledwich School.

THIS HOSPITAL, situated in the centre of this Metropolis, and in the midst of a densely-crowded population, has its doors constantly open at all hours for the reception of cases requiring prompt and energetic treatment. Two new wards for the reception of Fever and Contagious Diseases, are now open in addition to the previous accommodation of the Hospital, while its Chronic Wards are filled with patients from the Dispensary which is daily held for the relief of a numerous class, to whom advice and medicine are supplied gratuitously.

Systematic Clinical Lectures and catechetical instruction will be employed for the purpose of conveying information to the Class.

The appointment of Resident Pupil is open to any Student through the medium of a Competitive Examination, and at the termination of his office he will be entitled to a Special Certificate, should his conduct have met with the approval of the Physicians and Surgeons.

In all cases where it is possible, due notice will be given of every capital operation, so as to ensure the attendance of the Student.

The Hospital stands in the immediate vicinity of four of the principal Medical Schools, and is recognised by all Licensing Bodies.

Terms of Attendance.—Six months, Six Guineas; Nine months, Eight Guineas; Perpetual Pupils, £21.

Further information can be obtained from any of the Physicians or Surgeons of the Hospital, or from the Registrar.

By order,

September. 1871. JAMES SHAW, Registrar, Mercer's Hospital.

**MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.**

Physicians: William Stokes, M.D., Physician in Ordinary to the Queen in Ireland, Regius Professor of Physic, University of Dublin; Arthur Wynne Foot, M.D., Univ. Dublin, F.K.Q.C.P.I.

Surgeons: George H. Porter, M.D., University of Dublin, F.R.C.S.I., Surgeon in Ordinary to the Queen in Ireland, Surgeon to Stinson's Hospital, Consulting Surgeon, Coombe Lying-in Hospital.

James H. Wharton, A.M., M.B., University of Dublin President, F.R.C.S.I., Senior Lecturer on Surgery at the Ledwich School of Medicine; Surgeon to Cork street Fever Hospital, and to the Hospital for Incurables.

Philip Crampton Smyly, M.D. University of Dublin, F.R.C.S.I., L.K.Q.C.P.I.; Rawdon Macnamara.

R. Perse White, F.R.C.S.I., L.K.Q.C.P.I., late Surgeon to Jervis street Hospital.

Robert St. John Mayne, L.R.C.S.I., L.K.Q.C.P.I., Lecturer on Anatomy at the Carmichael School of Medicine.

The Ensuing WINTER SESSION will commence on 1st of OCTOBER, and the COURSE of CLINICAL LECTURES on the First MONDAY in NOVEMBER.

Clinical Lectures, of which four will be delivered weekly, and instructions in Medicine and Surgery, will be given on alternate days.

The Physicians and Surgeons will visit the Hospital at Nine o'clock, a.m., so as to allow the Members of the class to be in attendance at their respective Schools of Medicine at Eleven o'clock a.m.

The Hospital, which contains 120 beds, for the reception of Medical and Surgical cases, and to which an extensive Dispensary (open daily) and Lending Library are attached, is within a few minutes' walk of the University, the College of Surgeons and the Ledwich Schools of Medicine.

An additional Ward has been recently erected for the reception of Children, in which the Pupils will have an opportunity of studying that highly important subject—Infantile Disease.

Certificates of attendance at this Hospital are recognised by all the Universities, Colleges, and Licensing Bodies in the United Kingdom.

Prizes will be given at the termination of the Winter Course to the best answerers in their respective Classes.

The office of Resident Pupil is open to Pupils as well as Apprentices. In addition to the above, Doctor HUDSON has presented a Prize of Ten Pounds, to be competed for on conditions to be determined by the Physicians.

Further information may be obtained by application to

ROBERT ST. JOHN MAYNE, Esq., Hon. Sec.

8 Rutland square East, or at the Hospital.

Dublin, September, 1871.

**HOUSE - SURGEON WANTED,** at the GREAT NORTHERN HOSPITAL, Caledonian road, N. Candidates (M.R.C.S.) are invited to send their application and copies of testimonials to the Secretary, 46 Great Coram street, W.C., on or before 30th October.

By order,

GEORGE REID, Secretary.

# The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 25, 1871.

## Original Communications.

### NOTES ON THE ORIGIN OF SYPHILIS.

BY DR. CHARLES R. DRYSDALE,

Physician to the Metropolitan Free Hospital, &c., London.

THE writer of these few lines has recently been reading over many of the works which treat of the origin of syphilis; and, commencing as he did with an opposite opinion, has become gradually convinced that the epoch of the origin of the disease was that of the landing of the crews of the ships of Columbus in 1493, in Lisbon, Seville, and other parts of Spain. In a visit to Paris this summer (1871), he found that Dr. Alfred Fournier, also, had become quite a partizan of this side of the question; whilst the excellent work of Mr. Gaskoin, "On the Life and Writings of Dr. Lobos di Villalobos," has made the English medical public familiar with the idea of the disease being imported from America. The following notes, made from a most excellent paper on this subject, in *Lo Sperimentale*, Oct., 1871, are, the writer believes, most conclusive; written as they are by Dr. Ferrari, the well-known surgeon of Pisa. As the essay is in Italian, it is possible that it may not be so widely read as it ought to be, unless rendered into English. Such authors (says Dr. F.) as believe in the ancient existence of syphilis affirm that, not only Job, and King David, but, also, that the Emperor Augustus suffered from this disease, and also Tiberius Cæsar, and Galerius Maximus. They also quote Hippocrates who, in one phrase, in his treatise *De morbis*, speaks of "pustulas magnas, et pustulas corpori universo erumpentes ulcera fœdissima circa pubem." Dr. Verneuil, of Paris, has recently published some documents (*Arch. gen.*, Paris, 1863), which seem to show that the Chinese, long before the Christian Era, besides knowing very well the venereal diseases, had known too about mercury as a most efficacious remedy against syphilis. This, perhaps of all documents, the one which, if genuine, would prove the antiquity of syphilis, is due to Captain Dabry, French Consul at Hang-

Kean, in China. This gentleman asserts that the document in question had been extracted from the treatise Nuei-King, written in the reign of Hoang-ti, or 2,637 years before Jesus Christ. (*La Méd. Chez les Chinois*, Paris, 1863.) But we easily begin to doubt of the authenticity of this work, when we notice the great precision of the descriptions of syphilis made there, in comparison to the times in which they were written. Indeed, there is in this treatise a most exact description of gonorrhœa, of indurated ulcers, phagedænic, and serpiginous sores, or intra-urethral sores, of buboes and warts, and likewise of the secondary symptoms occurring after syphilis. And, then, most notable of all, mercury is described as a quite specific remedy, even in these days. And another argument against our belief in this document is, that there is no mention made of hereditary syphilis in it. Although M. Robert, of Paris, thinks that Job in the Bible was afflicted with syphilis, it seems much more reasonable to suppose that his disease was leprosy; and as to the pains in the bones spoken of by King David, there is not the slightest proof of their having been of a syphilitic nature. As to the expression above quoted from Hippocrates, there seems no reason to say that the ulcers mentioned were syphilitic; they may just as well have been scrofulous ulcerations. Littré, the French medical writer on philosophy, says: "No trace of syphilitic affection is seen in antiquity; but a crowd of affections of the genital organs are noticed there, which do not refer to any syphilitic speciality."

Whence, then, did the disease come to us? Although the Americans accuse the Europeans of having carried this disease to them, nevertheless, according to the opinion most universally adopted by the learned men in the congress of Nantes, in 1835, it would seem that it is a disease of very ancient origin in America, and that, according to Bechi and Sanchez, it came to Europe only at the end of the 15th century, brought by the companions of Columbus. And there is, indeed, a most powerful argument to prove this in Columbus himself, who asserts that, when he returned the second time to the New World, he found among the Spaniards who had been left there, to study the manners of the savages, a monk, who, having learnt their language, was able to tell him what he had

observed, and particularly the fact that, among the Indians, there existed very commonly a disease which they called *caracacacol*, and which showed itself as a scab over the body. This, too, is just the time, when we see arise throughout Europe, for the first time, syphilis among the nations. Antonio Benivieni, a most distinguished physician of that time, writes: "Novum morbi genus anno salutis nonagesimo sexto supra mille quadringentos a christiana salute non solum Italiam sed fere totam Europam irrepit. Hoc ab Hispania incipiens per Italiam ipsam primum tum Galliam Ceteresque Europæ provincias late diffusum mortale quamplurimas occupavit." And in the same strain wrote Alessandro Benedetti (1496); Corradino Gilino (1497); Gaspare Torella (1497); and Bartholomeo Montagnana (1498); and a little later, G de Vigo (1514); G. Fracastor (1546); Antonio Brassavola (1553); and Gabriel Fallopius (1566). And if we desire yet ocular testimony, we may cite the physician Diaz di Isla, and the historian Oviedo, who both had numerous opportunities of speaking with Genovese, in Barcelona. Besides these, Guicciardini and Bembo, speak of it as quite a new disease.

The 4th March, 1493, was the miserable day, in which syphilis appeared in Europe—Lisbon, Seville, Barcelona, and Gallizia, and, where the ships of Columbus landed, these were the first spots rudely infected. In Barcelona, as Diaz di Isla narrates, the venereal disease was shortly so spread, that public prayers and fastings were offered up to God, in order that they might be delivered from it. When in the month of August, 1494, Charles VIII went with a large army to Naples to conquer that kingdom, from thence gradually also in Italy did the terrible disease manifest itself, so that the French called it *mal de Naples*, and the Italians called it *mal francese*. Lastly, the return of these soldiers to their native land, diffused syphilis in Switzerland, France, and in every other part of Europe abundantly, and by commerce it thence passed on to the coasts of Africa, among the Turks, Persians, Chinese, and people of Japan. In those days, too, syphilis showed itself with much greater gravity than at present; both primary and secondary symptoms also came on more rapidly. Christoforo Girtanner says: (*Trattato s. la mal. Ven.*, Venice, 1801), that a few hours after impure congress, there showed itself in the prepuce or gland a rather itching vesicle, which quickly opened and became a chancre. In a few days universal lues followed. Over the whole body and face there appeared pustules the size of a pea, or sometimes a little nut, sometimes a little larger. These appeared red and inflamed, and were accompanied by great pain, but did not pass into suppuration. To this were associated most cruel pains in the bones by night, and exostoses of all kinds, which became inflamed, and sometimes degenerated into caries. Cataneus describes it as: "Monstruosus morbus nullis ante sæculis visus totoque in orbe terrarum incognitus, fœditate magna, innumeris pustulis ulceribusque per totam faciem universumque corpus mulieres virosque deturpans." And that the disease declared itself in a most terribly frightful manner, is proved again, in that the poor patients were, from the first, abandoned by everyone, and even by the physicians, who, however, becoming so ashamed that the sentiment of charity was extinguished in them, along with the love of science, commenced soon to think seriously of how to succour them. Also the Parliament of Paris in its decree of March 6th, 1497, expels from Paris all who were suffering from the *grosse verole*; also adding that the poor were to be transported to Saint Germain des Prez., where they were abundantly provided with necessaries. A similar law was passed in the same year, by the King of Scotland.

Twenty-five years after this, syphilis began to become more mild, and its contagion more restricted, its symptoms less intense, and death less speedy, and especially much rarer; but what is singular is that, just as the disease diminished and became less malignant, its manifestations increased in number. From this circumstance, the physicians who studied this disease discovered many new facts regarding it. In fact, G. Torella, among the first, and

then Sebastian Aquilanus, Cataneus, Benedetti, Massa, Fallopius, Botallus, and many others noticed that syphilis was able, also, to be transmitted by nursing. Paracelsus says that: "Le mal français nait non seulement de Venus, il se transmet par l'hérédité." Vigo, in 1514, speaks of the exostoses, and distinguishes syphilis into confirmed and non-confirmed; and further on Massa says that, syphilitic dyscrasia only follows after non-suppurating buboes. Fracastor, Monti, Benedetti, Lenocenus, and Cumanus, and Torella, exclude suppurating buboes from among the symptoms of syphilis; and Torella, Pario, Francanziano, and Botallus, remarked that the ulcer of syphilis is hard and indolent. Gaspare Torella (1498), remarked that dry eruptions are generally seen in syphilis, and Benivieni (1502) says that large pustules which become ulcerated, were the rarest forms of syphilitic affections. Torella, the most celebrated writer on syphilis of his times, divided syphilitic skin diseases into dry and moist. Benivieni described five species of syphilitic pustules; and Fallopius distinguished them into *pustulæ sine cortice*, and *pustulæ cum cortice*.

### ON COUP-DE-SOLEIL IN INDIA.

BY JAMES C. DICKINSON,

Surgeon to the St. Marylebone General Dispensary, and late of H. M. Bengal Army.

WHAT treatment are we to adopt in cases of sun-stroke? This is a question frequently put by medical officers to one another on arriving in the tropics, but seldom if ever is a satisfactory reply obtained. Information on the subject is to be gleaned neither from the works of Martin or Morehead, while the few papers that have been written on the subject are to be found with difficulty. Any clinical observations illustrative of the symptoms and treatment of this somewhat obscure disease, cannot but prove interesting, and with this hope it is that I submit this paper on a disease which appeared in almost every European regiment during the Indian mutiny, whether in quarters as in H.M. 19th Regt. in Fort William, on active service in the field as in H.M. 6th at Sasseram, or living in tents during the hot and rainy seasons as in H.M. 13th Light Infantry at Gorrickpore.

Again, when is it borne in mind that we are sending annually large bodies of European troops to India, I consider it the duty of all military surgeons to report every case of sun-stroke that comes under their notice together with the treatment adopted. By such means we may hope ultimately to ascertain what the essence of the disease is and consequently lessen the mortality.

The men who came under my notice were living in tents during the months of May and June, the thermometer was standing at 98° to 100°. The cases generally occurred about 4 p.m. which may be considered the hottest part of the day. On arrival at hospital, the men who were seized all more or less presented the following symptoms which I term the *first stage*:—Face much flushed; eye restless and brilliant; conjunctivæ congested; an anxious expression of countenance; tongue thickly coated with a white fur; pulse quick; questions correctly answered, although there is a disinclination to do so, but no incoherence. On enquiry the previous history will generally be found to be somewhat as follows:—the appetite for some days past had fallen off, and the bowels had been costive. Just prior to being brought to hospital, the men had complained of faintness and giddiness, and a sensation as if they had been struck on the back of the head, and becoming alarmed, had requested their comrades to take them to the doctor. Almost immediately after their arrival, I noticed a new train of symptoms setting in, constituting what I term the *second stage*. Here we find the skin of the whole body intensely hot and red which is very marked on the head and chest, the intensity of the heat is most singular, it exceeds in degree everything I have ever seen, and once noticed can never be mistaken. There

is violent palpitation of the heart, the pulsations of which are observable at the scrobiculus cordis. The throbbing of the carotids is so violent, as to be remarked by the bystanders; the patient throws himself violently about; his speech becomes thick, inarticulate and ultimately ceases. The teeth become firmly set; there is great rigidity of the masseter muscles; the patient steadily refuses to swallow anything, and any attempt to enforce liquid is almost if not quite impossible, and the attempt to do so is apparently attended with great pain; there is more or less tonic spasm of the muscles of voluntary motion. The symptoms in this stage are such as to render it difficult to divest one's self of the idea that you are not witnessing a case of acute trismus. In the *third or last stage* the patient either gradually sinks from exhaustion or sensibility returns *pari passu* with the lessened force of the circulation, the patient being left in a debilitated and low condition.

In the treatment two things are necessary: first from the tendency to death by exhaustion we must be careful to support the powers of life, and secondly on account of the general excitement that prevails, we must be careful to employ such remedies as will allay it as speedily as possible without exhausting the patient. Immediately a patient is brought into hospital supposing the second stage not to have supervened, I administer a purgative draught composed of rhubarb, senna and salts, followed by an enema of castor oil and turpentine. These medicines I give almost simultaneously, because if the purgative should be rejected (which often happens), then no time has been lost to ensure a speedy action of the enema. It should be recollected, that the success of your treatment depends on the rapidity with which your remedies are administered. Again if the purgative is not rejected so much the better, for as I have already noticed, there is evidence of a foul state of stomach. There is obstinate costiveness to be overcome, and there is the heightened circulation to be reduced; the former has been met with its appropriate measures, to the latter symptom now it is that we must address ourselves.

This the reduction of temperature and force of the circulation, is effected by means of a stream of cold water poured from a height over the whole body, particularly the head, spine, and chest. In employing this remedy there must be neither fear nor hesitation exhibited. The patient should be stripped, placed in the verandah, and supported in the sitting posture. Two Bheestees (water-carriers) should be placed either on a table or some other high place, and be told to direct the streams of water from their mussucks (a pig skin which contains the water), one over the head, the other over the cardiac region. These first two mussucks generally produce a decided although not a permanent effect on the pulse, and assist in diminishing the fulness of the cerebral vessels. Then I keep one mussuck at work, gradually reducing the force of the stream of water as the force of the circulation diminishes. The time occupied in the administration of the cold water varies from an hour to an hour and a half. The rule to be guided by in the employment of the cold stream—our sheet anchor—is to continue pouring on the water *till the very slightest tendency to re-action shows itself*, then and not till then leave it off. When this is accomplished, the patient should be dried and put to bed. He then generally falls into a sound sleep for a few hours and awake perfectly conscious, the skin will be found moist and cool and the pulse soft and regular. The after treatment is very simple. Quinine in small doses two or three times a day with a light nourishing diet, attention paid to the bowels, and a cold douche every morning is all the after treatment necessary. Bleeding formerly had its advocates, and although for some years it fell, most properly I think into desuetude, it has again been revived.

The following case shows in my opinion the extreme danger and inutility of bleeding.

A serjeant of the regiment, tall, and powerfully built, plethoric in appearances, but of steady habits, was one of

the first cases I met with of sun-stroke. At the suggestion of a brother medical officer, we bled him to  $\zeta$ xx., the sedative effect was but momentary, and the re-action set up was of a very alarming character, it was then a question what treatment to pursue. Should the bleeding be repeated? give chloroform, or opium, or try the cold douche? I determined upon the latter, because I knew the real value of the remedy, whereas if I gave opium I might not allay the re-action soon enough. Chloroform I considered contra-indicated, inasmuch as the regiment had lately arrived from the Cape, where disease of the heart is so commonly engendered, and also because from the excited state of the circulation it was difficult to recognise the actual condition of the heart, so that had the patient at the time of the administration of the remedy died, it would have been problematical to have said whether death was the result of the disease or the remedy. It may also be worth while to remember, that chloroform has its enemies in India as well as in England, and should therefore be given with caution. Having myself given chloroform with much success in that active form of mania attended by sudden outbursts of emotional feeling as well as in delirium-tremens, it is possible in some exceptional cases of sun-stroke it might prove useful.

The pathology of *coup-de-soleil* we know very little of, and in order to ascertain what constitutes the essence of the disease, would require the collated evidence resulting from the examination of all fatal cases, and even then I fancy, judging from my own observations, we shall find little more than congestion of the vessels of the brain with occasionally fluid in the ventricles, together with a more or less congested condition of the lungs.

Dr. Norman Chevers, whose observations and opinions are entitled to the highest respect, is of opinion that the immediate cause of dissolution is a deficient supply of arterialised blood to the brain, and adds that this malady is usually followed by a large crop of boils. Some writers again are disposed to look upon the disease as being what Mattatenci termed a polar state of the nervous system, while others again believe it to be principally due to hyper-irritation of the spinal cord.

The number of cases treated by me were fourteen, they were admitted to hospital in the months of May and June, and all were discharged well with the exception of the man who was bled, he died from exhaustion. All the cases treated by me occurred shortly after active operations in the field had ceased, clearly showing that the constitution is able to resist the vertical sun so long as it is aided by what Julius Jeffreys calls the "elating excitement."

*Prophylactic measures.*—The men of every regiment should have explained to them on their first arrival in India, the danger of unnecessarily exposing themselves, and of the importance of never going out in the sun without their hats. Over-indulgence in food equally with excess in drinking should be strictly enjoined, as the history of more than one case proves to such excesses are predisposing causes. If campaigns or marches must be made in the hot season, I would suggest that soldiers should wear flannel coats. The natives who suffer from sun-stroke when out walking in the hot season, cover their heads and bodies with a blanket. The helmet should always be lined inside with flannel, this was suggested to me by one of the greatest sportsmen in India, who in the hottest weather has been out all day tiger shooting, and never since adopting this plan suffered any inconvenience. The ordinary cane helmet having a quilted cotton cover and lined inside with flannel, will be found the best and cheapest head-dress.

When a patient recovers from sun-stroke, the military surgeon has to consider what symptoms are likely to follow and whether he is justified in bringing the case before the Medical Board with a view to sending him to England. No surgeon of any experience would even hesitate, at once granting a certificate, and my advice to young surgeons is to do the same.

The results of sun-stroke may be briefly summed up as follows:—complete recovery, twenty per cent.; followed

by temporary loss of memory, twenty per cent.; liability to headache for some years afterwards, thirty per cent.; madness about five per cent.; deaths twenty-five per cent.

Patients on arrival in England, should visit healthy bracing climates. In Wales and Scotland, but especially Laurence-on-the-Sea. Those to whom time and money are of no object, I recommend spending a season at Gastein in Austria, the mean summer temperature of which is only 59° F. This climate, together with a course of bathing, has much benefited those who have had sun-stroke, as well as those old Indians who suffer from nervous exhaustion, brought on by excessive mental labour, or the result of cachexia loci.

### ON MENINGITIS AS A CAUSE OF DEATH IN INFANTILE CHOLERAIC DIARRHŒA AND CHOLERA.

By WILLIAM CURRAN, L.R.C.P. Ed., M.R.C.S., Lond., &c.,  
Army Medical Staff.

(Continued from Page 336.)

Copland ascribes the following symptoms to an attack of acute meningitis:—"Acute pain in the head, with intolerance of light and sound, watchfulness, delirium, flushed countenance, and redness of the conjunctiva, or a heavy suffused state of the eyes, quick pulse, frequently spasmodic twitchings or convulsions passing into somnolency, coma, and complete relaxation of the limbs," and though some of these were conspicuous by their absence in one or another of the cases that came under my notice, and though others are not always easily recognised in very young children, still the general effect is substantially the same in all, and I trust it will be allowed, that the experience I have had in the matter will justify me in assuming that no grave diagnostic error was made in either of the instances under review.

CASE I.—Mervin Mooney, æt. thirteen months, a weakly, scrofulous-looking child, that has not yet been weaned, was admitted late in July with symptoms of cerebral irritation, probably induced by recent exposure and certainly aggravated by the presence of an exhausting quasi choleraic diarrhœa. Has been under treatment at head-quarters, and the mother says that it has been troubled after being previously confined, with looseness for several days back, and that for the last five at least it has been losing strength, gnashing its teeth, and at times wailing plaintively. When seen by me the child was very restless and irritable, the pupils were contracted and very sensitive to a sudden access of light, and he endeavoured to shade his eyes or bury them in the bed, whenever the purdah—screen—was withdrawn, or there was any other unusual movement in the tent. The face was pale but somewhat pinched, and expressive of suffering, he moaned feebly from time to time and now and then shrieked out loudly, and he preferred lying with his head thrown back on the mother's arm. He either struggled convulsively against his food and physic, or took both without making any resistance, and as if mechanically, the least disturbance called forth a shrill querulous cry, and the fingers wandered occasionally over the head as if in quest of something near the forehead and temples. The temperature though much increased was not excessive, but he could bear no pressure over the cranium, and his peevishness and irritability increased apace, some puffy discolouration and ecchymosis of the conjunctiva set in, the urine scanty from the beginning, became almost suppressed or dribbled unconsciously from the bladder towards the end of his struggle, and the discharges from the bowels were throughout watery, offensive, and at times passed involuntarily. These general symptoms increased in severity soon after admission, food did not appear to nourish the body, or physic to control the pro-

gress of the disease, the thumbs were all along firmly flexed against the palms, and spasmodic twitchings having appeared in the legs and fingers, the child died convulsed, a few days after arrival in camp.

CASE II.—Margaret Henry, æt. one year and eight months, a strong, healthy child that does not appear to have suffered much from the irritation of teething, was found, on admission to hospital, on the morning of the 3rd of August, to be suffering from cramps and diarrhœa. The surface was cold and covered with the remains of clammy perspiration, and the face was livid and depressed. Chlorodyne and champagne afforded temporary relief, a warm bath somewhat restored the suspended action of the skin, and aromatic confection, tincture of cinnamon and chalk mixture, mitigated the severity without materially diminishing the frequency of her discharges. These had now become watery and choleraic, nevertheless her expression was not much altered for the worse, and the purging did not appear to reduce her strength, or precipitate unduly the result that followed. There could, however, be no longer any doubt as to the dangerous character of her complaint, and she remained about this time, for upwards of two days, in a state that fluctuated between fear and hope, and which augured unfavourably of her ultimate recovery. Thanks, however, to her own good constitution, and to the affectionate nursing and the unflagging devotion of her mother, she rallied for a time, and I had even some hopes of seeing her restored ere long to her family. But this was not to be, and I soon afterwards recognised with sorrow, in her flushed face, pinky suffused conjunctivæ, and plaintive querulous manner, the influence of a complication that would, I anticipated, baffle all my efforts, and finally destroy life. A blister was placed on the nucha, mercurial inunction was practised to inner aspect of thighs and under arm-pits, and calomel in small doses was given by the mouth. She was so drowsy and somnolent as to look like a person who had taken too much opium, but the pupils, though dilated, were brilliant and glistening, there was frequent knitting of the brows, and she could never quite succeed in closing the eyelids. All her senses, in fact, became morbidly active, she appeared to listen for sounds that no one else heard, and to see, nay, even shrink from objects that were quite invisible to others; the fingers were firmly clenched, and there were now and then some suspicious twitchings about the mouth and nostrils. I fancied I discovered a trace of sugar in the urine about this time, but the supply was so scanty, and the appliances at my command for purposes of examination were so imperfect, that I could not quite satisfy myself on this head; it had, however, a saccharine odour, and the surface-scum contained a product which I could only compare at the time, and with such a glass as I possessed, to the fungus of the torula cerevisiæ. As it was now clearly necessary to obviate the tendency to death, æther in ten minim doses was allowed every hour, and the champagne and suppositories were continued. These, however, exercised no material check upon the intra-cranial effusion, and profound coma, with relaxation of the sphincters soon set in. The breathing, which was always noisy, and sometimes whiffling, now became stertorous, and she puffed at intervals from left corner of mouth, the pupils lost all sensibility, the conjunctivæ became bloodshot and congested, and, retaining her florid look to the last, she passed away unconsciously ten days after admission.

CASE III.—That of Stephen Waishe, æt. one year and eight months, need not detain us long, for the result was the same, and the symptoms preceding it were substantially identical with those already recorded. They were, however, more rapid as regards their onset, than in either of the former instances, and as will be seen from the sequel, they terminated more speedily in death than was the case in the two former. Admitted to hospital with a choleraic seizure of average severity; he was described the day following as having spent a very restless night, starting up at intervals to stare vacantly about, or flinch,

with a look of alarm at some imaginary object, and then suddenly throwing his head backwards to gasp and struggle as if in convulsions. The temperature of the scalp and forehead became subsequently much increased, the pulse, at times, almost exceeded counting, there was frequent knitting of the brows, and the left eye was affected with convergent strabismus. The mother was more than once alarmed at the strange sardonic expression of his face, and the twitchings that took place near the angles of his mouth, and she adds that he frequently trembles all over, as if under the influence of aguish disorder or fear. He rejected impatiently the attentions she lavished on him; cried without cause in a peculiarly harsh and abrupt manner, and then, relapsing into a condition that bordered on stupor, sighed faintly or scratched feebly at the forehead. The pupils, at first contracted and ferrily became, as the disease progressed, dilated and insensible, the expression was always indicative of irritation or pain, and whenever the act of vomiting caused him to unclothe his eyes, he shrank back with an angry whine and covered his face against the light. The treatment enforced resembled that already described in connection with the last case, and we took frequent advantage of his almost insatiable thirst to supply nourishment to the system. But all our efforts were fruitless, for he pined away apace, the sphincters lost their contractility, and puffing abdominal breathing having superseded the more natural pulmonary process, he died quietly six days after admission.

I must here take the liberty of cautioning the Society against the impression which a perusal of the above is calculated to foster, that all cases in which similar symptoms are well developed, almost necessarily prove fatal. This result does not, according to my experience, always follow, and I was particularly pleased to find that a sturdy little fellow who came under my notice sometime later, and almost simultaneously with the cessation of the epidemic influence above referred to, and in whose case there was "that sudden and long-continued paroxysm of *general convulsions* which," Sir Thos. Watson regards "as the most common and striking phenomenon of the disease," recovered well and is now quite free from all trace of his dangerous attack. I will only add that I had no opportunity of verifying after death the conclusions I arrived at during life. My countrywomen are notoriously opposed to investigations of this kind, and it is a rule of the department that no examination shall take place against the wishes of a surviving friend or relative. In justice to myself, however, rather than out of any distrust of your courtesy, I will merely observe that the first case recorded here was previously under the care of my senior colleague, and that "on returning" it under the head of meningitis, and saying that I knew of no other condition to which it could be ascribed, he freely endorsed my view, and said that such was from the beginning his own belief.

With regard to the causation and pathology\* of this grave complication, not much, I think has been satisfactorily ascertained and little accordingly need be said here. Cerebral pathology is still, to some extent, a sealed book, and the contradictory opinions given by experts in courts of law, and the different interpretation put by alienists and others, on the same symptoms under precisely similar conditions of time, place, and constitution, afford a striking proof of this. So exquisitely sensitive is the brain in early life, so liable is it to sympathise with morbid alterations of structure or diseased conditions elsewhere, and withal so uncertain, and ill-defined is the connection between the results of dissection and the phenomena of disease, that fancy has free scope to roam as it list, and derive such aid from hypothesis and conjecture as it may not command at the hands of actual examination or clinical research. Sir

\* See further the article "Simple Meningitis," by J. Spence Ramskill, M.D., in Reynolds's "System of Medicine," vol. ii., pp. 354-361, &c., which is about the best on the subject that I am acquainted with. West appears to me to confound or identify the disease with acute hydrocephalus, and I have just now no other authorities by me on the subject.

Thomas Watson, after quoting a case in which vomiting and convulsive movements of the face and arms were the only prominent features observed during life, says, "We learn from this case that general and severe inflammation of the innermost membrane may exist and prove fatal, without giving rise to any violent symptoms at all." He elsewhere adds that, "Inflammation of the meninges often commences and declares itself by no fixed or uniform symptoms;" and the following words of Copland must command an approving response, from all who have had much to do with the treatment of brain disorder. "The most violent symptoms referable to this organ, the brain, often exist during life, and yet, on the most careful examination, after death, either no appreciable lesion, or none sufficient, to account for the phenomena can be detected; whilst, on the other hand, many and most important changes are frequently discovered in both the brain and its membranes in cases which betrayed either no cerebral disorder, or none calculated to excite suspicion during life of any organic change." Keeping these pregnant considerations and well-authenticated facts in view, and coupling them with the equally well-ascertained physiological relations of the cerebral substance itself, that it is enclosed in an unyielding bony case, which admits of no material increase or diminution of its normal contents, that it is (in infancy at least), unusually sensitive of impressions from without, and of a form and consistence that readily betray the presence of a foreign element, without, at the same time, supplying any very reliable explanation of its nature or locality, we will easily recognise its great liability to functional disturbance, and see how soon it can be stimulated into disease by an excess or stoppage of its supplies. Distal irritation of the sympathetic, by paralysing or unduly exciting the fine ganglionic filaments of the cerebrum, can produce hyperemia, partial remora, or entire stagnation, and lead to either capillary congestion, the formation of false membrane, or effusion into the ventricles. The result would be pretty much the same in either case, the symptoms would not be far different, and though, as stated before, I had no opportunity of verifying my suspicions by actual inspection, I fully believe that effusion was the predominant feature throughout.

Thus far, have I ventured to trespass on your time in the discussion of a subject which can boast, at least, of very little novelty and almost no interest. I have, as I said above, selected it out of regard for the convenience of the meeting, and because I could find nothing else connected with the malady with which we are all unhappily but too familiar out here, which has not been better handled elsewhere. The statement has occupied more space and assumed greater dimensions than I at first contemplated, or can now control, but if it has shown, as I venture to think it has, that meningitis is a more frequent cause of death—during epidemic seasons—in infantile diarrhoea and cholera than is generally supposed, I have fulfilled the object I had in view in drawing it up, and I have purposely abstained from going into those collateral considerations of prevention, treatment, comparative diagnosis, &c., &c., which, however relevant to the general issue, would be out of place on an occasion like the present, and which will, in any case, easily suggest themselves to every observant and educated mind.

#### HOSPITAL TEMPERATURE.

By FRANCIS R. HOGG, M.D.,  
Royal Horse Artillery.

AT the Garrison Female Hospital, Woolwich, from June, 1862, to October, 1871, the number of parturition cases amounted to 1,050; also in round numbers 570 sick women and nearly 300 children suffering from diseases—not of infectious or contagious character were treated.

Patients came in who had been doubled up four families together in a barrack room—from cottages where in a single apartment a man, wife, and five children had

been located—from damp huts—from dirty, ill-drained lodgings, badly supplied with water. Also from camps, marches, and long sea voyages, where personal cleanliness was impossible.

Friends also recovering from fever, or having children down with scarlatina, will, in culpable ignorance, or reckless indifference, visit patients. In December, 1866, a miserable child suffering from *tabes mesenterica* developed and communicated scarlatina to a leg fractured woman; both cases removed recovered.

With these exceptions no case of scarlet fever has occurred for more than nine years.

The clothes of patients are kept in a store adjoining the wards.

Now, the temperature of these two wards during the month of December, 1870, ranged from 36 deg. Fahr. to 57 deg., the average being 45 deg.

For instance, Christmas Day 38 deg. in the morning 39 deg. at night, in a ward containing eight recently confined women. In the middle of the night, December 27th, the water-pipes bursting through hard frost, this parturition ward was flooded, and nine patients with their young infants were removed into the general ward without sustaining the slightest injury.

Whenever European women and East Indians are in the same room, fever lurks about—to the best of my belief two deaths thus originated.

The influence of panic must not be overlooked—a woman dies suddenly or after confinement; immediately all the others of nervous temperaments become feverish, or their suckling infants develop convulsions. Returning to immediate subject, although such diseases as bronchitis, pneumonia, peritonitis, and rheumatism require warmth, a low temperature is absolutely necessary for parturition, and this same low temperature will retard the blaze of scarlet fever. In the language of Trousseau “As the seeds found in the tombs of the Pharaohs germinated and fructified after a lapse of more than three thousand years, just as if they had been gathered on the previous days from the parent plants,” so do the morbid germs of certain diseases, remaining latent to an indefinite period, under certain circumstances, burst out with malignant fury when warmed in congenial soil.

## TREATMENT OF SUPERFICIAL ABSCESS IN THE NECK.

By RICHARD CREAN, L.K.Q.C.P.I.,

House-Surgeon to the Clinical Hospital for Sick Children, Manchester.

THIS is a subject that has long engaged the attention of practical surgeons from the deformities consequent on their healing. They are of frequent occurrence in strumous and debilitated children, and are a common sequelæ to infantile fevers. Comparatively rare in the country, all the causes of debility, such as improper food, impure air, neglect of cleanliness, &c., combine to render them the pests of our large towns. Being generally painless in their progress, the mother dreads not so much present suffering as the future unsightly scar which popularly marks its victim as suffering from “the evil.” Epidemics of measles, scarlatina, and small-pox, entailing the usual legacies, have afforded me during some months past an extensive opportunity of comparing the different methods of treatment. The ugly and puckered cicatrix which in many cases followed the routine plan of treatment by cod-oil, poultices, and incisions, rendered it doubtful whether Nature alone might not have been more successful in her efforts. The inutility of the present methods of treatment is pointed out in Holmes’ “Surgery,” where the able writer of the article on abscesses, in referring to this particular class, says, “that as a rule, no good ensues from opening these abscesses. The surgeon had better rely on general measures.” It was with pleasure, therefore, that I hailed Mr. Lawson Tait’s remarks on the successful tapping of these collections, a success

which I had an opportunity of personally verifying in one instance.

Further experience, however, convinces me that, although successful in some, it is unsuitable to many cases.

Two classes of cervical abscess are met with in children. In one suppuration occurs in the tissues around the lymphatic glands, and its progress, though not rapid, is marked by an activity and vigour not characteristic of the other. In the second form tubercle is usually deposited in the substance of the gland, and a slow and painless enlargement follows. Sooner or later, in general, softening succeeds, and with tortoise-like pace the abscess advances to the surface. The inflammatory symptoms are less intense. Pointing takes place, and instead of the homogeneous liquid usually found in the first variety, the discharged matter consists of cheesy flakes in a thin, turbid, and yellowish serum. Independently of the trouble, pain, and tediousness of the process, the physical difference in the contents of the abscesses would of necessity preclude the universal employment of tapping in these cases. Two cases lately under my care offer a marked illustration of this. In the first, tapping had the happiest effects; in the second, despite repeated and carefully made punctures with Wood’s syringe, a solid, though small swelling remained after the evacuation of the fluid contents. A fortnight afterwards inflammation of the gland recurred. It burst, and left a puckered scar. Short notes of a case published by Dr. Murray, of the Middlesex Hospital, in the *British Medical Journal* last February, when he used a silk thread, and afterwards a piece of fine cat gut steeped in carbolic acid induced me to try a similar plan. In my first case I used silk, but found this acted as an irritant, extending the inflammatory process beyond its former limits. Next time I substituted silver wire, and I found this answer its purpose so well that I have not cared about exchanging it for catgut. I have now used it in twenty-eight cases, and in all it has afforded me great satisfaction. In a few weeks—sometimes in a few days—after the introduction of the wire, nothing remains to mark the site of the abscess except perhaps some induration or slight lividity of the skin, which in turn disappears.

Short notes of the two following cases will serve as an illustration of its advantages:—

CASE I.—J. S., æt. nine years, of marked strumous appearance, and suffering from chronic affections of the scalp and conjunctiva, was brought to the Dispensary on the 2nd of April. An indurated gland situated beneath the angle of right jaw, after remaining quiescent for five months, had taken on suppurative action, and now formed an indolent abscess of fair size. A piece of fine silver wire was introduced, formed into a loop, and secured in position by means of a strip of adhesive plaster. In forty-eight hours the sac was completely emptied, and in a week all trace of it had disappeared.

CASE II.—A. M., æt. three-and-a-half years, convalescing from measles, is suffering from a painful induration in right submaxillary space. Quinine and poultices of fresh hemlock leaves were ordered, the latter of which I have found a very efficient agent in dissipating painful glandular enlargements. In a week the centre of the tumour had softened, and was threatening to burst, while the circumference preserved a firm consistence. A wire was passed through the base of the abscess, and was left there for a week. On removal a little thickening and hardness were still perceptible to the touch; but gentle friction for a short time with camphorated oil dissipated this.

I trust these few remarks will induce my professional brethren to give a fair trial to a painless, unirritating, and in my practice, very efficacious mode of treatment.

It is reported that an epidemic of small-pox has broken out in Wolverhampton, and that between two and three hundred cases are under treatment.

## Foreign Medical Literature.

### NEW AND VARIOUS APPLICATIONS OF GUERIN'S WADDING-DRESSING.—PRECAUTIONS TO BE TAKEN.

Translated by FRANCIS M. LUTHER, M.D.

(From the *Journal de Médecine et Chirurgie Pratiques*, for October, 1871.)

WADDING-DRESSING so happily modifies the sequelæ of capital operations, that one's attention being caught by this result, may be turned aside from conservative surgery. However, it must be allowed that the wadding has done wonders in fulfilling the indications of this department of surgery, as well as in amputations. The first and the most remarkable case at Hôpital St. Louis, was that of a child nine years old, a great portion of whose hip and abdominal parietes had been torn by a splinter of a shell. The soft parts of the abdominal walls were destroyed to that degree, that one could distinguish the outline of the coils of intestine delineated underneath. However, the next day the patient felt well; calomel was given to it in minimum doses. Then it remained for twenty days without being dressed. At the end of that time, a granulating wound was revealed; in the dressing was the detached iliac crest. Gradually the wound contracted, then as the child was scrofulous, a good deal of cod-liver oil was given to it, and it was sent home to complete its cure.

From this date, the employment of wadding for all sorts of cases, became habitual in the practice of M. Guérin. Among the most remarkable results, let us particularise three wounds of the ankle-joint. We saw the dressing removed on the thirtieth day from one of those patients who had first been treated by cold applications, which by no means agreed with him. It was a large wound with fracture of the bones. At the first re-dressing of the wound, although the pus was abundant it was superb, and his health kept up very well.

Some other cases are interesting to pass in review. A man wounded in a saw-mill, had the first metacarpal bone gouged off. The pain was so acute that it was very difficult to dress it. In the evening he felt so well that he demanded his discharge; though in the morning he had been most anxious to obtain a bed. Next day having workmen to overlook, he passed the day in the workshop with his hand in a sling; thenceforward he continued without losing a day's work. He returns periodically to St. Louis, and we saw his hand nearly cured.

Another extern patient had two metacarpal bones broken by a gun-shot discharge. We saw his wound opened and dressed upon the twenty-third day. It would have been easy to delay this dressing for several days, the result was excellent.

A man, æt. sixty-three, had the right upper extremity crushed between a wall and a scavenger's cart. The hand appeared pounded into jelly, it would have to be a case of amputation, singularly complicated by the fact of a fracture of the upper extremity of the humerus; almost all the hand was in a state of slough. The wadding-dressing was applied; the sloughs are now allowed to become eliminated under the cotton, and as the hand is not disturbed to be dressed, the fracture can be kept in a state of immovability.

A child had had five of its fingers crushed by a garden-roller, it was dressed in like manner; separation of the mangled parts was allowed to take place uninterfered with, and it has preserved five very useful stumps.

In these cases, the dressing must sometimes be a little modified, since we have not now to do with regular clean cut wounds, like those made in an amputation. A driver stopping a runaway horse and car, had his foot mangled,

or rather the sole of the foot stripped bare. The limb was varicose. The first day he lost a good deal of blood; next day it had to be dressed afresh, then two days after the same process repeated; finally it was left on for eight days; at present his state is satisfactory.

In another case might be noticed a little phlegmon which had been opened under the wadding. A youth, of seventeen years of age, had had a cut finger. At the end of some days, acute pains caused the removal of the dressing, there was a little phlegmon on the back of the hand. It was incised; then the dressing was re-applied. It was left on for twenty-six days; when it was undone scarce a trace of the incision could be found. The walls of the abscess had adhered together without secreting any more pus; it had become a linear cicatrix. Except the coachman, who is under treatment, all the patients that we have quoted are well or nearly so. Among the wounded more recently arrived, we must particularise one who had a wound of the elbow-joint. At St. Denis, the stroke of a Prussian sabre, had cleft the olecranon. Brought to St. Denis he was at once put under the wadding treatment. On the sixth day, his temperature was only 32° (Centigrade), he suffered a little, however, because his bandage had got loose. It is a curious and noteworthy fact which has often been pointed out to us in M. Guérin's wards, it is sufficient to put on a new bandage very tightly over the old one, with or without a new layer of wadding, as needs be; the pains cease at once. This last case was complicated with many other sabre cuts among others a scalp wound, which quite explained the *malaise* of the patient.

It is not alone to recent wounds that the wadding is applied at St. Louis. We saw a man suffering from an enormous varicose ulcer with gangrenous edges; he was sent to M. Guérin by one of the hospital physicians to have the leg amputated. M. Guérin had it dressed with wadding; to-day the wound looks healthy and is contracting; the cure may be completed by epidernic grafting according to M. Reverdin's procedure, and the patient will preserve his limb.

Such are the most interesting of the cases that we have observed at St. Louis; we do not repeat the method of applying the dressing which is precisely the same as for amputation.\* We only publish these facts to give an idea of the happy manner in which M. Guérin multiplies the application of his dressing. We have carefully examined the dressings, and could not perceive that they gave out any notable bad odour; † they are done with most minute care by M. Guérin, as well as by his pupils. One of the interns, M. Hervey, who occupies himself assiduously in applying this method, has been kind enough to furnish us with the figures, and some of the notes which have served for the compilation of our articles; when showing us the patients in the wards, he pointed out to us how necessary it was to keep up close surveillance, not to let any flow of pus escape our notice, to replace the wadding, tighten the rollers, &c., all of which must be done carefully.

Since our last article, capital operations have been rare. We must say that the figure of nineteen amputation cases cured for the month of June has kept up.

Among the new operation cases is one of a man whose foot was crushed by a machine, and whose thigh was amputated the day after the accident occurred, 15th Aug. The man (aged thirty years) got up on the twenty-sixth day, and walked about with the dressing on.

In many hospitals these experiments are being prosecuted, and with favourable results. However, it may be useful to call attention to the necessity of following to the letter the precepts laid down by M. Guérin, if one wishes to attain the admirable results obtained by thaturgeon.

We have on our part already remarked with new ex-

\* See MEDICAL PRESS AND CIRCULAR.

† They have done so in other hospitals during the great heat of summer, owing to neglect of M. Guérin's precepts.

perimenters, some infractions of the rules laid down. For example, nowhere is such energetic compression made, as in the wards of St. Louis. At some hospitals the dressing is done in the wards. Lastly, let us point out this source of failure: we have seen in several practices, bales of wadding unrolled in the middle of the ward, remaining there for more or less time before being used. M. A. Guérin protests energetically against this practice. Is it not equivalent to knowingly collecting miasma in the apparatus which is about to be employed?

## THE SEWAGE QUESTION.

### SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XXVIII.

### AGRICULTURAL VALUE OF SEWAGE.

BARON LIEBIG, also, is of opinion that sewage is less adapted for grass crops than for any other, because of its containing more ammonia and phosphoric acid, in comparison with potash, than the plant can utilise, and that its full value can only be realised on pasture land. "Suppose," says Liebig, "that we wished to produce yearly 12 tons of grass per acre, or 4 tons of hay—What quantity of sewage would be required to furnish the material? A ton of good, but not super-excellent hay, contains 36 lbs. of nitrogen—equal to 43 lbs. of ammonia, 18 lbs. of phosphoric acid, and 31 lbs. of potash; 4 tons of hay, therefore, will abstract from each acre of land 172 lbs. of ammonia, 72 lbs. of phosphoric acid, and 124 lbs. of potash. Now, as it is a law of husbandry that the effect of all the constituents of a manure is but the effect of that one of them, which, in comparison with the wants of the plant, is present in the smallest quantity, it follows that, to obtain the 124 lbs of potash, which is the smallest proportional constituent of sewage, we must use about 2,400 tons of sewage; and this contains 547.73 lbs. of ammonia and 109.6 of phosphoric acid. There is, therefore, an excess of 375.73 lbs. of ammonia and 37.6 lbs of ammonia, which are left unutilised in the soil. The effect of this, according to Liebig, is not merely wasteful, but is actually injurious, for it clogs the soil, and at last kills the plant. It is manifest, therefore, that if potash and phosphoric acid were added to sewage, so as to bring their proportions up to the requirements of the crop, less sewage would be necessary, and greater fertility secured; and with the view of ascertaining how this may be accomplished, he gives on the one hand the percentage composition of the mineral constituents of plants, from which we can learn their mineral requirements, and, on the other, the proportions of the chief elements of ordinary manures—and thus see the means of supply:—

#### PERCENTAGE COMPOSITION OF THE ASH OF PLANTS.

|              | Potash. | Phos. Acid. | Limes, &c. | Potash to Phosphoric Acid. |
|--------------|---------|-------------|------------|----------------------------|
| Wheat ...    | 30      | 45          | 25         | 10 to 15.0                 |
| Pulse ...    | 40      | 36          | 24         | " " 8.5                    |
| Potatoes...  | 54      | 18          | 28         | " " 3.3                    |
| Cabbages ... | 42      | 20          | 38         | " " 4.8                    |
| Hay ...      | 18      | 11          | 71         | " " 6.1                    |

A similar table, but more comprehensive, is given by Messrs. Lawes and Way in their Third Report on "The Sewage of Towns" (1865, p. 35).

#### PROPORTION OF PHOSPHORIC ACID AND POTASH TO ONE OF NITROGEN IN VARIOUS PLANTS.

|                | Phosphoric Acid.    |                       |                   | Potash.             |                       |                   |
|----------------|---------------------|-----------------------|-------------------|---------------------|-----------------------|-------------------|
|                | In Corn, Roots, &c. | In Straw, Leaves, &c. | In Total Produce. | In Corn, Roots, &c. | In Straw, Leaves, &c. | In Total Produce. |
| Wheat ...      | 0.48                | 0.42                  | 0.46              | 0.28                | 1.08                  | 0.57              |
| Barley ...     | 0.40                | 0.34                  | 0.38              | 0.34                | 1.26                  | 0.60              |
| Oats ...       | 0.28                | 0.37                  | 0.30              | 0.25                | 1.55                  | 0.65              |
| Meadow hay     | —                   | —                     | 0.27              | —                   | —                     | 1.00              |
| Clover hay ... | —                   | —                     | 0.23              | —                   | —                     | 0.52              |
| Beans ...      | 0.25                | 0.46                  | 0.30              | 0.32                | 1.23                  | 0.50              |
| Mangolds ...   | 0.17                | —                     | —                 | 1.00                | —                     | —                 |
| Swedes ...     | 0.27                | 0.16                  | 0.21              | 0.82                | 0.44                  | 0.63              |
| Com. turnip    | 0.28                | 0.18                  | 0.26              | 1.60                | 0.71                  | 1.17              |
| Potatoes ...   | 0.42                | —                     | —                 | 1.23                | —                     | —                 |

And with respect to the proportions of ammonia, potash, and phosphoric acid in sewage and other manures, they are as follows:—

#### PROPORTIONS OF PHOSPHORIC ACID AND AMMONIA TO 10 POTASH IN SEWAGE, GUANO, AND ROTTEN FARMYARD DUNG.

|                              | Potash lbs. | Phos. Acid lbs. | Ammonia lbs. |
|------------------------------|-------------|-----------------|--------------|
| 193 tons of sewage yield ... | 10          | 8.8             | 44.1         |
| 2,023 lbs. of farmyard dung  | 10          | 9.0             | 14.9         |
| 1,672 lbs. of Peruvian guano | 10          | 200.5           | 142.3        |

So that if 20 tons of rotten farmyard manure be put upon an acre of land (and this is considered a good average dressing) they will yield 330 lbs. of ammonia, 200 lbs of phosphoric acid, and 220 lbs. of potash; but the quantity of sewage (1,446 tons) required to yield the same amount of ammonia would contain only 75 lbs. of potash, and but 66 lbs. of phosphoric acid; and the equivalent of guano (3,877 lbs), according to Liebig's analysis, would contain 465 lbs of phosphoric acid, and only 23 lbs of potash. While, therefore, guano is rich in phosphates and ammonia, and poor in potash, and farmyard manure is the reverse of this, sewage occupies, according to Liebig, an intermediate portion, and represents a mixture of the two—especially if a little phosphoric acid is added to it in the form of soluble superphosphate. This he illustrates in the following manner:

|                                     | Ammonia Tons. | Phos. Acid Tons. | Potash Tons. |
|-------------------------------------|---------------|------------------|--------------|
| 728,767 tons of sewage contains ... | 75            | 15               | 17           |
| 275 tons of superphosphate          | —             | 75               | —            |
| Total ...                           | 75            | 90               | 17           |
| 2,650 tons of farmyard manure ...   | 19.5          | 11.8             | 13.1         |
| 652 tons of Peruvian guano ...      | 55.5          | 78.2             | 3.9          |
| Total ...                           | 75.0          | 90.0             | 17.0         |

These are in the proportion of 845½ lbs. of superphosphate to every 1,000 tons of sewage. The chief value of sewage, therefore, according to Liebig is, that by its use, the effects of phosphates, of guano, and of stable dung are made sure and lasting, and the produce of the land raised to a maximum. On this account it should never, in his opinion, be used alone, but in conjunction with richer manures. Other agricultural chemists are not exactly of this opinion, for, according to Dr. Voelcker, when the soil itself contains the elements of fertility, sewage has no more value than so much water, and will not remunerate the farmer for the expense of its application. In the case of soils naturally poor and barren, the conditions, he says, are altogether different, for then a copious application of town sewage will produce abundant crops of grass, when nothing else will grow of any agricultural value. In commenting on these remarks of Dr. Voelcker, the editor of the *Agricultural Gazette* (Mr. Morton, who is now one of the Rivers' Pollution Commissioners), said "that the lecture of Dr. Voelcker, reported in the *Gazette* for May 31, has probably done more than anything hitherto made public to determine the vexed question of the true value of town sewage, and to dissipate many of the flattering illusions entertained upon the subject; for he appears clearly to show that town sewage is of little value as an application to arable land or for horticultural purposes." Other observers have arrived at the same conclusion, and have reported that its effects were no better than those produced by water, except that when too copiously applied it always killed the tender herbage, and produced a rank description of grass.

## Hospital Reports.

### METROPOLITAN FREE HOSPITAL.

#### *Syphilitic Liver.*

(Under the care of DR. C. R. DRYSDALE.)

(Reported by MR. WILLIAM KIPLING.)

*Previous History.*—Edward Baldwin, æt. thirty-four. Occupation, a farrier. Five years ago he had a large chancre on his penis which was followed in four weeks by a number of small red spots all over his body, he also had a very severe sore-throat at the same time so that he could scarcely swallow his saliva, and he also lost a considerable quantity of hair from his head. A year after a portion of his left ear turned blue and sloughed off, this year a small portion of his right ear was affected in the same way. Never been in good health since he got the above mentioned sore.

July 1.—*Present Attack.*—Patient complains of an aching pain over his epigastrium and right hypochondrium. When he turns over it is sometimes of a cutting character. Been sick occasionally, never vomited any blood. Has a bitter taste in his mouth in the morning and is often troubled with bilious attacks. There is a good deal of flatus on his stomach; the pain is worse after meals and is easiest at night when warmed. Has lost flesh lately, and has a peculiar sallow yellowish look. Bowels regular and a good colour. There is a patch of rupia over his loins and a shallow scar of a syphilitic character below and a little to the left of his umbilicus.

On percussion and palpation the liver is found to extend from the fifth rib above, to an inch and a half above a line drawn from the level of the umbilicus below.

Ordered Potass. iodide, gr. xx.;  
Aqua, ℥j.

Ter die sumendus.

July 4th.—The pain over epigastrium and hypochondrium is nearly gone; patient feels better; appetite good; tongue clean. Pulse, 90.

July 7th.—A little aching pain over the region of the liver; flatulence diminished; appetite greatly improved; has more colour in his lips and the sallowness is not so great. Pulse, 90, full; tongue moist and clean; no headache; not much alteration in size of liver.

July 14th.—The liver is distinctly smaller than at last report. The patient sits up a little every day; the rupial sore on back is drying up; the sclerotics are now quite white. Pulse, 72.

July 19th.—The sore on back is now healed; patient is walking about and is in good spirits. Says he feels in better health than he has been for some time; no pain or symptoms of indigestion; complexion clear.

Discharged cured.

#### *Purpura.*

CASE II.—*Previous History.*—Thomas Warren, thirteen years of age, no family history of consumption or the hæmorrhagic diathesis. Works at a butcher's. Been in pretty good health all his life with the exception of his eyes which have been bad ever since he was born, he has no eyelashes on any of the lids, and there is an opacity on the cornea of his right eye the result of strumous ophthalmia; he has a very strumous appearance.

August 23rd.—Present attack came on two weeks ago with great weakness, bleeding from the nose and mouth, and an eruption of purpuric patches all over his body.

Lying on his back patient is seen to be covered from head to foot with spots of a dark, dusky hue, especially on legs on the front of the tibia; there are very few on the face; back is covered with them.

There is a soft swelling of a strumous character commencing below the ear and extending down the posterior triangle of the neck. There is a little bleeding from the gums and inside the mouth; feels very weak; tongue pallid, slightly furred. Pulse, 96; Temperature, 102.2.

Ordered Ol. morrhux, ℥ij.;  
Tinct. ferri. perch., ℥ xv.

Ter die sumendus.

To have a good diet and plenty of vegetables.

Aug. 29th.—Bleeding from the gums has ceased; spots over body are paler, and patient seems improved since admission. Pulse, 112; temperature, 102.

Sept. 6th.—Swelling in neck been painted with iodine; the purpuric spots are paler, more like flea-bites; skin hot and dry. Temperature, 100.4; Pulse, 120. Appetite good. There are traces of appearance of eyelashes. Is still very pale and pasty.

Sept. 12th.—Spots have all disappeared except a few very pale ones on legs like little specs. Pulse, 96; temperature, 99. Enlargement of neck slightly diminished.

As the purpuric spots for which the patient was taken in are better, he was discharged, as it was thought he would be benefited by out-door exercise on account of his strumous constitution.

#### Alcohol in Disease.

PROF. N. S. DAVIS, of Chicago, has made numerous and repeated experiments on himself, and collated those of others, to show the effects of alcohol on the human system. Among those stated are its diminishing the atomic changes in the tissues of the body and the sensibility of the nervous system, and also diminishing the temperature, the strength and the power of endurance. Dr. Davis designates alcoholic drinks as anæsthetic and sedative—anæsthetic to the nervous system, and sedative to the properties of the tissues. As such they are capable of being used to fill a limited number of indications in the treatment of diseases and yet there are other well-known agents in the *matéria medica* that will answer the same purpose equally well or even better. So true does he deem this assertion, that for twenty years he has not prescribed for internal use the amount of one pint of alcoholic drinks annually, including both hospital and private practice,

### SPIRITUALISM.

It would be amusing, if it were not grievous, to observe in this boasted age of progress the lamentable ignorance and superstition that abound. No wonder that the belief in witchcraft was common in earlier times, when something worse still prevails, and the Holy Scriptures are paraphrased by deluded or deluding people, who declare they possess power to “call spirits from the vasty deep,” and that the spirits have no power to refuse to come and exhibit themselves in a position beneath that of the Merry Andrew at a fair. When, however, a Fellow of the Royal Society announces the discovery of a “psychic force,” and big volumes of Reports issue from the press, and magazines proclaim the new wonder, and heavy quarterlies condescend to review the evidence, it may be thought well for a professional paper to devote a column to the subject.

We have this week received from Messrs. Longman and Co., the publishers, a portly volume containing the Report of the Committee of the Dialectical Society on Spiritualism. Some of our readers may be aware that this Society was established on the broadest possible foundation, its members neither affirming nor denying anything, as members, but each upholding, as he thinks best, whatever views he may entertain on any subject whatever. We are credibly informed, however, that the Council of the Society was very much opposed to appointing this Committee. Some members, it would appear, believe scarcely in anything, others are ready to accept almost anything. It was easy, then, to appoint a Committee that in one sense seemed to be impartial. But it has not been easy to carry out the enquiry, and we find a complaint that the advocates of the new doctrine seemed to carry all before them. The Committee split up into six sub-committees, and the conclusions of each vary. No. 1 after forty meetings, thinks that certain noises proceed from solid substances, and are sometimes directed by intelligence. No. 2 admits the establishment of spiritualistic communications in the mode about which we have heard so much. No. 3 does not go quite so far, but confesses to having seen tables tilted in obedience to a request. No. 4 tells us that

nothing occurred worthy of recording. No. 5 attacked the redoubtable Mr. Home, who gave every assistance, but nothing took place “which could be attributed to supernatural causes.” No. 6, saw nothing but two children rock about a chess table. After this we are treated to the conclusions of the General Committee, which are as inconclusive as can well be imagined, and to the statement of evidence. We must not forget to add the dissentient statements, some of which convey the charge that the spiritualists got the enquiry too much into their own hands, as we might have expected these enthusiasts would.

The Report very aptly illustrates the heterogeneous character of the Society. What could be expected from such a committee? It is as if a committee of Christians and Atheists were invited to frame a report on the truth of the Scripture. It may be very well for the most opposed tenets to be discussed at a Society, but to ballot afterwards as to on which side the truth lies, is an idle procedure.

As to these spiritualistic *séances*, we think them worse than idle. They are positively mischievous. They go far to discourage sober, scientific enquiry. We have no objection to Mr. Crookes, or any other F.R.S. devising an experiment to put the assertions of a medium to the test. Such a plan may really bring out the truth. But we strongly protest against the notion that if the experiment fail to account for what may take place, the philosophy of the medium is therefore to be accepted. We know too well how human nature can delight in cheating, and being cheated. We have seen too many dodges to take more than a languid interest in mediumistic lore, and we feel so thoroughly with Professor Huxley on the matter, that we append his reply to the invitation sent him to assist in the inquiry.

SIR,—I regret that I am unable to accept the invitation of the Council of the Dialectical Society to co-operate with a committee for the investigation of “Spiritualism;” and for two reasons. In the first place, I have no time for such an inquiry, which would involve much trouble and (unless it were unlike all inquiries of that kind I have known) much annoyance. In the second place, I take no interest in the subject. The only case of “Spiritualism” I have had the opportunity of examining into for myself, was as gross an imposture as ever came under my notice. But supposing the phenomena to be genuine—they do not interest me. If anybody would endow me with the faculty of listening to the clatter of old women and curates in the nearest cathedral town, I should decline the privilege, having better things to do. And if the folk in the spiritual world do not talk more wisely and sensibly than their friends report them to do, I put them in the same category. The only good that I can see in a demonstration of the truth of “Spiritualism” is to furnish an additional argument against suicide. Better live a crossing-sweeper than die and be made to talk twaddle by a “medium” hired at a guinea a *séance*.—I am, Sir, &c.,

T. H. HUXLEY.

If this does not satisfy any one, we commend a perusal of the capital article on the subject in the current number of the *Quarterly Review*.

---

### CUNDURANGO.

THE announcement of a new cure for cancer was sure to excite a great interest, and to raise many expectations on the part of sufferers. We find that the confidence at first expressed seems to be abating rapidly, and that in some quarters it is even already condemned.

Our able contemporary, the *New York Medical Record*,

has not been from the first favourably disposed towards the new therapeutic pretender, and makes now a complaint that seems to us unanswerable.

It seems the State Department is disinclined to let the evidence accumulated be published. We agree with our contemporary that the investigation and the discussion of the virtues of the plant, belong to the Profession, and any concealment is a public scandal. We have nothing favourable to report of any trials in this country.

The *Record* publishes the Report of the Board of Governors of the New York Hospital to the State Department, of which it has secured a copy, and promises to give any further evidence it can procure.

The following is the Report in question :—

"The undersigned, a committee of the physicians and surgeons of the N. Y. Hospital, to whom were addressed certain packages of a remedy known as Cundurango, and claimed to be a cure for cancer, which had been sent from the Department of State in Washington to the Governors of the Hospital, and by them referred to the Medical Officers of the Hospital for trial, report :—

"That they distributed it among medical gentlemen of known capacity, to be administered by them according to directions accompanying the remedy, to patients under their charge suffering from cancer.

"From the written reports of these gentlemen the committee derive the following particulars, which they herewith submit :

"Dr. J. Dole, of Amherst, Mass., writes :—' June 22nd. His patient was a lady, forty-four years of age, mother of two sons. She had a hard, nodulated flattened cancer, involving the entire right mamma, which was adherent to the ribs, and covered a space of between three and four inches in diameter. From the surface there oozed a thin serous discharge. In the right axilla and supraclavicular region there were hard nodules evidently involving the axillary plexus of nerves and causing severe neuralgic pains extending down the arm. In the left mamma, which retained its form, though wasted, a hard, small nodule was felt. The disease had existed about two years and a half, and first developed itself locally in the right mamma soon after a severe blow on the part. For several years prior to the appearance of the cancer her health had been deteriorated by repeated hemorrhages from hemorrhoids. These had been successfully operated on by ligation about three months before commencing the Cundurango treatment.'

"Dr. Dole writes : 'I can say but little concerning the action of cundurango, as most of the effects were negative. It was administered in the form of a decoction (each dose representing what virtue could be thus extracted from exactly eighty grains of the powdered wood and bark), given twice a day, at eight o'clock a.m. and p.m., two hours after food. You will remember Mrs. W.'s condition when she left New York. The following changes took place : 1st. The third day of administration she reported (unasked) entire freedom from pain in the nodule under the nipple of the *left* breast, which, up to that time, had been for weeks the seat of severe and constant lancinating pain. This pain never returned. 2nd. On the fifth day healthy granulations appeared at the edges of the sore, finally springing up in all parts of it, the whole surculo presenting from that time a normal appearance : the right arm could be moved with more freedom. 3rd. The constitutional symptoms not modified ; appetite, pulse, respiration, and temperature remaining the same. Bowels somewhat more constipated, but not markedly so. The neuralgic pains continued with unabated severity during the whole time of administration, and were quieted by McMunn's Elixir Opii, given p. r. n. I noticed also the odour of perspiration, which was very marked and peculiar, like the odour emitted from an uncut cadaver ; odour of urine strong, but not unlike that of urine in many acute diseases. After each dose of

the medicine (at an interval of from fifteen to thirty minutes) a peculiar restlessness showed itself which continued from two to three hours.

"*Summary.*—Medicine continued seventeen days—a decoction representing 160 grains by weight per day ; total relief of pain in left breast ; improvement in character of sore, and increase in power of right arm, with partial restoration of power of motion without pain. Noticeable change in odour of perspiration, and a peculiar restlessness following the administration of dose. Should say I witnessed this phenomenon fifteen times. Constitutional effect *nil*. The appetite gradually failed, but not more rapidly than could be accounted for by the discontinuance of tonics. In conclusion, Doctor, allow me to say, I am very sceptical concerning the power of this remedy, but there was a curious coincidence between its administration and the modification of local symptoms. I tried to guard against any hasty conclusions in the matter. I have hope enough in its power to try it again in a case where the constitutional power was greater than in the case of Mrs. W. The exhibition was stopped eight days before her death ; but I was absent, and cannot report on the effects of the change. Dr. B. assures me that the sore continued healthy until death.'

"Dr. F. A. Burrall, of New York, reports, 'July 10th, I have been using an infusion of cundurango prepared according to the officinal formula in a case of rodent ulcer, or, as the disease is termed by C. S. Moore, F.R.C.S., rodent cancer. The ulceration occupied the helix and posterior portion of the right external ear, and the adjacent part of the scalp. The patient had previously been using a lotion of a watery solution of carbolic acid, tannin, and glycerine, and the lotion was continued. During the six weeks which were necessary for a trial of the cundurango the ulceration progressed slowly but steadily. No marked general symptoms accompanied the use of the medicine.'

"Dr. H. B. Sands, of New York, writes 'July, 15th, My experience in the treatment of cancer by the cundurango plant is confined to a single case in which the remedy was administered according to the prescribed directions for a fortnight. The patient, a lady residing in this city, suffers from cancer of the rectum, and at the time she began to take the medicine referred to the disease was already far advanced, causing a pretty close stricture of the gut. It was noticed that during the brief period the cundurango was used the cancerous growth increased with greater rapidity than at any previous time, and several large nodules of the morbid deposit appeared in the pelvis, causing a protrusion of the abdominal walls. The patient is still living, and intends to make another trial of the remedy whenever it can be obtained.'

"In conclusion, the committee do not consider the exaggerated pretensions claimed for the cundurango plant as a cure for cancer substantiated by the results of the trials herein reported. They would not, however, discourage more extensive and thorough trials of its virtues, especially if such trials could be prosecuted without enlisting popular sympathy, which has already been prematurely evoked, and that without at all promoting the attainment of truth.

"Gurdon Buck, M.D.,  
"T. M. Markoe, M.D., vice } Com. of Physicians  
"W. H. Draper, M.D., absent } and Surgeons,  
"New York, July 26th, 1871." } N. Y. Hospital.

## Notes on Current Topics.

### The Froth and the Dregs.

UNDER the above somewhat peculiar title a *brochure* on the Reorganisation of the British Army has recently appeared. The two principal subjects discussed in that

work are the manner in which our army should be officered and the description of soldiers we ought not to trust to for the purposes of an army. In so far as professional interests are concerned, it is of no matter whether our army be officered by the froth, cream, or that substantial part of English society represented by the clear good liquor underneath, yet above the lower stratum or dregs. What is wanted is the simple result of efficiency, nor need we concern ourselves by considering whether the army ought, as a profession, to be a whit more aristocratic or a whit less so than any other profession. But we as representatives of the medical profession are anxious to know what really is to be said in the selection of suitable materials for the ranks of the army, and the effect for good or evil of the system of administration in force to maintain that efficiency. Sir Edward Sullivan, the author of the pamphlet in question, quotes a good deal of what has of late years been adduced by Army Surgeons against the plan of engaging large numbers of young immature lads as recruits, but omits to notice the condemnation of the same system by surgeons and generals long before it became the fashion to pay much attention to questions of public health. He very opportunely reminds his readers that during the late war some 700,000 of the German soldiers were between the ages of 20 and 27, while the 300,000 men of the Landwehr behind them were from 27 to 32—all the men of both classes being carefully selected as to their physical fitness to undergo the fatigues of service. We all know what happened when such men came in collision with the young relatively feeble recruits who had rapidly to be drafted into the ranks of the French army. The latter were little able to bear the fatigues of long harassing marches, and on the field of battle were swept away like flies.

A considerable part of the pamphlet is devoted to the unsuitability of young lads as soldiers for service in the Tropics, and especially in India. It is almost a pity that the author passes by without remark the argument so often made use of by the imperfectly informed, that inasmuch as the rate of mortality among young soldiers is much under that of the elder, therefore the efficiency of the former must be greater than that of the latter; for had he done so he would have doubtless told how fallacious is the argument, inasmuch as in active service it does not need that a man should die to become more effective, for he who is sick or weak, requiring carriage and men to attend him, is for military purposes more non-efficient than if he were dead. In the one case he is a veritable burthen, in the other he is simply buried. No doubt there is one respect in which young men are more suitable for soldiers than their elders, and that is the comparative readiness with which they can be drilled and disciplined. In order, however, that both should be carried out it is necessary that the recruits should be kept as it were in a military nursery until they have passed twenty years of age, a recourse which, under existing conditions, becomes utterly impossible. Another evil which arises from the necessity of enlisting very young lads is that discipline is relaxed. The recruits instead of having as their early *mentors* elderly and experienced non-commissioned officers have only lads a little older than themselves. The result is that acts of thoughtlessness and mere boyish stupidity are magnified into crimes; punishment causes hatred and ill-feeling, a career is marred, the lad is soured, and in a very few years afterwards he returns to civil life with a knowledge

of arms and discontented against "the Powers that be." He is ready to take the part played by the National Guards of France should the opportunity arise for so doing.

Next to the *materiel* of the army our author finds fault with the administration. "In the Crimea, in India, everywhere in fact where British troops have been engaged, it was the *civil* administration of the army, not the fighting part that was at fault." "We may be officially informed that we have an army of 60,000 or 100,000 men, or whatever it may be, ready at any moment to go to any part of the world, but every man of sense knows that if this army is short of field guns, or artillery, and transport horses, of a sufficient commissariat, and *medical staff*, it cannot be called an efficient army." With regard to the single item of *medical staff* the history of all wars since that in America, it included, has shown the insufficiency of means to provide for more than a portion of the wounded. Had it not been for the action of philanthropic associations it becomes a matter for very serious consideration by what means the Government of this country may be able to render eleemosynary assistance unnecessary, and fulfil the moral obligation it is under to fully provide for all its soldiers, who, in the performance of their duty, in peace or in war, fall by the stroke of sickness or by their enemies.

#### Health of Dublin.

IN the Dublin Registration District, the births registered during the week ending 14th October, amounted to 140. The average number in the corresponding week of the years 1864 to 1870 inclusive, was 152. The deaths registered during the week were 183. The average number in the corresponding week of the previous seven years was 150. Seven deaths from small-pox were registered during the week, the respective dates of death being August 20, September 12, September 23, October 9, October 10, September 23, and September 26. Ten deaths resulted from fever, viz., 4 from typhus, 3 from typhoid or enteric, and a like number from simple continued fever. Six deaths were caused by whooping-cough, and 3 by scarlet fever. Diarrhœa proved fatal in 13 instances. Fifteen deaths were referred to convulsions. Twenty persons died from bronchitis. Two deaths were ascribed to apoplexy, and 4 to paralysis. Five deaths were caused by heart disease. Nephria or Bright's disease, kidney disease unspecified, and inflammation of the kidneys, caused 1 death each. Nineteen persons fell victims to phthisis or pulmonary consumption, 10 to hydrocephalus or water on the brain, and 4 to mesenteric disease. Cancer killed 3 persons. Four deaths resulted from accidental causes. Fifty-nine of the persons whose deaths were registered during the week were under 5 years of age, and 44 were aged 60 years and upwards, including a woman stated to have attained the age of 98 years.

#### The Waste of Wine on Mere Paupers.

WE recommend the following observations of the *Pall Mall Gazette* to the consideration of the Cork Board of Guardians:

"The West Derby Liverpool guardians have, it is stated, under consideration, the large allowance of stimulants ordered by parish doctors to paupers on the sick list. A girl of about fifteen years of age has, it is alleged, been

consuming stimulants to the extent of 9s. worth in seven days. The doctor who is attending the case, on the other hand, maintains that stimulants were absolutely necessary; and in a letter of explanation adds, 'the guardians will be glad to learn the girl is rapidly recovering.' Supposing that the girl has actually drunk nine shillings' worth of stimulants in seven days, after all it only amounts to the cost of two bottles of adulterated port wine, whereas it is a well-known fact that in some cases of illness a bottle of wine a day is necessary to keep body and soul together. If the doctor is not worthy of confidence, let him be dismissed. But so long as he is entrusted with the care of the sick, surely he and not Poor-law guardians, ought to be the judge of what is necessary for his patients. Rigid economy may have great claims to respect, but it is not the paramount object of importance in life, and it has lately acquired a most objectionable practice of asserting its claims to overrule Christianity, prudence, and common-sense, and to take up a position it has no right whatever to occupy."

#### Dr. Pascal on the "Medical Times and Gazette" and on Dr. Virchow's reproaches against France.

IN the *Mouvement Médical* the able editor, Dr. Pascal, utters a touching and noble remonstrance to Dr. Virchow for some words which that gentleman has thought fit to speak against the medical men of Paris, because, forsooth, they were supposed not to have been sufficiently opposed to the recent detestable war. Many of us remember how shocked we all were by the expressions made use of by the editor of the *Medical Times and Gazette* last summer, when that editor spoke with supreme contempt of the leaders of the liberal party on the Continent. M. Pascal, too, has been as much shocked as ourselves at the ill-toned diatribe uttered by that spasmodically violent journal; and, with sorrow and anguish of heart, protests against the insults of medical men who should have been more generous than to speak bitter words against their brethren of France in the hour of their sorrow and humiliation. Well for us it is that our City of London contained noble hearts who, in the hour of adversity, remembered the divine injunction to "love one another," and thus gave a sublime lesson to medical writers, whose mission it surely should be to appeal to our feelings of common humanity, rather than to side with the bigots and rowdies of Germany or France in inciting to national hatred. We are fully aware of the intense sorrow and chagrin entertained by men of science in Paris, when they hear such unfeeling remarks from men who ought to be better and to feel more nobly than these. But, let us assure our respected *confrères* of Paris and M. Pascal among the rest that there is a warm heart beating in the breast of the English medical body for the brethren of Velpeau, Trousseau, Ricord, Louis, Andral, and a hundred worthies of our noble calling; and that we at any rate can never forget what Europe owes to France in science, in art and literature. Perchance, these few words of ours may touch the hearts of Dr. Virchow and the other more insolent and less excusable offenders and we may live to hear them both cry for forgiveness, to their brethren of France, Germany, and Britain. Virchow, indeed, from a recent paragraph from his pen seems to have relented. The writer, who belonging to neither nation interposed with calumny and insult, and thereby degraded his calling and misrepresented his profession so far as we know has at present evinced no regret. Still, while there is life there is hope.

#### Poisoning and Pilfering Wholesale and Retail.

SUCH is the title of a shilling pamphlet in verse, by the author of "John Jerningham's Journal," and devoted to the exposure and condemnation of the sophistication of food that disgraces our age. Those who have read "John Jerningham" need no recommendation other than the authorship to read this. Those who have not should do so forthwith.

#### The Medical Society of London.

AT the opening of the ninety-ninth session of this, the oldest medical society in London, the President (Dr. Andrew Clark) gave an address to a very large meeting. In the course of his speech Dr. Clark gave some very interesting particulars of the last illness of Dr. Salter. After this a paper was read by Dr. Richardson "On the Possibility of Destroying Animals intended for Human Consumption without the Infliction of Pain." He described two modes of painless death—viz., by electricity, and by the inhalation of narcotic vapours, and explained a plan by which a light narcotic vapour could be rendered immediately effective for the object in view. Mr John Gay then read a paper on "Crural Venosity." The discussion on Mr. Gay's paper was postponed until last Monday evening.

#### Fever in Liverpool.

RELAPSING fever has broken out in some of the impoverished and dirty parts of Liverpool, and we hear that the health of the town is otherwise not satisfactory.

#### The London Medical Schools.

THE number of medical students at the different hospitals and medical schools in the metropolis exceeds 1,450, a larger number than has been known for some years past. About 460 are new entries. Guy's, which last year headed the list with 110 fresh men, has this year fallen to 86. University College now takes the lead with 90 new entries; St. Bartholomew's has 81; St. Thomas's, 58; King's College, 43; and the London Hospital, 29. The entries at the other schools vary from 20 to 10 at each. The great falling off this year at Guy's is thought by some to be caused by the establishment of St. Thomas's in its permanent home.

#### The Inhalation of Oxygen Gas in Cholera.

DR. HEYWOOD, of New York, writes to the *Medical Record* to say that several years ago he called attention to the use of this remedy in Asiatic cholera. Letters were addressed to the various Boards of Health, and to many of his friends in the profession, but nothing came of it, except the opinion, pretty unanimously expressed, that it would very likely be found to be a good thing, and that it had been suggested before. At that time there were various difficulties in the way of its application, but now these have been lessened. In the large cities oxygen gas is carried about for every-day consumption, and can be obtained as easily as air. In smaller places the necessary salts and the simple apparatus for their decomposition can be obtained by an express order. The value of the agent for the relief of some of the symptoms of this direful disease cannot, he thinks, be questioned. No one

can doubt that the cold congestive stage will be mitigated, and if care be taken not to heighten the subsequent ebrile reaction, the mortality will assuredly be lessened.

### Aconitine.

MM. GREHANT and DUQUESNEL recently presented to the French Academy of Sciences a memoir on aconitine, which M. Duquesnel has succeeded in extracting from *Aconitum Napellus* in the form of rhomboid or hexagonal plates. M. Duquesnel treated the root of the *Aconitum* with concentrated alcohol, with the addition of 1 per cent. of tartaric acid; the excess of alcohol was afterwards removed by distillation, and the residue diluted with water in order to precipitate the fatty and resinous matters. The aqueous solution of tartrate of aconitine was treated with an alkaline bicarbonate in order to set the alkaloid at liberty, this latter being very slightly soluble in water. It dissolves in ether, which, on evaporation, leaves it in the crystalline condition. M. Duquesnel assigns to it the formula  $C_{26}H_{44}NO_2$ . Aconitine is very slightly soluble in water, very soluble in alcohol, ether, benzine, and chloroform. It is not volatile, and commences to decompose about  $130^{\circ}$  C. Its reaction is feebly alkaline. It combines with acids to form crystallisable salts; the author cites the acetate as presenting abundant crystals. Phosphoric acid, tannin, potassium iodide and iodate, and the double mercury and potassium iodate, produce the ordinary reactions on organic alkaloids.

### The Origin of Cholera.

DR. JOHN C. PETERS, of New York, in a valuable paper on the "Origin and Travels of Asiatic Cholera" (*New York Medical Journal*), says we are driven back on British India as the only country in the world having the unenviable reputation of being the abode of endemic cholera; for none can deny the fact that it is endemic in Calcutta, where the lowest number of deaths from it per year, since 1841, was 2,502, the highest 6,417. In Madras the lowest number of deaths in one year was 574, the highest 3,635; in Bombay the deaths from cholera, among from 6,000 to 21,000 white troops, have varied from 4 in one year to 1,085, *i. e.*, from 1840 to 1868; among 26,000 to 47,000 native troops, from 4 to 190 per year; among 5,000 to 8,000 prisoners, from 1 to 203 per year.

### An Enormous Specimen of Odontolithus.

J. J. VINCENT, D.D.S., of Amherst, Mass., recently exhibited a specimen of tartar, or odontolithus, which measured three-and-a-half inches in length and half an inch in breadth; the base was nearly half an inch thick. The patient, wife of a clergyman, aged thirty-five years, positively stated that she had always been in the habit of brushing her teeth inside and outside three times daily. The specimen was removed from the coronæ of the teeth of the lower jaw—*viz.*, the incisors, bicuspid, and canines. A species of infusoria, *Denticula hominis*, was found in it.

THE *Boston Medical and Surgical Journal* has brought out a "Students' Number." We are glad to see that in addition to the usual details it contains an Introductory Address, and much other interesting matter.

### The Proposed Cholera Hospitals.

At a meeting of the St. Pancras Guardians last week Mr. Salter called attention to the alarming increase of taxation to be apprehended by the order given by the Local Government Board to the Asylum Board to construct hospitals for the reception of cholera patients. An expenditure of at least £100,000 was expected, and when it was recollected that the Asylum Board had already involved the metropolis in a debt of £464,000, it was high time that the representatives of the ratepayers should interfere.

### Qualifications for Irish County Infirmaries.

THE recent election to the County Kerry Infirmary at Tralee, to which we alluded last week, has been well understood brought by Dr. Lalor under the notice of the Council of the Royal College of Surgeons in Ireland, with a view to obtaining their statement of opinion as to the eligibility of a Fellow elected into the College during the Year of Grace to hold the office.

As we explained last week, Dr. Lalor, as a Licentiate of the College, contemplates contesting the validity of the election in the Queen's Bench, and maintains that the Fellowship conferred during the Year of Grace, is not equivalent in value to the letters testimonial. The clause of the College charter which provides for the election of Fellows by examination, specially provides, as we have pointed out, that the Fellowship thus conferred shall carry with it all the privileges of a Licentiate; but the clause which gave power to create Fellows without examination during the Year of Grace, does not contain any such proviso, and the omission may be read as against the possession of such privileges by elected Fellows. The first clause, however, of the Charter, confers upon the "Fellows who shall be elected, or admitted by election, all the rights, privileges, and immunities which might be possessed by Members of the College." The Council has, we believe, decided to take counsel's opinion on the point, but feels itself unable to express any feeling thereon itself.

The questions to be decided are: 1. Do the words "letters testimonial" in the Act of Parliament bar the election of Fellows to county infirmaries, despite the clauses of the Charter which make a Fellowship equivalent to Licentiate. 2. If not, do the "Year of Grace" Fellows participate in these privileges?

### Cheap Pride.

WE have all heard of the old lady who was proud of her aristocracy because "her aunt was an alderman, and her grandmother a justice of the peace," and we know that Scotchmen are proud of the bagpipes, and their want of "breaks." A new development of pride has been manifested in Londonderry, where we find from a local union report, that "Mr. Alexander was proud to say that the district with which he was connected had a medical officer who would visit for a mere nominal charge."

It is charged that Irishmen are poor and proud, but it appears the Derry people are certainly not the former, for Mr. Alexander recounts the cases of three of his own labourers, who earn over £50 a-year each. He thinks they and their betters are very poor, and ought to be pauper applicants for medical relief. We rather suspect that if an increase of salary to the medical officer were talked of, Mr. Alexander would be the first to pronounce the doctor rich

enough on his £70 a-year. If we are to choose between the medical officer who attends well-to-do people on red tickets without protest, and the medical officer who visits the same class "at a mere nominal charge," we much prefer the former.

### Obscene Swindling Tricks.

WE noticed last week a threat of legal proceedings by a quack, named Sylvester, resident in Willesden, against the *Irish Builder*, for publishing his name in a quack directory. Anent this virtuously indignant rascal, the following letter appears in the "*Standard*":—

"SIR,—Perhaps you will think it worth while to acquaint the public with an interesting little arrangement which has been carried on in this quiet suburb for some months past. Last May I was appointed curate of this parish, and as I possess a medical qualification which appeared in the announcement of my licence to the curacy, I cannot help connecting that circumstance with the fact that about the same time the following advertisement began to appear in different papers:—

"Health a Boon for All—Those suffering from depression of spirits, confusion, headache, blushing, groundless fears, unfitness for business or study, failure of sight and memory, fear of insanity, may hear of means of removing their sufferings by addressing F. Sylvester, Esq., P. C. Curate, Church-end, Willesden, Middlesex, who has cured a great number of his parishioners, by means adopted. Enclose stamped envelope."

"I only found this out a few days ago, and knowing that there was no such gentleman residing in the neighborhood, I made inquiries at the post-office with a view to disclaiming for myself the credit of having so generously attended to the bodily ailments of my numerous parishioners.

"Judge of my surprise on learning that a gentleman was in the habit of calling twice a week in a carriage and pair, for a harvest of letters in answer to the above advertisement; of which letters, I had the satisfaction of counting some twenty-seven, which had accumulated towards the next instalment.

"Leaving your readers to make their own comments on the sagacity of the advertiser, and the astuteness of his confiding correspondents,—I am Sir, &c.

"H. COURTENAY ATWOOL, M.A., M.D."

No communication could bring home to the public comprehension with more force, the success of obscene swindling as a means of livelihood than this letter. Political economy not unusually degenerates into political humbug, and the nonsense that is talked of in the name of liberty of the subject about the right of the free Briton to be made a fool of, if cunning impostors can effect that object, has been carried too far when it permits so scandalous a system to exist.

A BRANCH of the Anti-Compulsory Vaccination League has been formed at Cork.

DR. MIDDLETON O'MALLEY KNOTT has been appointed to the post of Surgeon in the Mayo County Infirmary, lately held by his lamented father, Dr. Knott, of Castlebar.

THE Recorder of Newcastle has shown us that strikes cost the country something more than money, trouble, ill-will, and loss of trade. The privations which the artisans have to endure leave their inevitable record in the mortality amongst them, and the last Newcastle strike brought the death-rate up from 26 per 1,000 to 40.

It is said that Nélaton will come to settle in London.

DR. JOHN WILLIAM OGLE is the new Inspector of Anatomy for the provinces.

It is probable that a Medical Officer of Health will be appointed for Keighley.

THREE medical men are candidates for the coronership of Northumberland, now vacant.

MISS TRAFFORD SOUTHWELL is about to build a cottage hospital for Wisbeach.

THE Italian Medical Congress in Rome is, we are told by a correspondent, quite a success.

THE Hampstead Hospital inquiry is still going on. We do not propose to enter upon any criticisms so long as the matter is *sub judice*.

YESTERDAY week the Pathological Society of London commenced its sittings for the season with a good attendance, presided over by Mr. T. Holmes, V.P.

LAST week there were only four deaths from small-pox and one from cholera in Paris. The improved sanitary arrangements having sensibly reduced the mortality of the city.

WE regret to hear that Mr. Holmes Coote, Senior Surgeon to St. Bartholomew's Hospital, has for the present been compelled to relinquish his duties at that institution, on account of failing health.

THE French Government is at the present time engaged in a laudable endeavour to ameliorate the hygienic condition of the soldier. The diet, barrack accommodation, and other matters connected with his somewhat monotonous existence, will undergo a strict scrutiny.

THE first lecture of the eighth course on Experimental and Practical Medicine will be delivered by Dr. Richardson (of London) at 12 Hinde street, W., on the last day of the present month. The present series will commence with a lecture on "The Science and Art of Embalming the Dead."

ON the 22nd of November next the Senate of the Queen's University will proceed to elect examiners in the following subjects, and at the salaries stated, to hold office between the 31st March, 1872, and 1873:—Medicine, £100; Surgery, £100; Midwifery, and the Diseases of Women and Children, £75; Materia Medica, £75; Medical Jurisprudence, £75.

THE next meeting of the Pharmaceutical Society of Great Britain will be held on November 1st, 1871, at eight o'clock. The following papers will be read:—"A New Excipient for Pills," by Mr. J. B. Barnes; "Examination of Small Cinchona Trees grown in India," by Mr. J. E. Howard, F.L.S., &c.; "Pharmacy in North Germany and Austria," by Mr. T. Greenish, F.C.S.; "The Substitution of Proportional Numbers for Specified Weights and Measures in the Description of Processes in the Pharmacopœia," by Professor Redwood.

## SCOTLAND.

WILLIAM WALKER, Esq., has been elected President of the Royal College of Surgeons of Edinburgh.

THE question of lady medical students has again been brought before the public, the subject of complaint at present being an interdict issued by the Medical Faculty of the University of Edinburgh, prohibiting females appearing for the preliminary examinations on the 17th and 18th. The females having laid before the Dean of the Medical Faculty the opinion of counsel favourable to their views, the dean under the circumstances, declined to take the responsibility of refusing their admission to the examinations. No female has yet been allowed to matriculate in the University, in consequence of instructions issued by the principal, Sir Alexander Grant, Bart.

DR. GILLESPIE has been appointed one of the consulting surgeons to the Edinburgh Royal Infirmary.

## Literature.

## SIR J. SIMPSON'S WORKS.

THE late renowned Professor of Midwifery in the University of Edinburgh was a prolific writer. The wonder to many who knew him best is how he found time, amongst multifarious engagements, to prepare for the press as much as he did. Not a few of his papers were of rather a fugitive character. Nevertheless, we should be glad to see every one collected, and annotated by competent editors. Messrs. Adam and Charles Black deserve the thanks of the Profession for bringing out his works in a collected form.\* We have the first volume before us, and two others are announced as shortly to appear. This volume contains the substance of the late Professor's Course of Lectures on Midwifery, and is thus, so to say, complete in itself, though it also forms one of the series of the collected works. Dr. Watt Black lived for five years with Sir J. Simpson, as his assistant, and has therefore been requested to edit this volume. We venture to say that the selection is fully justified by the manner in which he has executed the work. Some of the papers in this volume appeared in the two volumes of "Obstetric Memoirs and Contributions," edited in 1856 by Drs. Priestly and Storer.

The "Clinical Lectures," issued in a contemporary three or four years later, and of which we have a most vivid recollection, will appear in a separate volume, under the editorship of Dr. Simpson, who has succeeded to the Chair of his great relative, and will, we doubt not, bestow his best care upon them. The present baronet, Sir Walter Simpson, is to edit the volume on "Anæsthesia and Hospitalism," to which we look forward with lively interest. We see no announcement respecting "Acupressure." It is also well known that Sir J. Simpson was the author of many papers of a non-professional nature, and it would be, in our opinion, a most desirable thing that they also should be republished in the same form, so that all who pleased might possess a handsome library edition like this, of the complete works of one of the most remarkable of modern physicians. Such an edition would be a worthy memorial of the illustrious baronet, and we hope to see our suggestion carried out. In the present volume we observe several papers have been omitted, but we cannot but wish that everything that fell from Simpson's pen could be collected under suitable editorship, such as that of this volume.

\* "Selected Obstetrical and Gynecological Works of the late Sir J. Y. Simpson, Bart., M.D., D.C.L." Edited by J. Watt Black, M.D., M.A. Edinburgh. A. and C. Black. 1871.

We have not much to say of the lecture notes which form the first part of the work, but to all of his old pupils they will, we are sure, call up more distinctly than anything the massive-headed, intellectual teacher to whom humanity owes so much. Part II. gives his papers on "Pregnancy; Part III., those on "The Fœtus and its Appendages;" Part IV., those on "Parturition;" Part V., those on "The Puerperal State;" and Part VI., those on "The Non-puerperal Diseases of Women." Of course, all of these papers are more or less known to the Profession. We shall not be expected to criticise them. Suffice it to record our satisfaction at seeing them in this form, and mentioning one or two that we have been particularly pleased to see again. The first three relate much to diagnosis. They are on "The Sound," "The Exploring Needle," and "Artificial Anæsthesia for Facilitating Diagnosis." On treatment there are many papers. Those on "Polypi" and "Carcinoma," and on "Ovarian Disease" perhaps excite the most intense interest, while the last three papers, brief as they are, extending only from page 817 to the end, are both curious and important; they are on "Infra-mammary Pains," "Spurious Pregnancy," and "The Alleged Infecundity of Females born Co-twins with Males.

## THE MEDICAL JURISPRUDENCE OF INSANITY.

OUR jurists have not, as a body, neglected the subject of insanity, yet we think there was room for such a work as that produced by Mr. Balfour Browne,\* who desired apparently to write for the lawyer and medical man alike a more systematic treatise than any intended. Such a work should assist in reconciling some of the differences between the two professions, and we are free to confess that Mr. Browne, as a barrister, has displayed an impartiality for which he deserves full credit. We are of opinion, however, that to produce a perfect guide—and our author will perhaps be the first to admit that he may not have attained perfection—requires a medical as much as a legal author. We should be very glad to see the joint production of an able physician such as Dr. Crichton Browne, to whom our author makes acknowledgment of some assistance, and a barrister of the learning and talent of Mr. Balfour Browne, to whom we are indebted for this work, by far the fairest towards our Profession, and the most complete from one point of view that has yet appeared.

Our readers will, we doubt not, remember some able original communications by Mr. Browne in the columns of the MEDICAL PRESS AND CIRCULAR. These have been re-written, and incorporated in their proper place in the volume before us. We shall, therefore, make no quotations, as our subscribers are acquainted with Mr. Browne's style, but proceed to state what the book contains, remarking that it is fortified by recent cases and decisions, and from a legal point of view is perhaps unassailable.

We could have wished to see the chapter on "Aphasia" more extended, but its brevity is no doubt due to the fact that *legally* aphasia is of less importance than *medically*, while our interest in it is naturally far higher than that of a lawyer. This is a good illustration of what we mean when we speak of a double authority for a work on this subject, though it is but right to add that such a book as we have ventured to suggest could not be compressed into the compass of that before us. The chapters on "Lucid Intervals" and "Feigned Insanity" are full of interest, and that on "The Admissibility of the Evidence of the Insane," bears marks of the author's careful study. The brief chapter on "The Prognosis of Insanity" contains some very smart hits, with which we fully sympathise, but which will, we expect, draw upon the author's devoted head the thunder of a whole regiment of statisticians, mad-doctors, and would-be philosophers, who may feel that his shafts have gone home, and that they cannot reply in kind.

\* "The Medical Jurisprudence of Insanity." By J. H. Balfour Browne, Esq., Barrister-at-law. London: A. and J. Churchill.

The concluding chapter is on "The Examination of Persons supposed to be of Unsound Mind," and it contains many shrewd hints put in a forcible manner, which we can advise every one to read before undertaking the important duty to which it refers. Mr. Browne gives a number of illustrations of the carelessness of medical men in filling up certificates. Speaking from several years' special experience, we can say that he has not exaggerated this negligence, and it is one which really reflects some discredit upon the Profession. The distinction between fact and opinion ought to be easy to every medical man, and no one ought to be unable to follow exactly the directions that are printed for his guidance on every form of certificate. We may, however, say in defence that the certificates in question are arranged in a very inconvenient mode, and the trivialities for which they are frequently returned to the writer are most vexatious. It would be far better to have them revised in such a manner as to render them more easy to fill up, and more intelligible when complete. We have had occasion to instruct many medical students as to filling up these certificates in the course of lectures on medical jurisprudence, and have invariably found that they regarded them as very complicated. The fact that hundreds are invalidated by trivial matters substantiates the complaint. Busy general practitioners fill them up in a hurry. We may safely assert that it is a duty they do not wish to fulfil, and the least that could be done would be to simplify it as far as possible.

The responsibility of certifying to a patient's unsoundness of the mind is considerable, but is not so great in the opinion of most people as going into the witness-box to testify the same thing. Of course the facts and the opinions are the same, but the medical man, with the fullest determination to speak merely the truth, may not unfrequently feel strange on account of his position being one that he is not often called upon to occupy.

It is a fact, too, that counsel have on many occasions abused their office by endeavouring to confuse a medical witness in a most unwarrantable manner. This tendency is perhaps passing by, and we are glad to find that our author speaks in a way which shows that he fully appreciates the position of the medical witness. He gives very sound advice upon his conduct, and we doubt not would himself examine and cross-examine alike in a most proper and gentlemanly way. His book closes with good advice to the witness, and our notice we end with the assurance that we fully appreciate it.

## Transactions of Societies.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, OCT. 13TH, 1871.

DR. W. W. GULL, F.R.S., President, in the Chair.

Some introductory remarks were made by the President on this the first meeting of the Session.

DR. BAUMLER read a paper on  
PARTIAL AND GENERAL IDIOPATHIC PERICARDITIS,  
in which he endeavoured to prove that the white or milky spot on the surface of the heart frequently met with at post-mortem examinations has a clinical history of very transient acute pericarditis. He adduced in support of this proposition two cases, in which an acute illness, coming on with dyspnoea, with pain behind the sternum, radiating upwards to the larynx, the left shoulder, and towards the left ear, and with slight febrile disturbance, was accompanied by a characteristic pericardial friction sound, lasting, like the other symptoms, only for two or three days. In a third case, where the onset had been more gradual, the friction sound was heard over a larger area; and there was also some distension of the pericardium by fluid; yet the whole attack was mild and lasted only a fortnight. Such intermediate forms link the very slight cases to the more serious

ones, which more generally come under observation. Cases of idiopathic pericarditis being of rare occurrence, Dr. Baumler appended the history of three other cases of this kind which had come under his observation. The three patients had been little girls from eight to ten years of age, and the pericarditis had come on in so insidious a manner that they had walked about with the pericardium full of effusion. One of them died; the two others recovered, one entirely, the other with valvular disease remaining. With regard to treatment, Dr. Baumler particularly recommended the application of ice to the cardiac region, especially for its influence in reducing the number of the heart's contractions and in relieving pain.

The PRESIDENT remarked that, among other points of interest in connection with this subject, it has been a matter of doubt as to whether genuine pericarditis, *per se*, ever causes pain, and that some so-called cases of the disease had proved to be cases of pleurisy, the friction sound being due to a pleuritic rubbing immediately over the pericardium.

DR. DOUGLAS POWELL asked Dr. Baumler how the treatment of ice-bags could be reconciled with the intermittent application of linseed and mustard poultices.

DR. C. T. WILLIAMS asked for particulars as to the influence of ice-bags on the pulse and heart.

DR. BAUMLER replied that, according to his knowledge and belief, the application of ice-bags acts antiphlogistically, reducing both pulse and temperature, and that the poultices were used, in the absence of other remedial agents, because in an empirical way they relieved pain.

MR. NUNN read a paper on

#### LUPUS ERYTHEMATOSUS.

This disease, known also as superficial lupus, was believed by Mr. Nunn to be essentially an inflammatory atrophy of the cutis, limiting itself to that structure, and thus distinguished from lupus exedens, which was capable apparently of destroying indiscriminately every structure. Two cases of lupus erythematosus were reported, in which the family history afforded no clue to the nature of the disease; and, in contrast, one case of lupus exedens, in which an hereditary syphilitic taint was, with almost complete certainty, to be traced. The first two cases had been treated for years before coming under Mr. Nunn's care with mercury, iodine, arsenic, &c. The first patient, a male, aged thirty-four, had (October, 1870) suffered during thirty-two years, the second during twenty-one years, with lupus erythematosus of the cheek. The bromo-iodine waters of the Woodhall Spa, in doses of a wine-glassful three times a day, were given, and a tablespoonful of lemon-juice in a tumblerful of milk every morning. In the first case, the gums being spongy, a solution of chloride of zinc (one grain to the ounce of water) was ordered to be applied to them. This case was, to all appearances, cured at the end of six months. The second patient was still continuing the treatment with advantage, having only commenced it in May last. The case of lupus exedens had been in the Middlesex Hospital under the care of the late Mr. Moore, and was now an inmate of the Hospital for Incurables, at Putney.

DR. ALTHAUS thought the plan of giving large doses of these salts was too commonly practised, and that smaller quantities would, when used therapeutically, be quite as beneficial; and Dr. Gull remarked that this disease was so much an opprobrium to the physician that all hints as to its treatment were welcome and valuable.

MR. G. LAWSON related the particulars of a

#### CASE OF LARGE MELANOTIC TUMOUR OF THE EYE,

which had burst through the sclerotic and had extended into the orbit. He first excised the globe and then freely applied the chloride of zinc paste for the purpose of destroying all the tissues within the orbital cavity, and thus effectually to get rid of all the cancer germs with which those structures are in such cases generally infiltrated. The operation was performed in July of this year, and the patient was now progressing favourably towards recovery. All the tissues within the orbit sloughed, and large portions of the bony cavity have exfoliated. Mr. Lawson remarked, that when the diagnosis of melanotic tumour within the eye is made at a very early stage of the disease, the simple removal of the eye is frequently sufficient. He quoted the case of a patient in whom he had been able to recognise the tumour by the ophthalmoscope when it was scarcely the size of a pea. He removed the eye, and now nearly three years have elapsed and there has been no recurrence of the disease in the orbit.

MR. CAMPBELL DE MORGAN, after referring to the case under discussion, said that the occurrence of epileptiform seizures after operations in which these caustics were applied was not uncommon. The fits usually come on a few hours after the operation, and recur every twenty minutes, with marked diminution in the power of the pulse. The most severe case of the kind that had come under his care eventually did well; and in reply to Dr. Buzzard it was elicited that no recurrence of the epilepsy took place after convalescence from the operation.

The PRESIDENT believed cancer to be a local disease, but thought the question ripe for discussion.

MR. LAWSON said that the tumour, when growing within the eye, is black, but becomes colourless after it has burst through the sclerotic coat.

MR. NUNN was disposed to question the trustworthiness of statistics of operation in affording positive evidence as to prolongation of life.

MR. HENRY LEE did not operate to cure, but to remove a hideous deformity.

MR. DE MORGAN, MR. ARNOTT and MR. LAWSON contended that cancer was a local malady.

## SOCIAL SCIENCE CONGRESS AT LEEDS.

OCTOBER 8TH.

### THE HABITS OF THE LABOURING CLASSES IN THE RURAL DISTRICTS.

DR. ACLAND (Oxford) read a paper on "The Sanitary Care of Villages and Cottages." He said that in well-ordered modern towns the poor had the cleansing and scavenging of the surroundings of their homes done for them. In a village or an isolated cottage, the labourer, often ill-fed, always hard-worked, must either perform this duty himself or it was left undone. The condition of the closet accommodation in some villages and cottages was virtually inconsistent with a sense of domestic order, and was often productive of most injurious effects on the health of the family. The water was poisoned. Fevers are originated, and permanent ill-health was engendered through recurring bowel attacks. A generally untidy and miserable state of the surroundings became the habit of the family. The children grew up with these associations, having no other home-standard of decency. Many facts to show the extreme gravity of this matter in our rural districts—grave from its effects on the health of individuals—more grave, from the effect on the moral nature by engendering indifference, and on the intellectual powers by breeding ignorance and consequent false opinions on common matters. The remedy seemed to be, that, *mutatis mutandis*, the same sanitary care should be bestowed on a cottage in the country as on a house in a town. In the case of a well-ordered town the community provided water for its members, and removed their refuse for them. Not so in a village, probably, in many districts, every cottage, or every other cottage, has its well, and there being, of course, no sewers, its own cesspool. The expense and risk from want of organisation were both multiplied. It might be said that our scattered populations were not worth the care, or that, if worth the care, then the supervision would in practice be too costly; so that the care of hamlets and villages was either impracticable or visionary. Issue might be joined on both these objections. The rural populations cast into the towns either a strong, decent, manly, people, or an enfeebled progeny, brought up unwisely. The immigration of the rural into the urban population was noticed on the Continent also, and was, in fact, a necessary law of modern civilisation, depending on varying causes. The case of the villages was, therefore, apart from special humanity towards the individuals, truly a national question. The great measure of last session, which undertook to harmonise into one whole all existing powers bearing on the public health, and which assigned to one minister the duty of consolidating and improving the law, wherever improvement and consolidation are needed, virtually decided the question as to what executive is to guide. With respect to the purely rural districts, the great powers of the Public Health Acts resided with vestries and guardians. In many cases, therefore, they were indirectly in the hands of the very class of persons who required guidance and help. Herein lay a great part of the strength of the Local Government Board. It enlisted in the

cause of public health, understood in the widest sense every ratepayer who voted on matters of parish organisation, and the medical men of the poor. The cottages in rural districts should be scavenged by the community, and not by the occupier. There were two ways in which this could be done: one, in villages where regular sewers and water-supply can be provided and maintained; another, in isolated cottages, where, from expense, these methods were practically inapplicable. In Broad Clyst the former has been lately tried. In Stanton Harcourt, in Oxfordshire, the latter plan had been put in operation on the dry earth system, by Colonel Harcourt, the son and successor to the venerable and scientific Canon Harcourt, owner of Nuneham. An inspector, paid by Colonel Harcourt, went weekly to the cottages on the estate to examine and report on the condition of the closets, and if they were in a bad state he removed the manure as a fine, because then the owners lost it from their gardens. The first of these methods could not pay interest on the outlay, and could only be done by persons who had capital at their command. Neither the parish nor the union could be called on to contribute to a purely local improvement, except on the principle that a great landowner must have good houses for those who till his land, the outlay being calculated as for the whole of his property; or on that principle which made the whole country pay some apparently metropolitan charges because they are part of the imperial expenditure. On the whole, there was no doubt that an arrangement could be made in every rural district, whereby the poor labourer might have the necessary surroundings of his home kept in order for him, like his fellow-artisan in town. It would conduce to his health and energy, and it would be both just and politic, since all who believe in the existence of national health and national morality feel that the agricultural labourers deserve the utmost care of the nation.

OCTOBER 7TH.

### SANITARY QUESTIONS.

MR. E. CHADWICK, C.B., read a paper on the "Sanitary Influences of Town Pavement." Amongst the evils arising from bad pavement, he named the escape of gases, the baneful effects of vibration on the system, caused by unevenness; the loosening of the joints of the pipes, and the affording of direct means for the propagation of disease. In places where self-cleansing house drains and sewers had been brought into good action, and where the death-rates had been reduced, but where some amount of typhoid and foul-air diseases yet lurked, these had been very much confined to those streets where the surface was unpaved and badly cleansed, and the sub-soil sodden with foul matter. The Val de Travers pavement had realised more than was expected in the amendment of town pavements. It was to be wished, however, that the material were more abundant, that it might be obtained cheaper.

DR. BISCHOFF, of Glasgow, read a paper on the "Purification of Water and Sewage by Sponge Iron." The powers of metallic iron to purify impure water had been known for a long time. By sponge iron, he meant iron which had been produced in reverberatory furnaces by reducing an oxide without fusion. The surface was naturally greater than that of iron in any other form, and it was to be expected that its purifying action must be proportionately increased. Sponge iron could be made at a moderate cost in almost unlimited quantities from burnt ores after the copper had been extracted by the so-called chloralisation process. Water which was not thoroughly bad, but of doubtful character, might be thoroughly purified by filtering through sponge iron.

MR. T. J. DYKE sent a paper "On the modes of dealing with Outbreaks of Pestilential Fevers, sanctioned by the Health Authorities of Merthyr Tydvil."

DR. FERGUS (Glasgow) read a paper on the "Production of Disease by Excremental Pollution." The appearance of diphtheria as a disease in this country, was probably owing to our carelessness in the disposal of excreta. Typhoid fever, also (killing annually from 15,000 to 18,000), was produced by either contaminated air or water, the results of excremental pollution. He exhibited soil pipes from water-closets which were corroded by sewer gas, and which had caused typhoid fever. The principal grounds for believing that this state of the pipes arose from sewer gas, he

said, were that the perforations were generally in the upper surface of the pipes, and from within; also, that in ventilated pipes, the corrosive action was much slower than in pipes where the gas was not allowed to escape at the top. This state of pipes was not easily detected, as plumbers looked for liquid leakage, which would not take place, as the perforations were on the upper surface.

MR. W. H. MICHAEL said the difficulty was not how to get rid of the solid human excreta, nor even of the fluid excreta; but the great difficulty was the large amount of house-refuse which was sent into the drains. This house-refuse was acknowledged to be the difficulty, and that which, if putrescent, caused the whole of the mischief. This fluid must be dealt with; it must be taken away; it must get into the drains; and, if not dealt with, it would inevitably become mischievous and propagate disease.

OCTOBER 9TH.

#### THE HEALTH OF OPERATIVES IN FACTORIES AND WORKSHOPS.

IN the absence of Mr. Godwin, the chair was taken by Mr. Rawlinson, C.E. The special question for discussion was, "What are the best means of promoting the Health of Operatives in Factories and Workshops?"

The first paper was read by Dr. J. H. STALLARD, who said the question for discussion was narrowed down to what took place in the workshop. He maintained that the death-rate and the kind of disease existing proved that the air in many cases was impure. A sufficient supply of air was capable of reducing the deaths resulting from pulmonary disease; and this fact he illustrated by a reference to improvements in barracks to secure ventilation. Having contrasted the conditions under which the town artisan and the agricultural labourer pursued their callings, he contended that man was made to live in the open air, and not in a box. People who were employed in towns were obliged to be fed more expensively than they would be if isolated in cottages in the country districts. There was no doubt that a more healthy race could be produced by a less amount of expensive food than could be produced by the very best food, in large aggregations in towns and large establishments. The real stamina of the country came from the agricultural element, and that was due principally to the fact that the labourers worked wholly in the open air. Factories and workshops should be so constructed as to assimilate the condition, as near as possible, to that of the open air, with provision only for protection against rain and violent draughts. This was all that was really required. All ventilation proceeded from the supposition that a certain amount of air was sufficient, whereas the true supply required was only to be obtained by living in the air. He exhibited a diagram of an improved method of ventilating hospitals, public buildings and dwelling-houses; and said that if it were wanted to place workshops in free contact with the open air, the principle of numerous small openings must be adopted, and the laws of diffusion and connection must be relied on for a sufficient and complete interchange. That was, apartments must be protected from the direct pressure of the wind and yet a large surface must be provided with which the communication with the outer air should be free. The laws of diffusion and connection were sufficient to ensure interchange even in the stillest atmosphere, if only they had sufficient opportunity for acting; and the problem was thus reduced to the question as to the largest surface of room-sides, which might be perforated by innumerable small openings so placed as to be free from any outside pressure of the wind. It would be expensive and difficult, and useless, to perforate the floor; but if the ceiling were perforated and protected from rain, and exposed nowhere to the direct pressure of the wind, the workroom would be placed in free, complete, and immediate contact with the outside air, and the principle of slow diffusion would have full play. No great volume of cold air could possibly be driven down on any side of the apartment, whilst the freest exit was provided for the exhalations from the lungs and body, and for any unwholesome products of the manufacture. There was no disturbance in the atmosphere of the room sufficient to interfere with the natural rising of the vitiated products to the ceiling; and in the plan he had proposed, there was nothing to prevent the escape of those products into the air-chamber, from which they were at once carried away by the horizontal current passing through. The arrangement was simple. Every room should be provided with a double ceiling, the space between being in free communication with the outer air on all

sides. The top ceiling was either the floor of the room above, or the roof; the lower ceiling was made of finely-perforated zinc or oiled paper. The air-chamber should be large enough to admit of being swept out from time to time, and the sides might be made of perforated bricks of various colours and shapes. This plan did not interfere with the employment of opposite windows and ordinary means of warming rooms. The sole object was to maintain the principle of living in the open air, under all conditions, whether in winter or summer, day or night. The principle, in his judgment, was as necessary in a bed-room as in a drawing-room, and as necessary in a factory as in a hospital. It had been ignored by architects since the Roman era; but he would observe that the courts of the Pompeian house were but a more open arrangement than the one proposed. He believed that the best means of improving the health of operatives in factories and workshops would be to place them in direct communication with the open air by the plan proposed.

The REV. B. LAMPART (London) said the principle and theory put forward by Dr. Stallard were correct, but he argued that the variations of temperature, especially at night, were such that the plan would be attended with danger in some cases.

MR. P. H. HOLLAND held that all the benefits sought by Dr. Stallard could be got without the sacrifices proposed. As the best means of ventilating, he recommended warming the air with the waste heat before it is given off.

MR. RAWLINSON, C.E., said there was no artificial remedy, there was no fine-drawn remedy of flues or valves, or other means of that class that would give fresh air in the abundance that would appear to be necessary for health. He had been sent out by the Government to the army in the Crimea, where there was certainly room for an experiment upon the grandest scale. Our troops in the Crimea had suffered in the three months during the dreadful winter of 1854-5 at the rate of 700 per 1,000, or 70 per cent. There was starvation of various kinds—from want of necessary provisions, and from actual exposure to the elements. In the first instance, a number of huts were sent out from England, at very great cost, in lieu of tents; but these wooden houses had no sooner been inhabited than they became fever-dens and pests of the very worst kind. No instructions were given to provide isolation of each hut from the sub-soil, and to provide ventilation. The side walls were eight feet high, and the roof was covered with patent felt, which was waterproof; but unfortunately, it was air-proof too; and there being no arrangement for any ventilation at the floor, and the huts being arranged for twenty-five men, one-half of the occupants had fever. A most striking condition of affairs was found out in comparing the position of the 79th with that of the 42nd Regiment. Lord Clyde had gone with him for the first inspection, and he asked to be told the difference between the two regiments, there being very little fever amongst the 42nd, and much in the 79th. Upon investigation, he found that the encampment was on a steep mountain side, the greater part being oolitic limestone and dry, but there was a broad band of clay underneath. The 79th Regiment was on the band of clay, and the persons erecting the huts had excavated a level place into the bank of the hill-side, and consequently at the back it was three to five feet in height, sloping down at the sides; and, no provision being made to keep the earth from the sides of the huts, they were like inverted bell-receivers, with the men inside and the damp soaking in under the floor. The 42nd, on the other hand, were on the rock, and they had been compelled to raise a false floor for the huts. He advised the shifting of the regiment, and, from the time that it was shifted, the new type of disease ceased, and only the men had to recover who were originally down. The huts, however, on this band of clay were not taken down. The quarter-master forgot that they were empty. The 32nd Regiment came from India and was quartered in them, and when they had been there fourteen days there were thirty-two cases of cholera. The huts were still kept there, and a brigade of artillery having been sent into them, within thirteen or fourteen days there were thirty or forty dead with cholera. As to day and night atmosphere, people in this country were not so much afraid of ventilation as those on the Continent. On the Continent—in France, in Germany, in Italy—there was nothing of which people were so much afraid as open windows; and the common remark if an open window were seen at night was, "There is some fool of an Englishman living in that house." There was something of a bugbear in what was said of the difference of temperature between night and day. If patients

could be kept out of a direct draught, and well clothed with the bed-clothes, no harm need be apprehended. As Miss Nightingale said, what could we have but night air; and how could we injure patients by night air? There was either the atmosphere around, or an artificial atmosphere of a most abominable character. Travellers out in the East had a scorching sun on the sandy plains of Arabia, and the largest rivers were frozen over at midnight; but it was never heard that travellers there suffered from the variation of temperature; and he himself had been in a country where, during the day, the temperature in the sun exceeded 120 degrees. He had to march, with his coat off, and was perspiring from every pore. He had no shelter at night but a thin piece of cotton, and yet he saw one inch of ice on the river at night. He had always been considered a very delicate man; and although he did not say that patients could be submitted to a difference of temperature such as that, yet the human constitution would wonderfully adapt itself to circumstances if it had fresh air. Pure, uncontaminated air must be let in and out in profusion, or we could not have that health which was necessary.

MR. G. H. L. RICKARDS read a paper on the "Advantages of the Factory Legislation that has taken place from time to time." The benefits of the Factory Acts to the working classes he cited as follows:—1. Improved physical education; 2. Entire freedom from some forms of disease; 3. Increased protection from accidents; 4. Protection from excessive work; 5. Improved sanitary condition of factories; and 6. The education of all children under thirteen years of age. By the Act passed two months ago, the whole of the workshops of the country had been placed under the jurisdiction of the factory inspectors. In 1867, when it was necessary to add a large number of various trades to those already under the provisions of the Factory Acts, an Act was also passed placing all the workshops under the supervision of the factory inspectors. Their chief duties would be to prevent overwork, to see to the sanitary condition of the workpeople, and to attend to the education of all children under thirteen years of age. In this way, the whole industrial classes obtained the advantage of the supervision provided by the Legislature through the exertions of the factory inspectors.

#### THE WASTE OF WATER.

MR. P. H. HOLLAND read a paper on "A Cheap mode of preventing Waste of Water when continuously supplied."

## Correspondence.

### PERSONAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On coming back to town my attention has been drawn to a paragraph in the PRESS, which insinuates two or three things, viz., as to my making personal attacks upon brother professionals, not writing sense, and heaping abuse on the proprietor because it was deemed advisable to refuse insertion to communications. I beg to deny that this latter was the real cause of my remonstrance with the editor; that it is totally untrue that I have ever made an attack on a brother professional, that I did not sign my name to it in fair debate; and as to this, and not writing sense, I am quite willing to leave it to the Profession to judge, rather than the warped imagination of the PRESS sub-editors.

I am, &c.,  
Sackville street, Oct. 6. CHARLES KIDD, M.D.

[We publish this letter lest occasion might be given to its author to say we feared to do so. Dr. Kidd is good enough to construe our remarks for us. We have only to say that his translation of our meaning is literal, and we adhere to our original statements.—ED. MED. PRESS & CIRC.]

Two young English ladies residing in Paris (says *Galigiani*), the Misses Isabella and Mélanie Winch, have just received from Count de Flavigny, President of the International Society for affording Relief to the Sick and Wounded in the late war, the bronze cross of merit, accompanied by a diploma setting forth the useful services rendered by them during the siege, principally at Montrouge, both in the ambulances and on the field of battle.

## Medical News.

**Royal College of Physicians of London.**—At an extraordinary meeting of the College on Monday last, Edward John Waring, M.D., St. And., 49 Clifton gardens, Maida vale, was admitted Fellow; and the following gentlemen having conformed to the bye-laws and regulations, and passed the required examinations, were granted Licenses to practise physic including therein the practice of medicine, surgery and midwifery:—Cornelius Biddle, M.R.C.S., 26 Queen's road, Dalston; Henry Davies, M.R.C.S., Pentrepoth, Morriston, Swansea; Wilson Eager, M.R.C.S., Bethlehem Hospital, S.E.; Frederic H. Edmonds, M.R.C.S., University College Hospital; Simon Halford Hobley, M.R.C.S., 20 Queen's crescent, Haverstock Hill, N.W.; Frank E. Newington, M.R.C.S., 1 Evering Villas, Amhurst road, Hackney; John Scully, M.R.C.S., Middlesex Hospital; William Stamford, M.R.C.S., Tunbridge; John Howell Thomas, London Hospital; William Barrow Wall, University College Hospital; John G. U. West, M.R.C.S., University College Hospital; John Burdett Wilby, M.R.C.S., Leicester. The following candidates having passed in medicine and midwifery will receive the College Licence on their obtaining qualifications in Surgery recognised by the College:—George Bland, St. Bartholomew's Hospital; and Thomas Davies Harries, Guy's Hospital.

**Apothecaries' Hall of London.**—At a Court of Examiners on the 19th instant, the following gentlemen were admitted Licentiates of the Society of Apothecaries—viz., Messrs. Richard John Carey, of Northampton; Joseph Hindon, of Creydon; Edmund Robinson, of Leeds; and William Barrow Wall, of Wedmore, Somersetshire.

**Cholera in the East.**—Recent advices state that cholera is slightly on the increase. Isolated cases have occurred in several parts of the city of Constantinople. In the week ending September 26th there had been thirty cases, nineteen of which terminated fatally. Quarantine is now enforced at all the Ottoman ports. Cholera, however, is reported to have ceased in Brussa.

**West Kent Medico-Chirurgical Society.**—At a meeting on the 13th inst., Dr. Purvis in the chair, the following gentlemen were elected officers for the ensuing session:—President: Mr. J. M. Burton. Vice-presidents: Dr. Edward Clapton and Mr. A. Roper. Council: Dr. John Anderson, Dr. W. Carr, Dr. Samuel Giles, Dr. R. Gooding, Mr. W. Lockhart, Mr. Charles Nind, and Dr. John C. Thorowgood. Treasurer: Dr. Prior Purvis. Secretary: Mr. John Prior Purvis. Librarian: Mr. G. G. Bothwell. The newly elected president, Mr. J. M. Burton, delivered an inaugural address.

The Academy of Medicine of Turin has announced a new prize, under the name of the Premio Bianco, which will be given in the beginning of 1873. The value is 1,000 lire; the subject is "Matrimonial Hygiene." All manuscripts to be sent in before December 31st, 1872.

**Royal College of Surgeons of England.**—At a meeting of the Council on the 19th inst., the following gentleman was admitted a Fellow of the College: Robert B. Travers, M.R.C.S., (1841), Rostellan, Co. Cork.

**The Leeds Sanitary Exhibition.**—In our notice last week, we omitted to mention an improved elastic infant's belt, exhibited by Mrs. Baines, a lady well known for her laudable and philanthropic efforts to promote by simple sanitary appliances and suggestions the well-being of her poorer fellow creatures. This elastic belt, we are informed, is the only article of clothing exhibited this year, and if it but suggests some improvements in dress on hygienic principles to those who have the manufacture of those articles, a very desirable reform will have been attained.

**Newly-built Houses.**—A vast deal of ill-health, to say nothing worse, results from the too early occupation of newly-built houses. In the suburban districts of London, and of many of our large towns, small houses by the thousand are planted on the ground, often on heaps of unwholesome deposits placed there to fill up hollows whence brick, earth, or sand may have been removed, are finished with pauseless rapidity, and, all reeking as they are, receive a family often before the workmen have left. The danger involved was recognised long ago. An ancient foreign proverb says, as to a

new house, "The first year for my enemy, the second for my friend, the third for myself." The speculative builder of to-day too often cares for neither friend nor enemy. The houses, like certain historic razors, are made to sell. To turn a penny is his sole object, and the buyer must look out for himself. Alas! for such a state of feeling. It unfortunately prevails in modern society to a much greater extent than is consistent with the right condition of public health, giving that word its full meaning.—*Builder.*

**A New Light.**—A French chemist has discovered a light as superior to gas as gas was superior to its predecessor, oil. An opportunity will soon be afforded of beholding this beautiful, clear, and healthy light, as the officials of the Crystal Palace Company have laid pipes, placed gasometers in position, and in a few days will illuminate their crystal fountains and rare works of art with the new Oxyhydric light; and in order that the public may have ocular demonstration of its vast superiority over gas, the lights will alternate, and then the dull yellow haze of the flickering gas lamp will become doubly so in the steady, bright light, emanating from the other, which is so intense that it causes the flame of gas to cast a shadow itself on the wall it is intended to illuminate. This new light can be obtained at a much lower rate than gas; and it is not only brilliant and clear, but healthy. Above the issue aperture in the ordinary gas lamp, when lighted, there is a dark space, surrounded by the flame, with sparkling atoms floating upwards, many of which escape unconsumed, and pollute the surrounding air, much to the injury of eyes and lungs, while others that enter the flame, in passing through it are only partially consumed, and in the shape of smoke or dust escape into the surrounding atmosphere, to the detriment of pictures, ceilings, or gilt frames, &c. Nothing of all this occurs with the new light.—*Mechanics' Magazine.*

## Gleanings.

### Statistics of the Medical Profession in the United States.

DR. J. M. TONER, of Washington, D. C. says in the *Boston Medical and Surgical Journal*:—I have completed a synopsis of the list of all the physicians of the United States who have paid the special internal revenue tax of ten dollars on their profession for the year ending April 30, 1871. The list, as it is at present, may be considered a complete "Medical Register of the United State." It is arranged by States and Territories, and has the post-office address, with a prefix to each physician's name showing the theory or system of medicine which he practices. The profession is divided and classified under the following heads: regular physicians, homœopathic, hydropathic, eclectic, and miscellaneous and unknown. The latter includes all those irregulars who could not be placed in either of the classes named, as well as many supposed to be regular, but of whom we have not sufficient facts to warrant placing their names in that class.

|  |        |
|--|--------|
| Whole number of physicians of all classes, | 49,793 |
| “ “ regular physicians,                    | 39,070 |
| “ “ homœopathic physicians,                | 2,961  |
| “ “ hydropathic,                           | 133    |
| “ “ eclectic,                              | 2,860  |
| Miscellaneous and unknown,                 | 4,774  |

This gives a ratio of 16·8 physicians to one homœopath in the whole number, and 13·1 regular physicians to one homœopath. Estimating the population of the United States in round numbers at 39,000,000, we have one regular physician to every one thousand of the population. The proportion of homœopathic physicians to the whole population would be about one in every 13,000. This is certainly less than we had supposed.

### Case of Chronic Nasal Catarrh.

DR. NORTON FOLSOM, Physician to the New York Dispensary, writes to the *Medical Gazette*:—

The following case is reported mainly for the purpose of calling attention to the convenience of the apparatus employed in treatment.

Mr. B—, æt. thirty-five, a fine singer, free, so far as known from any constitutional taint, had suffered for over a year from an offensive purulent discharge from the nose, which frequently formed crusts as large as the thumb, so hard and so closely adherent as to be disengaged with considerable diffi-

culty. The voice was so much affected that singing had been almost entirely relinquished, and the factor of the discharge interfered with his social relations.

Rhinoscopic and anterior nasal examination showed the mucous membrane generally engorged, eroded in patches, covered with viscid muco-purulent secretion, and the lower and posterior part of the vomer entirely gone.

The nasal douche had previously been tried without benefit, but its use was resumed with a solution of permanganate of potassa, together with the application of spray of alum and of tanno-glycerine. After a few weeks, the only material improvement being the diminution of factor, the following line of treatment (mainly that lately recommended by Drs. Sass and Lincoln at the Med. Lib. and Jour. Assn.) was adopted. The whole nasal cavity being strongly illuminated with the concave mirror, with the use of the rhinoscopic mirror behind, and with a nasal speculum, contrived for the purpose, in front, the cavity was entirely freed from crusts and secretion by forceps and probes, and by the patient's own efforts with a basin of water. A solution of nitrate of silver (gr. 40-60 ad unc.) was then applied in the form of spray, from front and rear, to every part of the cavity, and the thoroughness of its action verified by examination. This was repeated at intervals of a few days for about ten weeks, the improvement being constant, and after an interval of a month, during which he grew worse, it was resumed for six weeks, when it was entirely abandoned, after about twenty applications in all, there being no offensive discharge, no formation of crusts, and the mucous membrane presenting a healthy pink appearance throughout. The voice was entirely restored. There has been no relapse during the year which has ensued.

The spray was applied with the ordinary hand-ball apparatus, the fluid being contained in a test-tube held in the hand, and the issue of the spray being instantly and completely controlled by the thumb compressing the rubber tube where it joins the atomizer. For the posterior nares the upward-jet atomizer was used, a small piece of hard rubber being fitted to the tube just in front of the orifice, projecting upward about  $\frac{3}{8}$  inch, forming a palate hook.

The addition of a few drops of *eau de Cologne* to the spray solution rendered it less disagreeable, and the after-taste was sensibly diminished by gargling with salt and water. The nostrils and upper lip were protected with an unguent.

The nasal speculum contrived for the exigencies of this case is made by coiling a piece of German silver wire at its middle, (as in an ordinary eyelid retractor), so that the ends tend to spring apart; the extremities being then bent nearly at a right angle, are curled up into blades about  $1\frac{1}{4}$  inches long and  $\frac{3}{8}$  inch wide, which *flange apart* a little at the tips, which are to be introduced into the nostril. The degree of expansion is limited by a screw. The whole instrument is gilded. It is made by Messrs. Tiemann and Co. A useful addition is a piece of flexible wire attached to the ring of the instrument, which can be made to rest on the lip or cheek of the patient, and tilt or prop the nostril up horizontally. This leaves both hands free for manipulation, while the light is thrown in from the mirror on the forehead. In this way nearly every part of the naso-pharyngeal cavity can be reached, and accumulations, even upon the posterior wall of the pharynx be detached through the anterior nares.

### On the Significance of the Liver-fat, and of the Fatty Liver for the Healthy and Diseased Body. By Dr. O. Naumann, Leipzig.

THE *Glasgow Medical Journal* thus notices this paper in *Reichert and Du Bois-Reymond's Archiv*. The author of this paper has already pointed out in another place that the fat obtained from the liver is much more readily absorbed by the skin than other fat; it is as much as from four to seven times more readily absorbed. The liver-fat is further much more easily assimilated by the intestines, and also very much more oxidisable. These facts are intimately connected with the long established therapeutic value of liver oil. In the present paper he lays down as a fundamental proposition, that in all the cases which he has examined, the fat from the liver was much easier oxidised than that from the other parts of the body, as the heart, the kidney, and the subcutaneous adipose tissue; and with this view he has examined the liver of fishes, pigs, ducks, the fatty liver after phosphorus poisoning, the fatty liver in tuberculosis, and the pathological fatty liver in ducks. His method of testing the degree of oxidisability was by shaking the oil obtained in a test-tube, with a dilute solu-

tion of permanganate of potash, the degree of the decolorisation of the fluid indicating the degree of oxidation. From the universality of this fact, the author deduces that one great function of the liver is to prepare for the organism an easily assimilable—that is to say, an easily oxidisable fat; and that it does this chiefly by producing some unknown alteration of ordinary fat, but may also in part produce fat from albuminous principles. Taking another view of the question, the deduction is confirmed by the fact that, as a general rule, in the various classes of animals, the size and activity of the liver, but especially its proportions of fat, is in inverse proportion to the perfection of the function of respiration. Thus, in fishes the liver is unusually large; in birds proportionally very small. Then, again, the liver is formed very early in the embryo, and all through fetal life, the greater part of the blood passing into the foetus passes through the liver before entering the general circulation, whereas, after birth, when the respiratory organs come into action, the absorbed fat passes in the form of chyle through the ductus thoracicus into the circulation without being first sent through the liver. The liver in fishes and amphibians, as well as in the embryo of higher animals, is therefore to be looked on as to some extent an accessory organ to the organs of respiration. And now in respect to the pathological fatty liver. It has been already stated that in it the fat presents the same peculiarity as in the normal liver, and the author regards the change as rather a physiological than a pathological one. The object of the increase in size and in the production of fat in the liver is to supply to the diseased organism readily assimilable fat, so that the large fatty liver has for the patient a similar significance as the normal liver has for the sound person. In the case of phthisis pulmonalis, which gives us the most frequent examples of fatty liver, it is easy to understand how the large fatty liver should act as in fishes, and the foetus as an accessory organ to the partially disabled lungs. But in the other class of cases where the lungs are not affected but where, as in chronic emaciating diseases, the activity of the functions in general is diminished, it is easy to understand how a supply of easily oxidisable matter would be a great desideratum to the weakened organism. The fact is thus explained how it happens that in the case of fatty liver the subcutaneous adipose tissue is generally deficient, the cause being that the fat is absorbed, but cannot be used till modified by the liver, which organ at a given time contains a large amount undergoing this process of modification. There is only one exception to this view, that, namely, of the fatty liver of the drunkard, where the fat is stored up in the liver, its place being in great part taken up by the easily oxidisable alcohols. In all the other cases the fatty liver is not a depôt for the fat of the body, as it has been generally considered, but an active agent modifying the fat which it contains.

#### Opium Growing in Trinidad.

A GENTLEMAN near Nashville, it is stated, has for the last three years been engaged in raising the poppy for the manufacture of opium. Owing to the lateness of the planting, the inferior nature of the soil, the crop of 1870 failed, and to obviate this difficulty seed was obtained from Calcutta and Smyrna at a cost in gold of 4.50 dols. an ounce. The crop of this year, it is announced, will yield from fifty to seventy-five pounds of opium per acre. Another gentleman in Tennessee, also extensively engaged in the cultivation of the poppy, reports a similar success. The best opium poppy-seeds were obtained from Smyrna, planted in good land, and cultivated like cotton. When the capsules of the poppy are ready to scarify, an incision is made on one side and in twenty-four hours the juice, which has the appearance and consistency of thick cream, is scraped off. The opposite sides of the capsules are then scarified and the operation is repeated. The juice of the poppy, a few hours after it is gathered, turns a dark purple colour, which grows gradually darker until the peculiar opium colour is reached.

#### Pertussis Curable by Local Treatment.

DR. W. F. McNUTT, M.D., M.R.C.S.E., says in the *Boston Medical and Surgical Journal*:—

It had not occurred to me that the local treatment of pertussis was not in more general use until I observed, in the *Boston Medical and Surgical Journal* for April 20, 1871, an article by Dr. Caldwell, of Brooklyn, N. Y., headed, "A New and Successful Treatment of Pertussis." He says: "Believing Niemeyer's view of the pathology of this disease, 'that

whooping-cough is a catarrh of the respiratory mucous membrane, combined with intense hyperæsthesia of the air passages,' I made my medication directly to the parts affected." His medications were made by the spray atomizer.

My own experience, as well as that of Dr. R. T. Maxwell, my partner, is that most cases of whooping-cough can be cured by local treatment, and that one need only try the treatment to be convinced of the fact. But why attribute the above pathology of this disease to Niemeyer, or call the local treatment of this disease new? While local treatment for whooping-cough is by no means new, local treatment by means of the spray atomizer may be comparatively new.

As early as 1849, Dr. E. Watson, of Glasgow, recommended a strong solution of nitrate of silver to the interior of the larynx as a very successful method of treating pertussis. (*Edin. Monthly Journal and Retrospect*, December 1849, p. 1290.) Twenty-five years ago, Prof. J. B. Wood refers to inhalations as being in use for the treatment of whooping cough. He says: "The substances used in this way among others, have been cherry-laurel-water, camphor, tar, benzoin, galbanum, nitrous acid, vapours, &c. It has been many years since it was noticed that children suffering with whooping cough who lived in the neighbourhood of gas-works were rapidly cured. The inhalations in these cases must consist of ammonia, vapour of tar, with the vapour of several volatile oils."

The formula used and recommended by Dr. Caldwell in the article referred to above is as follows:—

R. Ext. belladon. fld., gtt. v. to x,  
Potass. bromid., ℥j.;  
Ammon. bromid., ℥ij.;  
Aqua distil., ℥ij.

M. Ft. solutio.

Of this we use a tablespoonful at each application.

We—Dr. R. T. Maxwell and myself—have always used a solution of nitrate of silver, gr. xv. to the ounce, applied by the spray atomizer; we have found the treatment so satisfactory that we have had no occasion to make any change of formula. The first case that we treated with the spray atomizer was that of Harry S., aged six years (January 1871), a very severe case; the little fellow expectorated blood after every paroxysm. We tried the spray atomizer as an experiment, instead of making the application by means of the brush or probang, which Dr. Maxwell has relied on entirely for about ten years. The child improved after the second sitting, and on the fifth he was nearly well. A few days ago, as I was using a spray atomizer with two children of Mrs. M., she remarked that about six years ago, when four of the older children had the whooping-cough, Dr. Maxwell cured them entirely by brushing their throats four or five times. There is no doubt in my mind that local applications are all that is necessary for the treatment and cure of whooping cough. And there is very little doubt that there is a variety of substances that can be used for the purpose. The solution of nitrate of silver, however, will seldom fail to effect a cure.

#### A Contribution on the Structure and Development of the Psammoma, by Professor Julius Arnold, M.D., Heidelberg.

In this paper three cases of the psammoma, or sand tumour of the brain, are very fully detailed. These tumours are generally very soft, but one of those described was of firmer consistency than usual, and therefore more fitted for examination by sections. It was first placed in dilute solution of chromic acid, by which the lime salts were extracted, and afterwards in alcohol, in order to prepare it for making sections. From his examination, especially of this tumour, the author concludes that the spheres and rods impregnated with lime, which are commonly found in these growths, often have their seat and take their origin in the blood-vessels. They may arise from these in various ways—first, by calcification of the contents of the vessels as of a fibrinous coagulum; second, by calcification of the walls of the vessels; third, by a combination of these two methods; and lastly, by a local growth of the adventitia taking place, and calcification occurring in it. But this is not the only origin of those inorganic gritty deposits which give their name to this class of tumour. It was found that the bundles and fibres of connective tissue sometimes became calcified, also groups of cells, and spheres formed of cells, and finally, that concretions having no organic origin may be deposited. Looking to the facts brought out in his examination of these tumours, the author considers that in their earlier stages they are probably very soft, connective-tissues tumours,

perhaps partly myxomatous, and very rich in blood-vessels. At a certain period the tissues present a very great tendency to calcareous degeneration, and this may attack all the constituents of the tumour equally. But sometimes one particular tissue may be more specially attacked, or the disease may be more advanced in it, so that, for instance, the blood-vessels may present a higher degree of calcification than the other constituents of the tumour.—Dr. Joseph Coats in *Glasgow Medical, from Virchow's Archiv.*

## Inventions.

EVERYONE knows that the pressure of the old bunionspring fell upon the joint through the lever being fixed to a ring that encircled the joint. The consequence of this arrangement frequently was inflammation and supuration, and the unfortunate patients lost all faith in the method of cure, by separating the toes. Still, that principle was the right one. We only wanted a mode of applying it without aggravating the suffering. For this purpose, Mr. Miller, of Leicester square, has devised a bunionspring, which acts by means of two pads between the toes, and two springs on the instep. All pressure is, therefore, between the toes where it can do no harm. In fact, Mr. Miller's bunionspring pushes the great toe out, instead of pulling it out by a lever whose fulcrum was on the tender joint. The following engraving explains the

mode of applying it. It has the additional merit of being one third of the price of the old-fashioned spring.

## NOTICES TO CORRESPONDENTS.

THE Editor of the "Irish Medical Directory" earnestly requests that all those persons who have received the Circular of the "Directory" for correction of the entry therein, will have the kindness to return it to him without avoidable delay. The Editor also appeals to the profession to enable him to issue the "Directory" free from the imperfections which other similar publications contain. Wherever the residence of a medical practitioner cannot be ascertained, the name will be omitted altogether, and it is needless to say that, unless the necessary information is afforded him by medical men themselves his publication must be spoiled by many inaccuracies. Lastly, the Editor appeals to the profession in Ireland for a hearty financial support for his venture. It will not be denied that a reliable Directory of the profession in Ireland is much wanted, that there is much worth collecting for daily reference which no publication intended for the three Kingdoms could fill its

pages with, and the Editor believes and hopes it will be worth the while of the profession in Ireland to go a little out of its way to sustain a yearly publication of the sort. The expenses, especially of the first year, will be very heavy. A five shilling contribution for a good book is not a great acknowledgment on the part of each well-to-do medical man, for the great labour involved in the publication. The Editor hopes his venture may meet with such a reception as to encourage him to continue the publication of the "Roll of Irish Medical Men," which he now issues for the first time.

MR. STREAD, Manchester.—In our next.  
THE CHICAGO FIRE.—The report which has gained currency, that Dr. Frear, a distinguished American physician, had perished in the flames, happily turns out to be incorrect. The latest telegram states, "Dr. Frear was not suffocated, as is supposed."

## VACANCIES.

North Devon Infirmary. House-Surgeon. Salary £100, with board.  
Nottingham General Hospital. Resident House-Surgeon. Salary £150, with board. Assistant House-Surgeon. Salary £60, with board.  
Great Ouseburn Union. Medical Officer. Salary £50 with extra fees.  
Westminster Hospital. House-Surgeon. Board and residence, without Salary.  
Great Northern Hospital, London. House-Surgeon. (See advt.)  
London Fever Hospital. Physician. Honorary.  
Central London Ophthalmic Hospital. Assistant-Surgeon.  
Preston Infirmary. Two House-Surgeons. Senior, at a Salary of £120. Junior, at £80. Each with board and residence.  
Fulham Union, Middlesex. Medical Officer. Salary £56, with fees extra.  
Royal Hospital for Diseases of the Chest. Surgeon. (See advt.)  
St. George's Dispensary, Hanover square, W. Physician Accoucheur. (See advt.)  
Metropolitan Dispensary. Surgeon. Election, 7th ult. (See advt.)

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.  
St. Bartholomew's Hospital Reports, Vol. VII. London: Longmans.  
Neuralgia and its Counterparts. By F. E. Anstie, M.D. London: Macmillans.

Intermittent Malaise. By Dr. Henry Adams. London: Lewis.  
Report on Spiritualism. London: Longmans, Green, and Co.  
Revelations of Quacks and Quackery. Third Edition, enlarged. By F. B. Courtenay, M.R.C.S. London: Baillière, Tindall, and Cox.  
Fecundity, Fertility and Sterility, and Allied Topics, 2nd Edition. By J. Mathews Duncan, A.M., M.D. Edinburgh: A. & C. Black.

## MEETINGS OF THE LONDON SOCIETIES.

FRIDAY, Oct. 27th.—QUEKETT MICROSCOPICAL CLUB.—8 P.M. Mr. T. Charters White, "On the Microscopical Structure of the so-called 'Nerve' of a Tooth."  
CLINICAL SOCIETY.—8½ P.M. Dr. C. T. Williams: "Cases Illustrating the Contraction of Cavities in Phthisis."—Dr. John Murray, "On a Case of Paracensis Thoracis."—And other papers.  
Monday, Oct. 23rd.—MEDICAL SOCIETY at 8 P.M. Ordinary.

## APPOINTMENTS.

ARMSTRONG, J., M.B., L.R.C.S. Ed., Hon. Assistant Medical Officer to the Liverpool Infirmary for Children.  
CARTER, S. H., A.B., M.B., Assistant Resident Medical Superintendent of the Bristol Lunatic Asylum, Stapleton.  
FAGGE, Dr. C. Hilton, Physician to the London and Westminster Bank, in the place of the late Mr. Solly.

## Births.

CLARKE.—On October 18th, at Duke street, South Molton, Devon, the wife of Francis Edward Clarke, B.A., M.B., Oughterard, Galway, of a son.

## Marriages.

GAY—THIMBLEBY.—On the 12th inst., at the Parish Church, Spilsby, by the Rev. W. Smith, John Henry Gay, M.R.C.S., Spilsby, to Alice, elder daughter of Dr. Thimbleby, of Spilsby.  
POWIS—STEWART.—On the 12th inst., at St. Giles's, Camberwell, H. S. Powis, M.D., of Maidenhead, to Mary, second daughter of Ramsay Stewart, Esq., of Edinburgh.  
TAYLOR—HINCHELFF.—On the 19th inst., at St. Mark's Church, St. John's wood, Gabriel, third son of John Taylor, M.D., of Girvan, to Lucy, daughter of A. Hincheliff, Esq., of Sydney, N. S. W.  
WALSH—SCHOLFIELD.—On the 11th inst., at St. Bartholomew's, Whitworth, Rochdale, Alex. Walsh, M.D., of Glasgow, to Jane, fourth daughter of the late Jas. Scholfield, Esq., of Tongend, Whitworth.  
WRIGHT—TOLLER.—On the 12th inst., at Kettering, J. Brampton Wright, M.D., of Wellinborough, to Caroline Addison, second daughter of W. Toller, Esq., of Rockingham road, Kettering.

## Deaths.

CAMERON.—On the 30th ult., Dr. Evan Cameron, of New Abbey, late of Bradford, Yorkshire, aged 72.  
CHRISTIAN.—On the 17th inst., James S. Christian, M.D., of Thurloe place, South Kensington.  
FAITHORN.—On the 12th inst., George Faithorn, M.R.C.S.E., of Chesham, Bucks, aged 61.  
FAWCUS.—On the 11th inst., at North Shields, J. Fawcus, M.D., aged 38.  
SMITH.—On the 10th inst., at Darvel, R. M. H. Smith, M.D., aged 27.  
THOMSON.—On the 10th inst., at Perth, Frazer Thompson, M.D.

## COCKING'S PATENT POROPLASTIC SHEETS FOR SPLINTS.

"Consists of a felt substance, is plastic when heated, and rigid when cold, rapidly and easily cut to any shape, and manipulated. We have no hesitation in recommending it as the best and most convenient Splint. The country practitioner will find it a special boon. Mr. Cocking (of Penzance), deserves the thanks of many, inasmuch as he supplies it to hospitals almost at cost price."—*Medical Press*, Sept. 27, 1871.

"By attending to the very simple directions for use, the most perfect splint yet known, may be made. We earnestly recommend it to army surgeons, believing that for field hospital purposes, it will supersede all others."—*British Medical Journal*, Sept. 23, 1871.

"Mr. Cocking (of Penzance), has laid the profession under much obligation by his sheets for splints, which have succeeded admirably, and will prove highly useful to the surgeon, particularly in the country."—*Lancet*, Sept. 16, 1871.

"To practitioners in the country and colonies, 'Cocking's Splint' will be of the utmost service. It has been used with success by our leading surgeons, and has found to answer all that was required or expected."—*Medical Times*, Oct. 7, 1871.

"To Country and Colonial Practitioners, invaluable."—Extract from the report of the London Hospital, by Jonathan Hutchinson, Esq., Senior Surgeon, Sep. 29, 1871.

"A great boon to medical men in the country. In town and hospital practice invaluable. Its porosity is one of its greatest advantages."—Extract from report of St. Thomas's Hospital, by John Croft, Esq., Oct. 6, 1871.

"Without doubt the material will come into very extensive use, when its valuable qualities shall have become more generally known."—Extract from report of Guy's Hospital, by A. E. Durham, Esq., Oct. 7, 1871.

The average cost of a medium size perfect Splint being from 6d. to 2s.

## WHOLESALE AGENTS:

Maw, Son, & Thompson, 13 & 14 Aldersgate street, London, E.C.

Weiss and Son, 62 Strand.

Coxeter Sons, 23 Grafton street, W.C.

and at the depot of this Invention, Benj. Wilson, Walbrook House, E.C.

**METROPOLITAN DISPENSARY AND CHARITABLE FUND, 9 FORE STREET, CRIPPLEGATE.**—The Office of Surgeon to this Charity is now vacant by the resignation of Sidney Chater, Esq. Candidates must be Fellows or Members of the Royal College of Surgeons of England, not practising Pharmacy. Testimonials will be received at the Dispensary until 4 o'clock on Tuesday evening, the 7th November, when Candidates must attend the Committee with their diplomas, and the Committee will fix the day of Election. All further particulars relating to the Institution, and the duties of the Office, may be obtained upon application to Dr. Southwood, the Resident Medical Officer, or to the Secretary.

By Order of the Committee,

FREDERICK STILES, Secretary.

6 Fore street, Oct. 1871.

## COKESTOWN HOUSE, INSTITUTED FOR

**THE MEDICAL TREATMENT OF THE INSANE OF BOTH SEXES.**

This highly respectable Mansion in no respect resembles, either internally or externally, what is usually known as an Asylum.

The Demesne, Conservatories, Graperies, and Grounds are unusually extensive, and in good condition.

There are Billiard Tables for both sexes, with indoor and outdoor amusements, including Vehicles.

Cokestown House is within three miles of Carrick-on-Suir Station, with a like distance from Fiddown, both on the Waterford and Limerick Lines, and in connection with the G. S. & W. and Kilkenny Lines.

For terms, and Form of Admission, apply to the Resident Physician.

JOHN PEPPARD, M.D., &c.

Cokestown House, Pittown, co. Kilkenny.

**THE ROYAL HOSPITAL FOR DISEASES of the CHEST, City road.**—Founded A.D. 1814.

Under the direct patronage of Her Majesty the QUEEN.

Notice is hereby given that the Council will meet in the Board Room of the Hospital, on Tuesday, the 7th day of November next, at half-past 4 o'clock p.m., to receive and examine APPLICATIONS from candidates for the OFFICE of (OPERATING) SURGEON to the Hospital, vice Mr. Francis Mason, F.R.C.S., resigned. Candidates for this office must be Fellows or Members of the Royal College of Surgeons of England not practising midwifery or pharmacy.

Any further information may be obtained on application to the Secretary or Resident Medical Officer, personally or by letter.

Letters on application, addressed to the Council, with testimonials, to be sent to the Hospital, directed to the undersigned, before the time above-mentioned.

The election will be held at a Special General Court of Governors on Tuesday, November 21, the names of candidates approved by the Council being previously announced.

CHARLES L. KEMP, Secretary to the Council.

City road, Oct. 10, 1871.

**HOUSE - SURGEON WANTED,** at the GREAT NORTHERN HOSPITAL, Caledonian road, N. Candidates (M.B.C.S.) are invited to send their application and copies of testimonials to the Secretary, 46 Great Cornam street, W.C., on or before 30th October.

By order,

GEORGE REID, Secretary.

Established 1848.

## PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY LL.D. M.R.C.S., F.L.S.,

&c., (KISO's COLL.), and Author of VIA MEDICA,

Has always upon his books a large number of desirable investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays, from 11 till 2.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for negotiation (in addition to those advertised in Dr. Langley's List, (which is sent post free on application).

Y 293. Excellent opportunity for commencing PRACTICE. Open Surgery in an Eastern Suburb, returning about £5 a week in cash; has been neglected, but can be worked up to £500 a year. Expenses of living and rent very low; house contains six rooms, with stabling, &c.; clubs bring in £14 a year, premium for goodwill, stock, fixtures, &c., £150, half of which may be left on security.

Y 319. GOOD CLASS WEST-END PRACTICE for transfer, with twelve months' partnership introduction. Average receipts, including the present year, £800, or based on three previous years, about £700. The practice is conducted with very little trouble or expense, having been carefully selected and confined to a narrow area. Very little midwifery, and no night work. No assistant required; fees good. The house is in a commanding situation, held on beneficial lease, at £75 a year.

Y 320. In a pleasant and improving TOWN, a very OLD-ESTABLISHED PRACTICE, held by vendor for the last seven years. Average receipts about £760 a year, including easily worked Appointments producing £200 a year. No union. One Horse and carriage sufficient; the patients are chiefly of the upper middle-class. An efficient introduction can be guaranteed; part of the premium may be left on security.

Y 321. NUCLEUS in the HOME COUNTIES. The Practice is unopposed, and at present yields about £300 a year; population of district, 3,200. Appointments yield £164 a year. Pleasant cottage with every convenience. Rent £300. The whole within easy access of London, premium £200.

Y 317. MIDLAND.—Receipts upwards of £800 a year, including valuable Appointments yielding £220 a year, No resident opponent within two miles. Patients good middle-class. Efficient introduction.

Y 313. Partnerships in a first-class Country PRACTICE, in a WESTERN COUNTY. The income was formerly £900 a year, but has declined in consequence of the advancing age of the incumbent; who, however, retains the best part of the connection, returning fully £600 a year. The Practice is capable of almost unlimited increase, as the district is populous, and there is no opposition within four miles. Two horses and one carriage are used. Appointments yield £110. A suitable gentleman would be admitted upon easy terms, but must be able to command £500.

Y 312. High-class Non-dispensing PRACTICE with Partnership introduction. The average receipts have been about £1,000 a year, but have increased largely during last year. The patients include the aristocracy of the district. Midwifery fee, £5 5s. to £10 10s. Nearly the whole Practice lies within a mile radius. Visits, 5s. and 7s. 6d. The incumbent holds two government appointments, which yield about £100 a year. The residence is one of the best in the locality, in a charming situation, commanding a view of the sea and parts of the South Coast; being the Vendor's freehold, it can be purchased, or rented, or a smaller house adjoining could be occupied by the partner during the introduction. The successor must be well-qualified and accustomed to good society.

## Original Communications.

### ACCOUNT OF A CASE OF OBSTRUCTION OF THE SMALL INTESTINE.

By JOHN C. THOROWGOOD, M.D.,

Assistant-Physician to the Hospital for Diseases of the Chest, Victoria Park.

Mr. G., æt. about fifty years, had generally enjoyed tolerable health, and had only been in the doctor's hands for occasional attacks of dyspepsia, which yielded to treatment. He could not recollect ever having had any inflammatory attack in the bowels.

On Sunday, October 8th, he had a good deal of abdominal pain, believed by him to be due to indigestible food, and this pain continued with varying degree of severity during the week. The bowels acted somewhat imperfectly, till Friday, when there was great increase of pain, and neither by purgatives nor by enemata could any further action of the bowels be obtained.

I saw Mr. G. in consultation with Dr. Dixey, of Finchley, at ten o'clock on Sunday night, Oct. 15th. He was then found lying on his back with knees drawn up, a small thready pulse of 140<sup>2</sup>, short respiration, frequent vomiting of matter having a stercoraceous odour, and clammy sweat over his face.

The abdomen was uniformly enlarged, no special bulging anywhere, either in front or in flanks. Below and to right of umbilicus it was especially sore and tender, and from this spot the soreness extended all over the surface of the belly. The abdomen was moderately tympanitic, no movement of intestines could be seen, felt, or heard,

even on listening with stethoscope. Dr. Dixey had already carefully sought for any rupture, and had also examined the rectum. I repeated the same examination, and we were satisfied as to the absence of any rupture; the rectum I found empty, and with ease I introduced nearly the whole length of a No. 12 catheter.

Under these circumstances, coupled with the fact of the enemata having passed freely into the bowel, I suspected the seat of stricture to be near the ileo-colic valve. Opium having been already given in accordance with the best rules in these cases, we now tried belladonna, applying the ointment externally, and giving the extract in pills, though it was clear enough to both Dr. Dixey and myself that the poor man had not long to live.

He died next morning, and Dr. Dixey having obtained leave to open the abdomen, found the obstruction to be due to a band of lymph, not thicker than a piece of twine, which had its ends attached to the mesentery, and encircled the ileum just before it joined the cæcum. The small intestines above this point were enormously distended, and for ten inches above the stricture, were of a deep claret colour. There was a good deal of effusion into the peritoneal cavity.

The sudden way in which the more urgent symptoms in this case came on, seemed to coincide with the nature of the obstruction which must have rather suddenly caused complete occlusion of the bowel, presuming that the bowel slipped into the loop of mesentery.

Peritonitis rapidly supervened, and there were not observed any of those writhing and twisting movements of the large intestine seen and felt, when some obstruction exists low down in this bowel.

The free use of opium by mouth and by injection, as employed by Dr. Dixey was clearly the best treatment to employ under the circumstances of the case. The early employment of gastrotony might have succeeded in liberating the bowel; but it is with this operation, much as it is with tracheotomy in croup and paracentesis of the chest, one hesitates to resort to such severe and hazardous operative procedures early in a case, while there seems reasonable hope of milder means effecting the desired results.

HINTS ON METHOD.

BY W. H. PEARSE, M.D. EDIN.

THE emigrant ship, *Alumbagh*, left Plymouth for Melbourne in July, 1870, having on board 136 men, 190 women, 82 children between one and twelve years, and 4 infants under one year. The voyage lasted 90 days.

An epidemic of measles prevailed. In this instance, as in most other experiences of isolated communities on ship-board, phenomena presented themselves with much variation from what is commonly seen on shore; and as the varieties, or "exceptional instances" which are presented to our view in the course or history of phenomena, are those, more than the common rates, which have great suggestive import to our minds, I have thought that a short account of the voyage might be worthy of record and thought.

Twenty-four cases of measles occurred: the first seven days after sailing, the last after being at sea eighty days.

The weekly order was:—

| Wks.   | 1       | 2 | 3 | 4 | 5 | 6    | 7 | 8 | 9 | 10  | 11 | 12 | 13       |
|--------|---------|---|---|---|---|------|---|---|---|-----|----|----|----------|
| Cases. |         | 1 |   | 1 | 2 | 1    | 8 |   | 5 |     | 3  | 1  | 2        |
| Place. | 50° NL. |   |   |   |   | Line |   |   |   | Cpe |    |    | 40° S.L. |

I append a statement of the temperatures of all the cases except the two first; these two were not taken; their symptoms were of the mildest type. Besides the morning and evening temperature, I have noted the days of ailing "A," the days of eruption "S," the pulse, and in some instances the breathing.

| DAYS.   | 1                   | 2   | 3   | 4       | 5     | 6         | 7     | 8     | 9                                   |  |

| M 4   | Pulse<br>M E        | A A | S S | 101.8 | 101   | 97.8  |      |      |   | Bronchitis.                   |
|       | Tmp.                |     |     | 102.2 | 101.7 |       |      |      |   |                               |

Here was an epidemic of eruptive febrile cases: from their occurrence in an isolated community, from the general resemblance of the symptoms in the different cases, their general history and duration, they must be viewed as allied cases; or, to use the common phraseology, as an epidemic of a so-called "specific disease."

Among the facts observable are the short duration of each case; the low range of "febrile" temperature, no case having reached 104°, and most not showing a temperature above 102°; a very rapid pulse coexistent with a low febrile temperature, and the very rapid breathing. Case nine, in which acute general bronchitis showed, gives on successive days.

|           |       |       |       |
|-----------|-------|-------|-------|
| Temp.     | 103.6 | 102.4 | 101.6 |
| Pulse     | 154   | 148   | 150   |
| Breathing | 66    | 72    | 90    |

The eruption was in most cases full, and like measles. I have not been able in observing many measles epidemics, to distinguish the lines which systematic writers and nosologists draw, as distinguishing measles, rubeola, and scarlet fever: the phenomena at the later periods of some such epidemics have assumed no other symptoms than sore throat, or bronchitis, or diarrhoea. In the absence, however, at present, of a sound basis for a wider generalisation, the epidemic of the ship *Alumbagh*, must be called measles.

The most prominent idea which evolves in the mind, in the observation of diseased phenomena, under the circumstances of the changed physical and other relations of

voyages at sea and in other climates, is the great danger of error of method which is involved in the giving distinctive names and definitions to phenomena, even to the degree of the frequent assertion of the dicta of "specific diseases." However important and unavoidable it may be to give distinctive names to groups of similar phenomena; yet it must not be forgotten that such assertions of the existence of "specific diseases," is a proof of the present very early stage of our knowledge; to rest the mind in the assertion of "specific diseases," to view such allied phenomena as typhus and typhoid fever, measles, scarlet fever, yellow fever, &c., as each the result of the action of "specifically distinct poisons," is to remain in medical philosophy without the reflected light which other knowledge might give; it is to borrow no light of method from those wider generalities, which E. J. F. Schlegel taught us in Languages, Grove on Forces, &c., and which, indeed, lights up the method of all knowledge, more than that of medical art.

We should feel ashamed, on this day, not to recognise the "great periods," "slow rates," the "value of phenomena," and the "value of difference," in the evolution of races, faiths, languages, philosophies,—we know by an almost *à priori* method, that the varied languages, animal and vegetable forms, forces (so-called), faiths, &c., are more allied than different—are parts of evolving series; we recognise now no "monsters;" diseased structures are now perceived to be but naturally contained deviations from more prevalent normal types, and yet in viewing any group of allied febrile or other symptoms, we rest in the method of asserting the dicta of "specific diseases," and "specific causes."

The so much viewing diseases as specifically distinct, and as the result of specific causes—"germs" is the fashion of the hour—has very much led to two grand errors of method; the one is, that now so prevalent by which we expect to get rid of fevers, cholera, &c., by what are known as hygienic measures, as directed against certain assumed miasmas, poisons, &c.; the other error, which, at any rate, goes along with the former, is our practice of treating symptoms; and, indeed, one may say, the appalling state of our therapeutics.

It is with a species of agony that one finds, in the East and West Indies, in America and Europe, the forms or gradations in the phenomena of human bodily deviation (diseases), looked on as "specific existences." It is strange that the same men whose ideas range in the most advanced light or method in all other sciences, remain in medical art in the dark method of the treatment of symptoms.

For many years past, seeing disease in many climates and countries, and aiming to keep the mind in a state apt to receive truth, I have felt that such deviations from normal rate, as are measles, scarlet fever, typhoid, remittent, typhus, cholera, yellow fever, ague, &c., are not only not "specifically distinct," but that they are part or degrees of one series. Their comparative differences are not greater than we all recognise in variations of animals, plants, languages, &c., now felt to be of one series. Such views have always appeared to me as truths, even on an *à priori* method.

If we, for a moment, remember the past history and present state of the medical treatments of cholera, fevers, and constitutional diseases, &c., we may well reconsider our method; and in the present hour our search after specific "causes," specific germs, &c., as producing cholera, yellow fever, &c., is but a most partial and narrow one.

We must rather view these deviations or diseases as natural, and contained and evolved rates of the human body, in its present state of composition and relation; it is the *capacity* for these changes of rate (diseases), which is the great fact. Our search for remedies must be the prophylactic one, of supplying the material body with a state of relation or composition, such that the deviation of rate into the, *e.g.*, febrile series, &c., cannot happen.

One recent and painful instance of bad medical philo-

sophy and method is, the proposal of the "eliminative" treatment in cholera. It is *à priori* obvious that to treat symptoms in cholera is worse than useless. Symptoms are ulterior events; the potential paralysis, the changed relation in composition within the body, the chill (or whatever it may be), is anterior to the symptoms; it is to remove the capacity for such first potential change which should be our aim. Cholera occurs in India, just as sore throat does here; the terrible difference in danger of the different cases, should have no weight to the philosophical student, to close his view to the wider analogies and oneness of phenomena which, to the vulgar, appear so different.

As indications of true prophylaxis, are the facts of natives of India remaining free from cholera when changed to the climate of the West Indies—also when, after the first few weeks of the voyage from Calcutta are passed—here some change has happened in his system coincident with changed climates. Such change may be infinitely slight, yet it is all potential; again we see instances where small quantities of material substance are added to the system, such as quinine, vaccine lymph, iodine, arsenic, the elements (forms) of mineral waters, &c., having the effect of removing the capacity for ague, small-pox, various skin and other constitutional diseases; again, that the negro or the acclimatized European, does not—cannot—take on the rate or state of yellow fever, is the result of some infinitesimal and co-ordinated state of composition of their bodies.

Our hope for further light and exacter knowledge is less by the vast accumulation of experiment and statistics, than by the perception of analysis and alliances.

Should material miasmas, cell germs, &c., be proved to be true parts in the *role* of fevers, cholera, &c., yet the greater fact will remain, that our hope of treatment and management will be that of sustaining the system's natural composition and relation; the rust in wheat; the fungi in certain skin affections and in cholera, &c., occur of necessity, when certain previous conditions having evolved in the grain or system, gives the capacity for their development.

That stage of intelligence which was for ever seeking "causes" (so called), still lingers too much in medical method, its fruit may be seen in the long but hopeless search after miasmas, poisons, germs, &c., but perhaps its worst fruit has been the method of treatment of symptoms.

Many most suggestive illustrations for the search of true remedies might be cited, *e.g.*, we see cancer as native to the robust in adult age. Tubercle as native to certain most evolved or feeble at earlier ages; one may say that both these diseases are the very nearest to normal, of changes which could happen, they are amongst the first deflections of the normal rate or composition, and one cannot doubt but that the supply of a small amount of some mineral element, some "form" now wanting, would be potential to retain the balance of normal cell-growth. The same method of hope for prophylaxis against the febrile series, extending from infancy to age, and against the series of the constitutional diseases of adult life, suggests itself. Neither chemical analysis or microscope can be expected to reach the form of what the changes really are, nor indeed is such knowledge necessary, but analogy and the interpretation by a right method of phenomena very open to us, may lead us to potential remedies.

The habits and instincts of East Indian races when not spoiled by Western civilisation, are sometimes most suggestive and far more valuable than the dicta of the newly evolved Western science, in its present stage. I have been obliged on different occasions to treat the chronic diarrhoea of India variously with lemons, baked grain (a kind of bean), onions, raw or fried, garlic, &c. The patients reduced by months of illness, leathed rice, arrowroot, milk, meat, &c. Rapid recovery often occurred. Children of two years, as well as adults, have a passion for such articles of food, and under their use recover. Similar patients will sometimes commence

to eat and recover, on getting black salt. On one occasion, at the end of a hot Australian summer, I found a large number of children down with the severe semi-chronic diarrhoea, common at the end of the hot season; they loathed milk, fresh meat, arrowroot, &c., but craved for salt meat, onions, vinegar, pickles, &c. I hold that these cravings are profound indications to us for our plan of treatment, and on the other hand, I believe children are largely sacrificed to the arrowroots and orthodox treatments of our civilisation. But beyond these, there are other most suggestive facts toward prophylaxis. I have known patients long ill of phthisis pulmonalis crave for various forms of shell-fish (lobster, &c), onions, other cases of phthisis regain almost strength when living in the smell of sea-weed. The smell of the sea-weed seemed a passion, and surely must indicate that in the sea and some of its parts or vegetation, &c., and close at hand, are the mineral elements or "form" which, added to the system's composition, would sustain the normal rate of cell-growth, and thus healthy lung tissue. The early forms of fish have a most persistent vitality of tissue; we do not look for the failure of cell-growth, and the increase of tubercle in the shark, or albatross, or eagle.

The perception of the alliances of phenomena, which to vulgar view appear specifically distinct, the ceasing, the bad habit of assertion, the submission of the mind in charity (Bacon), and recognition of the great periods and "slow rates" of the evolution of existences, are essential to give us a hope even of seeing and knowing truth. That which Coleridge called the "illuminating idea," is but little existent, in our present method of search after "causes" or in our method of treatment of symptoms, must be most painfully felt by every earnest student of medicine.

### THREE CASES OF NEURALGIA CURED BY THE USE OF THE CONSTANT GALVANIC CURRENT.

By JOSEPH STEAD, M.R.C.S.E., Manchester.

I. THE first occurred to a well-known merchant in Manchester. He was forty years old, and came to me on the 5th of June last, with intense frontal neuralgia, which had lasted a fortnight. It was most severe in the supra-orbital branches of the frontal nerve. Five minutes' gentle application of the Continuous current by means of small wet sponges attached to small conical conductors sufficed to cure him of his torment on the spot, and it never returned. "I wish," he said the next day to me, "I had known you a fortnight ago. I should have had a very different Whitweek to what I have had!"

II. THE second case I shall mention occurred in a young lady, a governess with a leading merchant's family in this neighbourhood. She had intense neuralgia of the left side of the face, which she attributed to the partial extraction of a tooth ten days before. I applied the current as in the last case, but with slender hopes of relieving her. One application, however, completely freed her from pain for a fortnight; and then she returned with it again, when a similar application effectually removed it, and there has been no return.

III. My third case occurred on the 4th of this present October, to a valued female servant of an old patient of mine. She was a girl of about twenty-four years of age, and had been suffering from facial neuralgia of both sides for three months. For two nights previously to coming to me, she had been compelled to get up from bed and come down stairs and spend the night awake, and in great agony. Five minutes' application cured one side of the face, and a second five minutes' application cured the other, and then, to my surprise, "tired Nature's sweet restorer" overwhelmed the poor girl, and she fell fast asleep in her chair at my house. And here, again, there has been not the slightest attempt at return of pain.

These three cases have been selected from the records of my practice in the use of electricities during the last two

years in the cure of disease to illustrate the truly marvellous power which the constant galvanic current has over pain. The battery used in all three was Weiss's, sometimes known as Foveaux's. I used about eight cells of this splendid battery, with very small sponges (about as large as would fill the end of a thimble) soaked in warm water, and fixed, as I have just said, to those small conical electrodes which are used for the localisation of the current in paralysis of the interossei and lumbricales muscles. I applied them to the part where the pain was, keeping them about one inch apart from each other. I moved them about, but did not remove them, or either of them, from the skin for about two minutes. I then rested for one minute, and applied them again for two minutes more. If the pain had not been removed I should have gone on for another five minutes. But as soon as the pain ceases in a case of neuralgia I make it a rule immediately to discontinue the application. In each of these cases I directed the patient to come daily for a repetition of the operation. But, happily, there was no need for this.

### DIARRHOEA AND CHOLERA:

#### THEIR SUCCESSFUL TREATMENT BY MEANS OF THE SPINAL ICE-BAG.

##### A SUMMARY RECORD OF CASES AND RESULTS.

By JOHN CHAPMAN, M.D., M.R.C.P.,

Physician to the Farringdon Dispensary.

(Continued from page 274.)

In a paper entitled, "The Treatment of Epilepsy: Principles and Practice," read by me at a meeting of the London Medical Society, March 18th, 1867, I gave evidence of the marvellous power of the Spinal Ice-bag in stopping convulsions and especially convulsions in children. During the debate on that paper, two of the members stated that their own experience confirmed my statement. Dr. Routh, "who had tested the principle [of treatment] in several cases of infantile convulsions," said, "In one case the child had twelve convulsions in one day, and, of course, under ordinary circumstances, could not be expected to recover: the convulsions ceased as soon as the Spine-bag was applied, have never recurred, and the child is now quite well." Dr. Rogers said—"One of his children had convulsions during thirty-six hours: ice applied to the spine completely stopped the fits. And quite recently, in two cases under his care, of whooping-cough followed by convulsions, the convulsions ceased to recur after the Spinal Ice-bag was applied."\* Of the cases of diarrhoea given above, there are only two—viz., Cases VII. and XVII., in which convulsions occurred, but in both these cases they were quickly and permanently arrested by the Spinal Ice-bag. Moreover, "the spasmodic pains" in Case IV., the tonic spasms, convulsive twitches, and abdominal cramps in Case VI., the "convulsive starts" in Case XXI., which had lasted twelve months, the "violent jerks or starts" in Case XXIII., the pain (probably due to cramps) in Case XXV., and the cramps in Cases XXVI. and XXIX., were rapidly and completely stopped by the ice.

The vomiting, which was a distinctive feature in Cases VI., XVIII., XXII., XXVI., XXVIII., and XXIX., subsided scarcely less swiftly than the cramps just mentioned.

The rapid restoration of heat throughout the body by means of the Spinal Ice-bag, in those cases of summer diarrhoea in which a notable fall of bodily temperature shows their affinity with cases of cholera, will, I presume, be held to be a decisive proof of the power of the remedy to effect a beneficial and thoroughly constitutional change of the kind

\* See summary of the paper and of the debate published in the MEDICAL PRESS AND CIRCULAR of April 3, 1867.

most urgently needed in these cases, and one which no known drugs can be relied on to achieve. That the Spinal Ice-bag can do this is strikingly attested by the experience reported in several of the foregoing cases. In Case I. the patient, who but a short time before complained of being cold, and whose upper extremities were covered with cold sweat, reported "a glow of heat" all over her. In Case III. the patient "felt the effect of the ice very strikingly during the first application, especially in making the lower extremities along their whole course 'quite hot.'" In Case IV., at 9 a.m., the skin of the child was of "a light purple hue," its face and arms were "remarkably cool," and its legs and feet were "cold": at 3 p.m. of the same day, after three bags of ice had been applied, "he was generally warmer, and much more lively." In Case VI. the whole body was cold, and the head was particularly cold, yet during the first morning of treatment the circulation and normal amount of animal heat was fully re-established throughout the body. In Case X. the patient said to his wife—"The ice makes me warm." In Case XIII. the patient, who "became very cold each night during the attack," said he "became very warm after the application of the ice," and that he had not been cold at all during the two subsequent nights. In Case XIV. the patient, who, before using the Spinal Ice-bag broke out in cold sweat, which was followed by shivering, had neither "the cold sweat," nor the "cold feeling" after the treatment began. In Case XX. the patient became "notably warmer" during treatment. In Case XXII. the patient "became quite warm while she had the ice on the first time." In Case XXV., "while the ice was on the child it became quite warm." In the case of a "summer cholera," No. XXVI., the Spinal Ice-bag was first applied July 31st, and the next day the medical attendant found the "skin warm." In Case XXVIII. the patient reported "a warm glow over the limbs" within an hour after the ice was first applied.

*The sleep-inducing power of the Spinal Ice-bag* is also signally demonstrated in many of the above cases. In Case I. the diarrhoea recurred at 8 p.m. At 9.30 p.m., having applied the bag to the spine by lying upon it, she fell asleep, and, excepting a few minutes, slept continuously till 6 o'clock the next morning. In Case IV. the child fell asleep "in two or three minutes" after the ice was applied, and slept a full hour; and in this case the like fact was observed on almost every occasion when the ice was re-applied. In Case VI. the patient became very sleepy within five minutes after the ice was applied, and within half an hour she was in a sound refreshing sleep as she lay upon it. In Case VIII. the child's mother was greatly astonished by the fact she attested that *on every occasion* when the Spinal Ice-bag was applied the child slept on it. In Case IX. the child "was well contented with the ice, and each time it was applied slept on it." In Case X. the man "dropped asleep at once, slept during the whole time the ice was applied, and a long time afterwards." In Case XVII. it is reported that "the child sleeps much." In Case XVIII., "every time the ice was applied, the child went to sleep upon it." In Case XXI. the mother of the child says—"He generally sleeps on the Spinal Ice-bag each evening." In Case XXIV. the patient, who had been awake all night with diarrhoea, fell asleep in a few minutes after he was placed on the ice, and slept five hours. In Case XXV., within fifteen minutes after the Spinal Ice-bag was applied, says Dr. Williams, "the child was asleep, whereas it was crying bitterly before the application;" and again he says—"July 29 h, 10 a.m., after the ice was applied last night, the child fell into a comfortable sleep, which continued till 7 o'clock this morning."

*The rapid renewal of strength by the Spinal Ice-bag* is a fact noted in some of the preceding reports, and very often observable in cases of diarrhoea. This result of the treatment in question is scarcely less remarkable than the others just noticed. In Case IV., the child, which on July 28th was utterly prostrate, incapable of standing, in fact

partially collapsed, was running about the room and amusing himself, July 29th. In Case VI. the lady, who at 7 A.M. reeled and needed support when she attempted to stand or walk, "found, when she got up the first time after lying on the ice, that not only had the suffocative oppression and sense of faintness ceased, but that she had suddenly recovered her strength, so that she could again walk with her usual elastic step."

*The application of the Spinal Ice-bag is generally felt to be peculiarly comfortable, and in many cases positively pleasant.* In Case IV. the child's mother says, "He seemed to like the Ice-bag; he holds his head down to let the bag be put on directly I tell him the bag is coming, so I think it must be a comfort to him." In Case IX. the child's mother says, "She (the child) is well contented with the Ice-bag." In Case XXI., the child, who usually slept on the Spinal Ice-bag each evening, "would not go to sleep till he had had it; he insisted on having it." And Dr. Moorhead, relating his own experience, Case XXVII., says, "The Ice-bag proved most grateful." The Director of the Hydropathic Establishment at Melrose, who reported Case XXVIII., writes—"One thing has much struck me, viz.—the liking that sensitive chilly patients have for the cold bag to the spine, although frightened to think of it before they make trial." Dr. Druitt on one occasion saw some of my patients with me in order to inform himself of the results of my treatment of paralysis and epilepsy. After confessing that he was agreeably surprised by those results, and stating that "there was no mistaking the testimony of the patients that those results have been most beneficial," he adds, "I learned from all the patients that the treatment had made them more comfortable; I mean as regards their general feelings of health and animal sensations, without reference to the relief of particular symptoms." In several cases of sea-sickness—a malady having, as I affirm, an essential affinity with diarrhoea and cholera—the patients have reported their sensations induced by the Spinal Ice-bag to have been peculiarly agreeable. In fact, a remedy which steadily subdues and finally abolishes every symptom constituting or associated with the malady against which it is directed, can scarcely fail to operate pleasantly.

*The mode of action of the Spinal Ice-bag in producing the several special effects just reviewed* claims a moment's reflection, for in my opinion due consideration of it may throw "a flood of light" on the nature of not only diarrhoea, but of cholera also. The action of prolonged cold on living organisms is that of a sedative on the part to which it is applied; and the most manifest and characteristic result of the sedative influence of ice is diminution of the amount of blood and retardation of its movement *in the part which is immediately acted on*. The Spinal Ice-bag is applied over the spinal cord and collateral ganglia of the sympathetic nerve; and, as shown above, when thus applied it stops convulsions, it stops cramps, and the pains associated with them; it re-establishes the peripheral circulation, and makes warm the patients who were previously cold; it renews their strength with remarkable rapidity—sometimes with astonishing suddenness; it stops the vomiting and purging; it soothes the excited, and gives the restless sleep; and, withal, it substitutes for that deadly feeling of sinking and utter prostration peculiarly characteristic of severe diarrhoea, as well as of sea-sickness and cholera, a sensation of refreshment and of returning life and energy—a sensation which, under the circumstances, is the most agreeable of any which could be bestowed. Now if the application of the Spinal Ice-bag produces these several results, and produces them, as explained, by lessening the circulation in, and consequently the energy of the nervous centres acted upon, the conclusion that the immediate or proximate cause of summer diarrhoea and its frequent concomitants—vomiting, cramps, infantile convulsions, coldness, frequent restlessness and sleeplessness, and great prostration, physical and mental—consists in hyperæmia of those nervous centres, is, in my opinion, inevitable. But if with respect to summer diarrhoea and its frequent concomitants the doctrine which I have propounded be thus

verified and established by actual experience, this experience almost necessarily suggests the idea that inasmuch as several of the cases reported above which were especially severe, presented, though in a relatively mild form, all the leading characteristic symptoms of cholera, and inasmuch as all these symptoms were abolished by the Spinal Ice-bag, cholera itself, even of the severest type, is in respect to its nature and mode of origination, essentially identical with summer diarrhoea—is, in fact, but a great and terrific development of that disease, and is capable of being treated most successfully by practically recognising the fundamental principles which have dictated the treatment exemplified in the preceding cases.

## THE CASTOR OIL TREATMENT IN CHOLERA.

By R. HANSLIP SERS, M.R.C.S.

[THREE letters containing a plain refutation of the theory of treatment in cholera by castor oil and its advocacy by the Professor of Medicine at King's College Hospital, London, in 1854 and in 1871.]

I.—The subject that I beg to offer for consideration is the theory of treatment in cholera by castor oil; and I will endeavour to follow briefly and closely Dr. Johnson's representative opinions as expressed in certain letters, one of which is headed, "The Treatment of Cholera," published in the *Medical Times and Gazette* (Nos. 219, 221, and 224, in the year 1854). Therein this distinguished physician makes a dead set against opium, indeed, practically excludes it as an internal medicine from the "Pharmacopœia." Who could undertake to affirm of the sick that the blood was free from deleterious matter? Not even a neuro-humoral pathologist enlightened by what has been oddly termed "physiological pathology." Several years ago a practitioner roughly said of cholera, "If you stop the purging the vomiting will increase; if you stop the vomiting the purging will increase; and if you stop both the patient will burst out into a sweat for it will out." Opium, among numerous virtues, is a sudorific. It is stated to have "the peculiar property of arresting all the other secretions save that of the skin," a dogma which doubtless admits of amendments. Fortunately, we are able to modify the action of this drug with suitable adjuncts—thus, aperients, alteratives, antiphlogistics, &c.

Without pretence to the dignity of a therapeutical teacher, I should suggest that opium, duly administered, may produce the following effects :—

Characteristics of epidemic diarrhoea, tending to Asiatic cholera :—

Opium—a nerve tonic.

1. Depression of nervous energy.

—Gives tone to the heart and vessels, corrects irregular action, raises the pulse and temperature, and improves respiration.

2. Disordered circulatory system with extremely low temperature and impeded respiration.

—Stays the copious dejections, hence aids in restoring the blood to a due consistency.

3. Loss of normal fluidity of blood.

—Markedly relieves muscular cramps and spasms, alleviates pain, and subdues irritability.

4. Spasms and pain.

That the theory of treatment in cholera by castor oil (the greatest of all purges—Dr. G. Johnson), is objectionable can, to my mind, be enunciated from the subjoined premises :—

1. It is antagonistic to Physiology—contrary to her ordinary markings—the work curative is thrown upon the already overtaxed alimentary canal. Instead of endeavouring to restore the blood to a healthy condition by regulated action through organs designed to relieve these parts, to wit, the kidneys and the skin, &c., sickness is added to sickness and vomiting to vomiting. Also the natural function of the stomach and bowels is reversed; in fact, rendered abnormal. Surely this cannot be designated favouring the *vis medicatrix naturee*.

2. It is contradicted by the pathology of the disease. There is sometimes severe gastro-intestinal irritation. Although differences may be noticed elsewhere in cholera through the influence of climate or prior conditions of health, the effect upon the intestines themselves are pretty uniformly stated to be these—mucous membrane swollen and more or less congested in patches, general congestion, sub-mucous tissue, cedematous, and the glands of the intestine large and prominent. After all castor oil is essentially non-eliminative; gradual capillary percolation is what is required, not a mere rush of fluids. The blood is well-known to be stagnant, dark in colour, and of a pitchy consistency. A further pumping of fluid from the intestines aggravates the evil, thereby the tributaries are rendered increasingly stagnant, and how can waste matter be excreted from the system. Moreover, if the principle of treatment be correct a hydragogue cathartic is indicated.

3. It is opposed to the teachings of medicine. The castor oil theorists apparently ignore varieties of diarrhoea (autumn, spring, bilious, mucous, sympathetic, &c.); take no note of state of tongue, pulse, power of system, and former habits. All these plain indicators of treatment are sacrificed to the eliminative idea. Again, it is the undue stress laid on a special organ, or part, that usually gives to disease its *locale*.

II.—Venesection would prove a cardinal curative in morbid states of the blood, could we ensure the expulsion of poisonous products alone, minus the nutritive elements necessary alike to the patient's stamina, to an uninterrupted convalescence, and in several cases to life itself. Excessive watery secretion from the bowels is the reverse of elimination. The removal of accumulated feces or irritative matter is quite another affair. In diarrhoea we have to discover the origin of the disease in the liver, or spleen, or pancreas, or stomach, or nerves, or blood, or skin, or in the mucous membrane of the bowel, and to act accordingly. Hence judgment is required in treatment. Indiscriminate purgation frequently renders the abdominal viscera tender, and liable to inflammation, &c., during life. When the intestine has extra work to perform, the "repressives" hold with increased rest, not action, to enable it to retain its functions unimpaired. In the management of diarrhoea the purging has sometimes been stayed for two or three days, notwithstanding which the patient has failed to regain health and appetite. There then occurs a natural accession of moderate purging (the crisis), leading to a rapid cure and consequent return of appetite, and toleration of tonic. These two or three days repose have restored tone to the parts, and afforded the bowels power to effect the cure. This is true elimination, because the physiological law of rest has been obeyed. According to their own showing the "eliminatives" are not consistent with their creed, thus their plan is affirmed to be more effectual to stay the diarrhoea, and to do so in a speedier manner. Our system is to give opium about the commencement, their's at the termination. Our mode is to gradually withdraw foul secretions, and thus prevent unduly persistent action of the affected part. Their's is quite the contrary. There is a kind of diarrhoea which may be genuinely called a

natural eliminative process. I have such a case under my charge at the present time, and even in this case I am obliged, unwillingly, it is true, to give astringents. I refer to serous or watery diarrhœa occurring spontaneously in a case of ascites, with enlarged liver.

At the onset of sickness and purgation, the administration of an efficient emetic often proves beneficial, albeit when excessive they should be restrained. In urgent cases of vomiting a free action of the bowels will afford great relief. In dysenteric diarrhœa where the secretions are in themselves a source of direct irritation, castor-oil is pre-eminently useful, but it needs to be backed by a host of scientific accessories, medical and hygienic. I am led to these every-day observations by our physician's remark relative to the superintendence of epidemic diarrhœa. "It is a matter of comparative indifference whether the patient is dosed with sulphuric acid, or with carbonate of soda, except that the sulphuric acid in large doses must irritate the mucous membrane, and then act as an aperient."

Castor oil, notwithstanding its disgusting smell and flavour, is a popular remedy; however, patients add opium or brandy, perhaps the two, and habitually conceal home remedies from the attendant. Objections have been urged against this oil on account of its bulk and nauseousness, to these I would join its uncertain action and the subsequent anorexia produced thereby. Dr. Johnson calls it "the quickest of all purges," by which one understands the mild aperients. I question if this oil does act more promptly than saline medicines, when the latter are given so as to ensure their speedy effects, e.g., Epsom salts with small doses of quinine, taken early in the morning on an empty stomach, or an ordinary seidlitz powder, or certain of the natural mineral waters. Castor oil would have more signally failed. I cannot help thinking, were it not that after the first few doses, if retained at all, its resultant is constipation. ["In some cases we have considerable difficulty in obtaining the purgative action of the oil."—Dr. G. J.]

Under peculiar condition of the system purgatives become astringents, and astringents purgatives. It is these secondary effects of remedies that frequently bring discredit in the popular estimation on the faculty.

III.—I would fain add a few words about vomiting. The recumbent position of the patient gives it a peculiar danger—viz., suffocation. Further, there is generally no time to ascertain necessary particulars regarding the constitution. Retching may be emphatically forbidden. Perhaps actual hernia exists or an imminent tendency thereto. Atheromatous degeneration or aneurism may be present. The following case should serve as a caution:—"A child died in the Cholera Hospital, Bethnal Green; the intestines were intercepted in thirteen different places, the whole of the feces having been voided. There was a shrivelled corrugated appearance of the canal at these places and throughout different portions of its length."

One of the motives offered by the Professor for giving an emetic when patients are first brought into hospital is this, "to cast out such narcotic drugs as may have been previously given." I would in this place respectfully assume that the opiates must have altogether passed out of the stomach far beyond recall by any such means as this. In the Dreadnought Hospital ship only seven recovered out of nineteen treated by castor oil. Our authority accounts for this dire mortality by these assumptions, viz.:

"1. The average quantity of oil taken by these patients was much greater than we have ventured to give to ours."

(What more than a pint in forty-eight hours?—R.H.S.)

"2. Vomiting was of much less frequent occurrence than it has been in our cases."

(Attributed to an abundant supply of iced water instead of emetics.)

These are followed by two remarkable statements—"If every dose, or nearly every dose, of the oil is retained, it will usually be found as appears to have happened with the cases of the *Dreadnought*, either that there is little or

no purging, or that the purging is great and excessive." Again, "When, in consequence of all, or nearly all, the oil being retained and passing on into the intestines, the purgative effects threaten to become excessive, the medicine can safely be continued only in smaller doses or at longer intervals." It will be readily gathered from these observations that the physician should remain at the bedside of the patient during the administration of each dose of the oil.

Verily trustworthy trained nurses might, alarmed at the success of the eliminative process, stop short of the requisite curative dose. It cannot be too steadily borne in mind that the sensation of vomiting and purging is unfavourable only when it betokens a fatally depressed nervous system, a condition in which opium is not given, but at an earlier period it is beneficial. In old people and children the excellent results of arresting fluid alvine evacuations are marvellous. A diarrhœa that abates fever, &c., cleanses the tongue, can be regulated by simple care in diet. The pulse guides in these cases whether or not to pursue the ["hazardous and unreasonable practice"—Dr. G. J.] of giving astringents and brandy. Dr. Johnson writes—"In one case the addition of two drachms of oil of turpentine to one dose of castor oil appeared to act as a wholesome stimulant during the stage of icy coldness." But this was in September, 1854.

When we have arrived at an universal registration of disease, we shall then know how many thousand cases annually of looseness of the bowels stayed at the right time, have been prevented from passing into cholera, English, or Asiatic.

## Foreign Medical Literature.

### DR. KLEINWACHTER'S CONTRIBUTIONS TO THE HISTORY OF SPONTANEOUS EVOLUTION.

Translated from the *Annales et Bulletin de la Société de Méd. de Gand*, for the *Boston Medical Journal*, by F. W. DRAPER, M.D.

It is generally conceded that presentations of the shoulder, left to themselves, terminate but rarely by the spontaneous efforts of Nature, and are invariably attended with great risk. The author has, until recently, coincided with this opinion, but after a service of several years in a large lying-in hospital, he adopts another view, and regards the spontaneous termination of labours in which the trunk presents as less rare than the majority of accoucheurs are inclined to admit.

The statistics of various authorities take a wide range, although they all serve to show that the cases under consideration are sufficiently exceptional at the best. Thus, Rieker found, out of 220,000 labours, ten cases of spontaneous version, or '004 per cent. Busch, in 6,180 labours, gives two spontaneous versions, or '03 per cent. Spaeth, in 12,525 labours, has fifteen spontaneous versions, or '03 per cent. Kuhn, in 17,375 labours, reports nine spontaneous versions, or '05 per cent. The author's results are higher; in 3,345 labours he has seen five cases of spontaneous version, or 0'116 per cent. He thinks the greater frequency of spontaneous termination in such cases under his observation is to be attributed in part to the practice of the school to which he is attached; to the rarity of surgical interference, the labours being left as far as may be to the efforts of nature. Thus, he has observed cases of shoulder presentation terminate spontaneously, where, version being out of the question, other accoucheurs would have resorted to embryotomy.

During the two years in which Dr. Kleinwachter was assistant at the obstetrical clinic at Prague, he saw thirty-two presentations of the shoulder and side, of which six terminated spontaneously—one by spontaneous version, five by spontaneous evolution—in all 18'75 per cent.

Except in the case of spontaneous version, in which the side-presentation became a presentation of the breech, the labour terminated by spontaneous evolution properly so-called (spontaneous version being accomplished at the outlet), and sometimes by expulsion of the body of the fœtus doubled on itself; the first process occurred three times, the expulsion of the body doubled, twice. Of these last instances, one merits special notice. The child presented the side of the thorax, the left arm being outside the vulva. Spontaneous evolution was accomplished, though the child weighed 4lbs. 4oz. (4 livres), and the pelvis of the mother was contracted antero-posteriorly. The labour was rapid (ten hours); the mother died on the thirteenth day after confinement, from peritonitis.

After having reported this case in detail, the author makes the following comments. The mechanism of the labour resembled, in its general features, that of expulsion with the fœtus doubled, although the two extremities of the body did not escape simultaneously. The process was like that which one observes at the beginning of spontaneous evolution before the pelvis becomes engaged; but the second stage, the rotation of the child on its transverse axis, did not occur. The expulsion of the child in any other way was impossible, the body of the fœtus undergoing a forced flexion; the flexion was greatest at the base of the neck and the upper part of the dorsal portion of the spine, where it was so marked that the two parts lay parallel; the head was, as it were, driven into the chest, and the face bore the imprint of the bodies of the vertebræ. The arm, which was within the uterus, was extended in a groove formed by the head and coccyx. One favourable condition, which Birnbaum also indicates, was that the back of the child was, at the beginning of the labour, directed anteriorly, from which it resulted that the lower extremities were forced against the body by the pressure produced by the promontory of the sacrum and the lumbar vertebræ; a pressure increased in the present instance on account of the diminution of the conjugate diameter. The rotation of the fœtus on its longitudinal axis, which changed the relation of the back so that, from being directed forward, it looked to the left, then backward, was determined by the projection of the promontory of the sacrum; the child being forced by the strong uterine contractions to occupy the part of the pelvis best adapted to it. This revolution, however, was practicable only because the antero-posterior contraction was slight; a greater diminution, the size of the child remaining the same, would very probably have prevented this, and the subsequent expulsion of the fœtus, doubled, could not have occurred.

The mechanism of such a labour as the one described depends very much on the deformity of the pelvis; with a normal pelvis, we should look for a case of spontaneous version by the breech. The rotation of the fœtus on its transverse axis was prevented by the promontory of the sacrum, the contraction of the conjugate diameter rendering the engagement of the body in the direction of the oblique diameter impossible; flexion of the spinal column could alone permit the termination of the labour.

The other conditions which favoured this labour were the following:—The fœtus lacked two weeks at least of its term, and consequently offered less resistance to the uterine contractions, and was, moreover, sufficiently yielding and flexible to adapt itself well to the shape necessary for its expulsion. These conditions were still farther assisted by the death of the child at the beginning of the labour and by the partial maceration consequent. Again, the position of the child was favourable; the chest, after the prolapse of the left arm, being contracted anteriorly and thus enabled to engage itself more easily in the superior strait. Moreover, the well-marked and decisive pains contributed not a little to the progress of the labour; with feeble pains, other things being equal, embryotomy would have been the only resort. The violence of the contractions was favoured by an early escape of the *liquor amnii*, by pressure on the abdomen and by ergotine.

Finally, the woman was a multipara, and the soft parts were very yielding.

The author has been unable to find in the literature of obstetrics any case like the present; that is, spontaneous evolution in a contracted pelvis. He draws the inference that a moderate degree of contraction in the conjugate diameter offers no obstacle to such a labour if the other conditions favour; the mechanism of the labour is, however, considerably modified thereby.

To the objection that the life of the mother might have been saved by embryotomy, the author replies that the labour was ended in about thirty minutes; it would not have been shortened by instrumental interference, or, at all events, by only a few minutes.

In glancing at the three cases reported by Dr. Kleinwächter, it will be seen that spontaneous evolution is not so rare as is generally believed. The propriety of early interference is likewise questioned, and the teachings of Naegle are not accepted. In his work on "Obstetrics" Naegle says:—

"This intervention of Nature is rare, and occurs under conditions which can be neither anticipated nor looked on with favour by the accoucheur; it is always fatal to the child, and generally presents the gravest risks as regards the mother; the practitioner would be inexcusable who, relying on the problematical powers of Nature, refused to interfere at the proper moment and with the proper means."

In presentations of the shoulder or side, when the waters have escaped at an early stage, one need have no doubt whether the child be alive. The violent compression to which the fœtus is subjected by the uterine walls renders turning impossible; so, if the pelvis be normal, the child, small or premature, the pains strong and continuous, the condition of the mother good, ought not the operator to await the natural progress and termination of the labour? At least the mother would not be exposed to the risk of death by injury to the uterus through the use of instruments. The case is a different one, however, when the child is large; embryotomy would, in that instance, be imperative, the disproportion between the size of the child and the capacity of the pelvis rendering spontaneous evolution impossible, for the mother would probably die before the labour terminated.

## Hospital Reports.

### ST. GEORGE'S HOSPITAL.

#### *Small-pox.*

(Cases reported by DR. JONES in the "Annual Report.")

CASE I.—Sarah M., æt. twenty-five, admitted into Holland Ward on September 28th, for syphilitic laryngitis. She took ten-grain doses of iodide of potassium from the 3rd of October to the 25th of November. After feverishness, headache, and sickness of two or three days' duration, small-pox eruption appeared on the 25th of November. This at first was thought to be due to the iodide of potassium that she was taking. On the following day, as soon as it was decided that she was suffering from small-pox, she was removed to a separate room downstairs, in the basement of the south wing, whence she was removed into the workhouse on the 1st of December. From the time the eruption was noticed, every care was taken to disinfect her bed-linen, bedding, &c.

CASE II.—Sarah C., æt. twenty-five, admitted into Drummond Ward on July 29th, suffering from diseased knee. Eruption of small-pox appeared on the 14th of December. The eruption was semi-confident. Has made a good recovery. Was vaccinated in infancy; vaccine marks of indifferant quality.

CASE III.—Elizabeth H., æt. twenty-three, was admitted Oct. 15th, for strumous ophthalmia, into the Cholmondeley

Ward. Was attacked on November 16th with scarlet fever, followed by albuminuria. Was brought down to the Holland Ward, and placed within two beds of Case I. Whilst still suffering from slight albuminuria she was attacked with small-pox, the eruption of which appeared on December 14th. This and Case II were immediately isolated in the above-mentioned room downstairs. The eruption was distinct. The attack for the first few days threatened to be severe. It suddenly abated. She made a rapid and good recovery. Was vaccinated in infancy; vaccine cicatrices of good quality.

CASE IV.—T. H., æt. forty-two, admitted November 30th, into Fuller Ward, for pneumonia. Was discharged, recovered, on 28th December; re-admitted for slight attack of bronchitis on December 4th. Eruption of small-pox appeared on the next day. The attack was very modified and mild. Was discharged convalescent on 29th January. Was vaccinated in infancy; vaccine marks of bad quality.

CASE V.—J. J., æt. thirty-seven, admitted on December 7th, into Cambridge Ward, for paraplegia of three year's duration. Small-pox eruption appeared on January 5th. This was accompanied with a roseolar rash, which at first was attributed to somewhat large doses of belladonna he was taking. The rash became petechial; and in spite of wine, which was freely administered, he sank on Jan. 8th.

*Post-mortem examination.*—The kidneys were found congested, and weighing fifteen ounces. The tubes were full of epithelium, points of ecchymosis on the peritoneum covering the whole intestines. Outside the theca vertebralis in the dorsal and lumbar regions of the spinal cord there was a thick layer of fat. There was a small, but very distinct to the touch, patch of softening at the termination of cervical portion of the cord.

CASE VI.—J. J., æt. sixteen, admitted 24th November, into Harris Ward, suffering from inflamed ankle. Eruption of small-pox appeared January 7th, semi-confluent. Although a severe attack, he made a good and rapid recovery. Said to have been vaccinated; no vaccine marks can be seen.

CASE VII.—Arthur R., æt. seventeen, admitted November 30th, into York Ward, for enteric fever. Eruption of small-pox appeared on the 7th January, about nine days after he was convalescent from the fever. The attack was very modified. Made a good recovery. Discharged January 26th. Was vaccinated in infancy; vaccine cicatrices of bad quality.

CASE VIII.—Walter H., æt. sixteen, admitted December 7th, into York Ward, for subacute rheumatism. After a course of alkaline and iodide of potassium treatment, purpura appeared on the legs. Small-pox eruption, which scarcely became pustular, appeared on January 7th. Was discharged well on 24th January. Was vaccinated in infancy; cicatrices of bad quality.

CASE IX.—W. F., æt. sixteen, admitted November 23rd, into King's Ward, for chorea. Small-pox eruption appeared on 9th January. Vaccinated in infancy; no vaccine marks visible. The attack was moderately severe. Has made a good recovery. Discharged February 8th.

CASE X.—H. K., æt. thirty-four, admitted November 30th, into King's Ward, suffering from osteo-arthritis. Small-pox eruption appeared on 9th January. The attack was moderately modified. Has made a good recovery. Vaccinated in infancy; cicatrices of bad quality.

CASE XI.—James D., æt. seventeen, admitted November 23rd, Winchester Ward. Chronic disease of ankle. Small-pox eruption on January 9th; modified attack. Has made a good recovery. Vaccinated in infancy; vaccine cicatrices of bad quality.

CASE XII.—William C., æt. twenty, admitted December 21st, Fitzwilliam Ward. Chronic inflammation of knee. Small-pox eruption appeared on January 9th; very slight attack. Vaccinated in infancy; vaccine marks of very good quality.

CASE XIII.—Christiana S., æt. twenty-three, probationer nurse. Small-pox eruption, which became confluent, appeared on January 9th. Died on the eighth day. Vac-

inated in infancy; had three vaccine marks of moderately good quality.

CASE XIV.—Ellen C., æt. nineteen, admitted November 2nd, Queen's Ward. Extensive mitral disease with dropsy. Small-pox eruption, which was very modified and distinct, appeared on January 9th. Died, chiefly of the heart disease, on January 31st. Vaccinated in infancy; vaccine cicatrices of excellent quality.

CASE XV.—Mary H., æt. twelve, admitted December 12th, Drummond Ward. Suffering from knocked-knees. Small-pox eruption, very modified, appeared on January 9th. Discharged convalescent, January 31st. Vaccinated in infancy; vaccine cicatrices of excellent quality.

CASE XVI.—Mary G., æt. twenty-nine, admitted December 15th, Burton Ward. Phlegmasia dolens. Eruption very modified, distinct, on January 11th. Discharged February 6th.

CASE XVII.—Amos W., æt. forty, one of the carpenters of the hospital. Small-pox eruption appeared on January 13th, attack very modified. Has made a good recovery. Was vaccinated in infancy; two vaccine marks of good quality. Said to have had small-pox twenty years ago.

CASE XVIII.—Mathew B., æt. fifty-two, admitted November 17th, Oxford Ward. Fractured arm. Small-pox eruption, very modified, appeared on January 14th. Discharged well, January 29th. Vaccinated once; vaccine marks very good.

CASE XIX.—Florence B., æt. nineteen, admitted Dec. 14th, Crayle Ward. Eczema. Small-pox eruption, which was distinct, appeared on January 14th. Was re-vaccinated on the same day. The attack was rather severe. There was no trace of the re-vaccination on the seventh day. Was vaccinated in infancy; one vaccine mark of bad quality. Has made a good recovery.

CASE XX.—Frank D., æt. eighteen, admitted December 30th, Oxford Ward. Fractured leg. Eruption appeared on January 15th; attack slight. Was vaccinated in infancy; vaccine marks of bad quality.

CASE XXI.—Elizabeth S., æt. twenty-four, admitted January 12th, suffering from febrile symptoms. Small-pox eruption, distinct, appeared in a few hours after admission; attack slight. Vaccinated in infancy; one vaccine cicatrix of bad quality. Was vaccinated six years ago, but did not take.

CASE XXII.—Ellen H., æt. fifteen, admitted Feb. 4th in a comatosed state, and suffering from congestion of both lungs. The eruption appeared on the same evening as she was admitted. There was suppression of urine for two days. As soon as the eruption was well out, the head symptoms began to improve. The attack abated about the sixth day. Has made a good recovery. She was vaccinated in infancy; one vaccine cicatrix of good quality.

CASE XXIII.—David E., æt. twenty-five, admitted February 8th. A week ago was thrown off his horse, and in the fall he came down on his back; suffered considerably from pain in his back, which he attributed to the fall, until he was admitted. On admission, besides the pain in the back, for which he came from Worthing to the Hospital, he coughed bloody sputa, and had other evidences of congestion of lungs. Small-pox eruption appeared the day after admission, accompanied with roseolar rash, which became petechial. He became very delirious and tremulous, and sank on February 13th. On *post-mortem*, the upper lobe of right lung was intensely congested, while the whole of lower lobe was in a state of red hepatisation; the lower half of left lung was intensely congested. The heart was semi-contracted, and contained a decolorised clot. The kidneys weighed sixteen ounces, and were very congested. The cortices on section were of extremely coarse appearance, and many tubes were blocked with epithelium.

CASE XXIV.—George K., æt. forty, admitted October 16th into Oxford Ward, for fracture of leg. Was sent to the Wimbledon Convalescent Hospital on December 7th. Small-pox eruption, which was confluent, appeared on

ember 17th. He is said to have had a slight mark of vaccination on each arm.

CASE XXV.—Michael S., æt. forty-eight, admitted October 26th into Harris Ward, and afterwards removed into Hope, for pyelitis. Discharged December 28th. Slept that night at Vauxhall-bridge road; went home to Fellday, near Dorking, on the 29th. Eruption appeared on either the 6th or 7th of January. He died of confluent small-pox on the 12th. It is said that he was vaccinated when young, but no notice was taken of the marks. I am indebted to Mr. Jardine, of Dorking, for some of the particulars of this case.

CASE XXVI.—Sarah F., æt. nineteen, admitted October 12th, Cholmondeley Ward. Discharged December 19th, 1870. Small-pox eruption appeared December 29th. Although the attack was said to have been very severe, she has made a good recovery. She was vaccinated when she was two years old.

CASE XXVII.—John T., æt. three, admitted November 2nd, Princess Ward. Stone in the bladder. Lithotomy performed on November 15th. Some erysipelatous swelling of prepuce appeared after the operation. On January 3rd, was seized with sore throat, which was supposed to be due to hospital air. Mother was advised to take him home. Small-pox eruption appeared on January 4th or 5th. Died January 11th. *Was never vaccinated.*

## Transactions of Societies.

MEDICAL SOCIETY OF LONDON.  
OCTOBER 16, 1871.

DR. ANDREW CLARK, F.R.C.P., President.

AFTER a few words of cordial welcome to the Fellows, the President said that he was happy in being able to congratulate them on the prosperity of the Society which had never been better off. The Fellows numbered 400; of these 180 were non-subscribers. The Honorary Treasurer, Mr. John Gay, had a balance of £211 in his hands; while the Fothergillian Fund has risen from £500 to nearly £1,000. The Society's Freehold, No. 3 Bolt court, which was bequeathed by Dr. Lettsom, was let for £50 a year, but as the present lease would expire in another year it was estimated the Society would derive at least £100 a year from this source. How was this property to be kept up? By maintaining and, if possible, in improving the work. By trying our communication by this test. Do they add to, correct, or confirm what is already known? By aiming in all our work at precision, by making it compendious and practical, and in recording results of therapeutical experiments—to cultivate the spirit of good fellowship, and to find out in one and other what is worthiest and best, and so working with singleness of heart and purpose it cannot be but that our work will be fruitful in all measures of good. In speaking of the character of our work, he would refer—1st. To the early history of disease, say of phthisis, it was by the co-operation of Fellows of such a society as this that a perfect knowledge of such a disease could be had. 2nd. *Therapeutics*, then, was a want of faith, and a want of precision in the use of drugs a great want of reliable knowledge. Such important investigations as these might well be made by committees from time to time, and means might be furnished from the surplus Fothergillian Fund. The second way to increase the prosperity of the Society was for each Fellow to endeavour to induce another to join. It is in such a society as this that we get fresh knowledge, our errors corrected, our doubts resolved. It is here that a man is delivered from his own crotchets, follies, and ignorance, secured from one-sided views and brought face to face with every side of the problems which he studies. A man does not know what he knows or what he does not know till he has taken an active part in the debates of such a society. The President then alluded to the great loss the Society had suffered in the death of the late Dr. Hyde Salter, who had been three years Secretary to the Society, and had discharged the duties attached to the office in a most exemplary manner. He had accepted the Lettsoman Professorship, but finding his health failing he resigned the

appointment early in the year. Dr. Clark then gave a description of his (Dr. Salter's) case which will appear hereafter.

DR. RICHARDSON then read a paper on

THE POSSIBILITY OF DESTROYING ANIMALS INTENDED FOR HUMAN CONSUMPTION WITHOUT THE INFLICTION OF PAIN.

After reviewing the various means employed in the execution of this humane project with partial success, he recommended the following vapours:—

1. Hydramyle and bichloride of methylene.
  2. Carbon disulphide and methylene bichloride.
  3. Chloroform or methylene and coal gas. In sleep all sensibility is destroyed in 50 or 100 seconds.  $\text{Zij}$ . is poured into demette in a conical inhaler—the animal does not struggle—the butcher kills in the usual way—bleeding follows.
1. Primary syncopal convulsion (after loss of 40 ozs. of blood).
  2. Fatal convulsive paroxysms (after the loss of 10 ozs. more).

The heart ceases to play. During narcotism the primary convulsion is suspended or much reduced in force. The second convulsion (an entirely reflex and painless phenomenon), insensibility, is quickly produced: no odour or taste is left. An ingenious apparatus was shown to contain the narcotic vapour and to allow coal-gas to fall through. For oxen a number of chambers could be devised with swinging doors, through which oxen could be drawn on trucks by means of an endless chain. The chambers to be filled with the narcotising vapour. Animals could pass through the lethal river of vapour and be made oblivious of death at the rate of 60 per hour.

MR. JOHN GAY, F.R.C.S., then read a paper on

HYPPO-VENOSITY OF THE LOWER LIMB,

of which the following is an abstract.

The term *hypo-venosity* is used to express a condition of the limb in which there is a deficiency in the veins belonging to the saphenous system: as *hypo-venosity* might be used to express the opposite condition, or that in which there is an excess in the development of these veins, even to varicosity.

The characteristic features of a *hypo-venosity* limb are the reverse of those which obtain in a limb affected with *hyper-venosity*; for, whereas in the latter, especially with varicosity, the limb is usually lean, and the outlines of bone, muscle and tendon, are, as a rule, sharp and well defined; in the former, these outlines become gradually effaced, the skin becomes of a dusky colour, the whole limb dense or brawny, and muscular action difficult and painful. With the exception of sometimes, it may be, a few dilated or varicose venous twigs below the ankles, or on the dorsum of the foot, there is scarcely a vein to be seen, except as it may be, here and there as a thin blue line, which exercise or heat fails equally in filling.

The disease is advanced by rest and elastic stockings, the remedies usually employed; and, with its advance, the subdermoid fat layer becomes denser and loses its elasticity; whilst its remote causes are any disease of those vessels of an active or passive character, such as phlebitis, especially in its gouty or rheumatic forms, insufficient muscular exercise, systemic asthenia, &c. Degeneration and consequent incompetence of the saphenous veins and their branches is its direct or exciting cause; secondarily, it is presumed, the deep trunk veins become dilated, their valves partly inert, and fatty deposit and degeneration take place in the muscles and their connective tissues.

The grounds for this interference are; (a) that functional deterioration of the saphenous system, though thickening, atrophy, retrecissement, or thrombus, is an occasional pathological fact; (b) and that saphenous inefficiency as shown by a varicose condition of the venous radicles,—tegumentary or figurative varicosity—as well as by a dusky colour of the skin, otherwise than from melasma or skeleroderma, are habitually associated with and indicate dilatation of the deep trunk veins. (These facts I observed in the course of dissections made some years since, with a view of elucidating the subject of varicosity.)

Throughout the systems of organic and muscular life the venous system is double—the *superficial* and *deep*, or the *main* and *complementary*; the former playing to the latter the part of a waste-pipe, or compensating system, ready to relieve it when its vessels are unduly filled. The deep veins, *i.e.*, those which are radically interwoven with the organs of vegetative and animal life, constitute the *real* venous system, therefore,

the current through his veins, in the healthy performance of the double circulation, is maintained by a combination of forces, of which voluntary muscular action is not a necessary co-efficient, since it would go on with the limb at perfect and continued rest. The current through the complementary veins, on the other hand, derives its chief importance from the fact of its receiving, in the limbs more especially, its principal impulse from voluntary muscular action. In case its vessels become inefficient, the surplus quantity of blood, due to muscular exercise, is poured into the deep veins with a force that, as the result of this abnormal diversion, is expended on their coats, and results in dilatation, valvular incapacity, muscular deterioration and other changes yet to be noticed. The forces which determine the returning current of the blood are complex: the principal of which are the heart's action, arterial elasticity, and the influence of the nervous system. These are factors, each to a certain extent only; whilst experiments show that each may separately be cut off, and yet the blood will find its way back to the heart. Moreover, the blood will pass from the arteries into the veins without the aid of any of these forces. The blood passes into the femoral vein if the corresponding artery is tied, its flow being only retarded; and, according to the experiments of Dr. J. Reid, as relates to the nervous system and muscular tissue, it is clear that the only ascertained final causes of all endowments bestowed on nerves in relation to muscles is not to make muscles irritable but to subject their irritability in different ways to the domain of the acts and feelings of the mind, and I might add to the exigencies of the organism. To complete the sum of the required forces, another has been hypothesized the "capillary" force. Can such a force be shown to exist? I made the following experiment on dogs some few years since in the presence of many members of our profession. The whole of a dog's thigh was enveloped in ligature with the exception of the femoral artery, so as to permit of the free ingress of blood into it, but completely to prevent its exit. The result was that the whole of the saphenous system to its minutest capillary vessels, and the deep trunk veins were filled to their utmost point of indurance, but there was no corresponding sanguineous repletion of muscular tissue. It showed no signs even of congestion. This, with another ascertained fact, viz.:—that after death the temperature of the body may rise and muscular contraction occur, giving rise to its well-known "hum" (Drs. Haughton and Collongues), and the disposition of the minute capillaries in relation to muscular tissue (which through the kindness of Dr. Dempsey I hope to be able to demonstrate at the next meeting), together go far to prove the existence of such a force in a condition of perpetual activity; that it exists in connection with muscular tissue or sarcode—that organic molecular action, perhaps, which exists in all sarcode, from that of the amoeba to the higher organisms—and that to it the venous current is mainly due; that in fact, as an agent in the circulating system, it is to the capillary, very analogous in some respect to what the heart is to the arterial system. As this department of the venous system belongs to vegetative life, so embarrassment to the current of blood through it, results in defective elimination of the hydro-carbons and their allies from the tissues implicated; and hence solid oedema, super-facially, fatty deposit and degeneration, sub-facially and ultimately elephantiasis or a disease closely akin to it.

As the *deep* or *main* system of veins is thus associated with the nutritive processes, so the *superficial* or *complementary* is essentially eliminatory, for it is from those veins in the lower limb that dropsical effusion takes place. (Edematous fluid is chiefly and usually solely superficial, and it is not improbable that in other dropsies as of the pericardium, pleura, or peritoneum, the fluid escapes from veins of the same class, viz., from those of the complementary system.

The disorder described is due then to inefficiency in the saphenous system of veins, followed by deep vein dilatation and embarrassment.

The treatment is the reverse of that ordinarily employed, viz.: an entire freedom of the limb from all compresses, enforced walking exercise, begun in moderation and periodically increased, hot applications, especially hot sea-water to the limb, and it may be the internal administration of the liquor potassæ:—in short, by the use of all those measures, hygienic and therapeutical, which can, on the one hand, restore the circulation of the limb upon the principal that its right use is its stimulus to health and perfection; and on the other, relieve it of its superabundant fat.

## OBSTETRICAL SOCIETY OF LONDON.

OCTOBER 4TH, 1871.

DR. BRIXTON HICKS, F.R.S., President, in the Chair.

JOHN M. TAYLOR, M.D. (Scarborough), was elected a Fellow of the Society.

DR. BARNES presented to the Society, on behalf of Dr. Boddaert, of Brussels, the lever employed by Dr. Boddaert, also a memoir on the rational use of forceps and lever by the same gentleman. Dr. Barnes then drew attention to the form of the lever, which was a solid bar, nearly straight, and without fenestra. Such a bar could only be a lever, and in no sense a tractor.

DR. BARNES also exhibited a specimen of an ILLIAC ARTERY OBSTRUCTED BY A CLOT.

The case was described by Mr. Williams, of Truro. The subject was seized during an abortion with prostration, coldness, failure of pulsation, and gangrene of the leg of the side on which the artery was plugged.

MR. SPAULL exhibited

A FÆTUS THE SUBJECT OF HYDROCEPHALUS.

The child presented by the breech, and the head had to be perforated.

MR. MITCHELL said he had met with several cases of the kind in his practice. In every case he had perforated the head and delivered the child by the forceps.

DR. MURRAY thought that in such a case as that related to the Society much diagnostic information could be obtained by placing the hand on the lower part of the abdomen and feeling the unusually large size of the uterus after the birth of the extremities and body of the child. The possibility of the existence of twins should be remembered.

The PRESIDENT read a paper on the INTERMITTENT CONTRACTIONS OF THE UTERUS DURING PREGNANCY; THEIR PHYSIOLOGICAL-VALUE AND ASSISTANCE IN DIAGNOSIS."

He showed, as the result of eight years' constant observation, that the habit of the uterus was to contract at intervals of from five to twenty minutes, and then to relax. These contractions, he said, lasted about three or five minutes, although under circumstances of irritation they might continue longer, and even, in diseased states of the ovum, were almost continuous. Only one apparent exception had been noticed—namely, in a case of paraplegia, in which the contractions were not noticed. They were observable as early as the third month of pregnancy; indeed, as soon as the consistence of the uterus permitted. They were not owing to the irritation of examination, for as frequently as not the uterus would be found hard on first handling it, and then shortly to relax. After describing the physical state of the uterus and its contents during these conditions, Dr. Hicks alluded to the value of these contractions physiologically. He thought at least two advantages were derived from them: the one to supplement the heart's impulse in a part remote from its influence; the other to assist the ultimate disposition of the fœtus. He then proceeded to discuss at length the assistance these contractions gave the practitioner in the diagnosis of extra-uterine from uterine tumours, of uterine tumours from pregnancy, and of extra- from intra-uterine pregnancy.

DR. BARNES called attention to the work of Dr. Tyler Smith, in which the peristaltic movements of the pregnant uterus were well described, not only as forming the basis of the expelling force during labour, but also as diagnostic of pregnancy.

DR. HICKS said the extract quoted from Dr. Tyler Smith's work had escaped his notice. But Dr. Tyler Smith had referred to the peristaltic movements as the result of external excitation, while those which had been just described occurred without any such.

DR. COPEMAN, of Norwich, related three cases which he had met with in practice; the first being one of induction of premature labour on account of excessive vomiting, the second a case of large fibrous polypus of the fundus uteri, and the third a case of proclivencia uteri in a maiden lady.

DR. BARNES agreed with Dr. Copeman that the introduction of a bougie or catheter into the uterus was the best mode of provoking labour: but, like all simply provocative means, it could not be depended upon to complete labour. Accelerative means were often necessary. The best of these were rupture of the membranes, dilatation of the cervix by the water-bags, turning, and the forceps.

DR. PROTHEROE SMITH referred to an instrument shown him by Dr. Tarnier, of Paris. It consists of a metal grooved director about eight inches long, carrying a tube of india-rubber, thin at its distal extremity. This is introduced into the uterus, towards the fundus, separating the membranes. It is then distended with water, so as to form a bulb-shaped bladder, when the metal director is withdrawn. Uterine action usually sets in within a few hours.

DR. PLAYFAIR generally used a simple catheter, which he passed between the membranes and the uterine wall; but on more than one occasion he had seen it fail. The uterus was occasionally roused into activity with great difficulty, and this probably depended on some peculiarity in the individual case.

DR. BRUNTON had induced premature labour successfully nine or ten times by injecting warm water into the uterus. He had, however, now given up that method, both on account of the danger said to attend its use, and because in one case it proved a total failure. He now used a bougie (No. 12) in which no eye had been cut.

DR. MURRAY expressed his belief in the value of the plan recommended by Professor Lazarewitch, of injecting water into the uterus. He had nothing to say against the use of the catheter, except that it had occasionally failed to bring on labour.

The President said that the safety of the child depended on two conditions—viz., the rapidity with which the uterus came into action, and the freedom with which the child passed through the os uteri. Dilatation of the cervix certainly answered the latter requirement excellently.

DR. WILTSHIRE suggested the desirability of inducing premature labour at a period in pregnancy which in respect of time corresponded to a menstrual epoch.

DR. ROGERS had, early in his career, been accustomed to puncture the membranes high up, so as to save some of the liquor amnii, having first dilated the cervix with sponge tents. Of late years he had used a long catheter with an opening at its rounded extremity. This had been successful in all except in two cases, and in these he found it necessary to inject some water through the catheter to excite uterine action.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, NOVEMBER 1, 1871.

### THE MEDICAL ASPECT OF THE FRANCO-GERMAN WAR.—No. I.

WHEN, early in the autumn of 1870, the armies of France and Prussia were respectively put in motion, all on this side the Channel knew and felt that great military events were about to take place, events from which valuable lessons

could be drawn by insular England. It is said, however, that the two great powers in question received coldly the proposals of the British Government to send to their Head Quarters military officers to study and note, for the benefit of John Bull, such improvements in their systems as could be adopted with advantage, or such defects as should be avoided in the plan of reorganisation of his own small force which, for the twentieth time within the present generation was then being discussed. But no similar objection was urged against the proposal to send Medical men, either as commissioners, or as delegates of the societies established under the Convention of Geneva, to follow the armies, and minister to the necessities of the sick and wounded. Accordingly, some military Medical officers, acting under the authority of the War Office, were attached to the French and Prussian armies in the former capacity; others joined a number of civil practitioners, who, under the auspices of the National Society in London, were sent with the ambulances provided by British charity.

Of the experience gained by the former the public may be said to be virtually in ignorance, for beyond a brief allusion in papers read before a society here and there, or casually noticed in a periodical, the fruits of their several missions may be said to still incubate, or addle, as the case may be, in the pigeon holes of the War Office. The Society for Aid to the Sick and Wounded in War,\* true to its professed object, has, for the benefit of future sick and wounded published the results of its notes, as well as reports of the surgeons employed under its auspices, and it may be at once observed that, if here and there a few defects and indications of friction are apparent, the volume is, perhaps, one of the most remarkable monuments furnished in this, or any other age, of true charity exerted upon a large scale. Not only did the agents of the society minister to the professional requirements of the sick and wounded in hospital but they distributed food and money in ways best calculated to be of benefit. Thus, at some places, as Forbach near Metz, they established restaurants for the distribution of food and stimulants to those being transported by railways, and the donations made in money by the hands of Colonel Lloyd-Lindsay to both Prussians and French, need only be alluded to and the question asked:—when on any former occasion was such a sum as £40,000 bestowed upon more needy subjects? Look, also, at the maps which illustrate the report, and let us ask when before has ever the continent of Europe been apportioned as on the present occasion, the work done by the society having been thus divided (p. 21), 1. Aid in Germany; 2. Work in North Eastern District of France; 3. in the Northern district; and 4, in the Western district.

The British National Society for aid to the Sick and Wounded, and the French *Société des Secours aux Blessés*, constitute together the most extensive organisations which have yet been formed under the Convention of Geneva. To *M. Henri Dunant* is due the honor of being the founder of this convention, and it is due to him that, in an article such as this is intended to be, the fact should be stated and acknowledged. It was he who drew the attention of all Europe to the inadequacy of purely Medical organisation to meet the requirements of war. What he so frequently urged, with more especial reference to *Solferino*, has received ample confirmation in this report, and not only so, but the necessity is further shown of having, under

\* See the “Report of the Operations of the British National Society for Aid to the Sick and Wounded.” London, 1871.

the convention itself, an organisation ever ready to take the field whenever an emergency, similar to that presented by the late war, may arise; for the time has not yet arrived when we are justified in believing that wars shall cease. As matters formerly were, the condition of the wounded would have been deplorable, indeed, had it not been for the societies under the "Red Cross." The army of the Loire, for example, is stated, (p. 17), to have been "destitute of the barest necessaries for preserving life." "The French surgeons had neither chloroform, nor medicines, nor surgical instruments, and many of the amputations had to be performed with butchers' knives, and common saws." "There had been no time to organise a proper Medical staff, and the impracticability of obtaining supplies from Paris, and the interruption of communication," rendered it impossible to obtain the necessary establishment. Many more examples of the same kind might be related.

It could hardly have been expected that any organisation however good and philanthropic its objects, could have been got together, as the National Society was, hurriedly, and in the face of a great emergency, without a few blemishes appearing. Those blemishes were inseparable from it under the circumstances, but may in a great measure be avoided in future occasions, or at any rate, reduced to their minimum. For example, the *brassard* and red cross were, in some instances, assumed by persons who had no right to them, in others houses were nominally given over as ambulances, and distinguished by the *Red Cross* flag, not merely for the purpose of receiving sick and wounded, but for the protection of the property of the owner; nor are the *employées* of the societies altogether free from the suspicion of having conveyed information between the belligerents.

But if some abuses crept in to the working of these societies, complaints have been made against one at least of the armies concerned of having refused that protection to establishments under them which had been agreed to by the Convention of Geneva. It is asserted that the French Government several times supplied the Anglo-American ambulance with military infirmiers, but as soon as they got to work, the Prussian authorities would send up a file of soldiers and march them off as prisoners of war. This happened several times. On one occasion they marched off forty-seven infirmiers (p. 104), and yet in the German army soldiers fully armed and equipped for ordinary military duty wore upon their arms a very large and conspicuous *brassard*, with the red cross. On the 1st of September the Prussians took possession of the building occupied by the English ambulance, but decamped the same evening, on a formal protest being made by the surgeons. At Artenay, on 10th October, a similarly unwelcome visit was made. "In the evening some Prussian officers came to inspect the ambulance, and after eating the dinner intended for ourselves, took up their quarters in the rooms prepared for our use, and refused to consider they were breaking the Convention of Geneva." Those very free and easy visitors were not to be easily got rid of. They took their comfort while they could get it cheap, and on their departure the following morning, carried away with them some of the provisions of the ambulance intended to succour their own wounded, as well as those of the *enemy* (p. 168). Whether the circumstances were ever reported to the higher military authorities does not appear. Let us believe that had a report been made the offenders would have received their merited reward.

Having made these preliminary remarks, let us now see what are some of the points in which valuable information is to be found in the Report.

*Hospital Buildings.*—The unsuitability of many of the buildings selected as hospitals is dwelt upon, as, indeed, the subject has been by the greater number of army surgeons, from the days of Sir John Pringle, downwards. "The most spacious palaces," so we read at page 22, "are less suited for the care of badly wounded, even than the temporary buildings erected of wood or canvas." Although every practicable care was bestowed upon the selection of suitable *bulidngs*, yet the great want seems to have been in regard to means of ventilation. "The great defect is, that there is no ventilation, except from the windows, which are almost invariably closed" (p. 58). Both Germans and French, in fact, have ideas on the subject of fresh air very different from those entertained by the medical profession in England. In French houses the form of the window frames renders them unsuitable for purposes of ventilation; thus they open longitudinally, like ordinary ones, instead of transversely, as do ours in England. Capt. Galton especially dwells upon the deficient means of ventilation being provided in some of the buildings seen by him. Nor were the surgeons in all instances opposed to the admission of fresh air. One in a hospital at Mannheim said that he would rather keep his wounded in the open air till December, than place them in such buildings, and, indeed, so partial to pure air was he that he caused "many of his wounded to be carried in their beds by day into the adjoining meadow" (p. 58). He had doubtless seen or read of the benefits from fresh air derived by the wounded in the American war. With regard to the suitability of particular buildings for hospital purposes, it is very properly stated that no "more disastrous idea can take possession of men's minds than that sick and maimed people ought, on grounds of humanity, to be packed into churches, barracks, and other unprepared buildings with as little delay as possible. This error has slain its tens of thousands in all wars;" and, it is added, "even in specially constructed and well-managed civil surgical hospitals, every surgeon knows how difficult it is with all his care to prevent the invasion of hospital diseases. In extemporised war hospitals they have been too often invited to enter" (p. 172).

*Huts* as hospitals were very extensively used in Germany as they were in France. When due attention is paid to their construction, they are doubtless well suited for wounded men, but they may be so faulty in construction as to have all the drawbacks of imperfectly-ventilated stone buildings, as indeed seems to have been the case at Mannheim.

*Tents* were used in Paris to a considerable extent for the accommodation of the wounded. Different descriptions were employed, but by far the most appropriate were those of the American Ambulance. Dr. Marion Sims states that a number of tents were put up in connection with the Ambulance of the Caseine d'Asfeld at Sedan, because "the Prussians wanted the College Ambulance in the town, and so they sent its 156 sick and wounded up to our hospital, putting some of them in the hospital, but most of them in the tents" (p. 103). Perhaps in this case the object with which tents were erected was selfish, but at any rate the process did not take long time to complete. Dr. Sims had asked for half a dozen tents to be put up. He was amazed to see with what alacrity it was done. "But they did not stop with the

six ; they went on, and covered over two or three acres with tents to the number of thirty-six in spite of our remonstrances." It was, however, fortunate for the wounded themselves they were treated in tents. Their chances of recovery under such circumstances were always better than of those treated in huts, and infinitely greater than of those treated in the more pretentious permanent buildings.

### INNOCENT ADULTERATIONS AND THEIR RESPONSIBILITIES.

It is a satisfaction to observe that Dr. Lethby's view that adulteration is not a fraud or to be tolerated as long as the adulteration is not noxious to health, is repudiated by a body of traders amongst whom it has been the general impression that adulteration is rife. We have heard a good deal about effervescing citrate of magnesia made up with tartaric acid and washing soda, and such practices have been defended in high pharmaceutical places as innocent and unavoidable. Our view has always been that the buyer ought, in common honesty, to have what he pays for. Let him pay for and have a mixture of mustard, bath-brick and turmeric instead of real mustard ; or of sugar, potato, starch and cocoa instead of real cocoa. He will, in so doing, have of course an advantage on the score of economy, and he may very rationally think that a cheap mixture will do as well (as tea-dealers say) for schools, hotels and charitable institutions as the genuine article. If he holds that opinion he ought certainly to have liberty to gratify it ; but if he has a predilection for the unsophisticated article he surely ought to be allowed an equal liberty. Mr. John Bright considers that it is the buyer's business to look sharp, and if the trader can outsell him by putting starch into his cocoa, or turmeric in his mustard, he is quite right in doing so ; but Mr. Bright must imagine that all housewives are analytical chemists, or he would not talk such bad sense and worse morality.

Reverting to our text, we notice that Mr. Davies, the President of the Liverpool Chemists' Association, in his Inaugural Address last week, spoke for his own trade in denunciation of Mr. Bright's policy. With reference to adulteration, he said nothing would put it down until the seller was made responsible for what he sold, whether the adulteration was of an injurious character or not. If the seller was innocent of the knowledge that the article was adulterated, let him have a remedy against the manufacturer. It was a disgrace that buyers should be compelled to question a dealer as to the purity of his goods. From experience he was of opinion that in pharmacy actual adulteration was not much practiced, although in some districts inferior qualities of goods were sold. We wish Mr. Davies could say as much for the pharmaceutical supply of Irish Unions, where flour of sulphur means three parts gypsum, and tincture of cardamoms has for its menstruum methylated spirit. He is quite right, however, in his policy, for it will be hopeless to attempt to check trade frauds until some Government is sufficiently independent of the small shopkeeper to make him responsible to the customer, and the manufacturer responsible to him, and to take the onus of prosecuting the delinquent off the shoulders of the person cheated, and put it in the hands of a paid Government officer.

## Notes on Current Topics.

### The Female Medical Students.

On Saturday a meeting of the *Senatus Academicus* of the University of Edinburgh was held for the purpose of considering what steps should be taken in regard to the admission of the female medical students to the examinations. A memorial was laid on the table from the Lord Provost of Edinburgh and others, the Executive Committee for Securing a Complete Medical Education to Women in Edinburgh, along with the opinion on the subject by the Lord Advocate and Sheriff Fraser. The opinion was to the effect that, according to the regulations, women should be "allowed not merely to qualify themselves for the ordinary professional examinations with the view to obtain a medical degree in the University, but also, when so qualified, to be admitted to these examinations." A letter was also read from the lady students, in which they say, "The medical faculty must all along have been perfectly aware that in the ordinary course of study our first professional examination would become due at the end of two years after our first matriculation, and yet no official notice has ever been given to us that objections would be made to our admission to this examination ; and that, had any such objection been officially intimated to us, we should many months ago have made application to the *Senatus* to direct our admission to such examination. That in the absence of all notice to the contrary, we have, for some months past devoted ourselves to diligent preparation for this special examination, and that we shall be, placed at the greatest disadvantage if we are not now allowed admission to it. That we have already paid our fees for the examination, and that the ordinary tickets of admission have been granted to us as a matter of course. We therefore beg thus to lay before the *Senatus* our claim to admission to the ensuing examination, in respect of the considerations we have enumerated, and request that, as a matter of good faith towards us, matriculated students of the University, they will accordingly direct the Medical Faculty to admit us in the ordinary manner." After a long discussion the *Senatus* adopted a resolution to the effect that no further difficulties were to be placed in the way of the ladies as regarded either matriculation or preliminary examination.

### The Spiritualists Exposed.

SPIRITUALISM has received (says the *Globe*) another blow by the searching investigation it has undergone in the *Quarterly Review* just issued. No more crushing answer to all the "revelations" made by the London Dialectical Society could be desired. The general inference from the writer's arguments seems to be that in course of time the whole theory will have so exploded that it will be classed among such "epidemic delusions" as the orgies of witches, which two centuries ago enlisted the most steadfast belief. This is no hasty conclusion formed from a simple incredulity in the existence of any supernatural agency. The investigations and asseverations of the best authors—of Dr. R. Hare, the American Professor ; of the Rev. R. W. Dibdin, of Robert Houdin, and others—have been examined, and their theories tested by argument, analogy, and exposure. By way of illustrating the argument that movements which have become mechanical

by habit may be performed involuntarily and unconsciously, it is related on the authority of an intimate friend of the late Albert Smith that he frequently went through his performance of "Mont Blanc" so mechanically as to be quite unconscious of what he was doing, his mind being otherwise occupied throughout. The prestidigitateur Robert Houdin also states that he trained himself to read a book attentively whilst keeping four balls in the air. On similar grounds, it is assumed that the tilting of a table in response to questions put to it is due to the downward pressure of the hands laid upon it. Opposed to this supposition, the writer observes:—"We have, indeed, been gravely assured by a lady of unimpeachable veracity that a table in her own house, with no person near it, on being asked her age, 'lifted up its leg and struck forty-two,' the correct number of years—a result that so appalled her that she sold the table forthwith. But on our hinting a doubt as to whether she had quite correctly remembered the circumstances of the case, which had happened some years previously, she promised to consult some notes she had made at the time; and a few days afterwards she honestly told us that there was one trifling mistake in her previous account; for that she and her friends, instead of being, as she had thought, on the other side of the room, had their hands on the table. The fact that the table had rapped out her age, and that she had parted with a piece of furniture which could not be trusted to keep so important a secret, remained on record."

Hospital Certificates.

SOME time ago we called attention to the impropriety of hospital committees imposing on medical men the trouble of filling up elaborate forms. We instanced the National Hospital at Ventnor as an offender in this matter. We do not know if they have made any reform; but we now proceed to enter a protest against the form sent out by the Brompton Consumption Hospital. It is really most inconsiderate to ask men to spend their time in filling up lengthy certificates that are quite useless, as the patient has afterwards to be examined by the hospital physicians. It is becoming quite a nuisance, and we call the attention of the staff to the practice as one they should discountenance. During the last few weeks we have been pestered by shoals of forms, and we say that any medical man who would return one filled up merely with a general certificate of fitness, would probably lead to a consideration of the subject, and thereby confer a benefit on his brethren.

We append the letter and inclosure sent to a patient by the Brompton Secretary as a proof of what we say:—

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON, LONDON, S.W.

Reg. No.,

1871.

Not to be used for Begging Purposes.

To

I have to inform you that a Letter of Recommendation having been this day received by me, your name has been duly placed on the books for admission as an In-patient in your turn, if your case be found by the Medical Board to be a suitable one for this Hospital. You must now request the Medical Gentleman who is attending you to fill up the enclosed Certificate, and return it *direct* to me. If the same be satisfactory I shall not fail to send you, as *early* as possible, notice of the day

and hour when you must present yourself for examination, and admission, if approved. It may however be about eleven to fourteen weeks before you are summoned, owing to the number of applicants already on the List.

HENRY DOBBIN, *Secretary.*

NOTICE.

Patients must bring with them a change of linen, a towel, a pair of slippers, and a knife, fork, and spoon.

They will also have to provide for the washing of their personal linen; and for their journey expenses to and from the Hospital.

The Committee earnestly request that the Medical Attendant will furnish an *accurate statement* of the case, which will be regarded as strictly confidential.

MEDICAL CERTIFICATE.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

Name of patient? .....  
 Address? .....  
 Occupation? .....  
 Age? .....  
 Nature of disease, &c\*.....  
 How long disease has existed? .....  
 If Consumption, mention the stage of the disease, and whether the case is likely to derive *permanent* benefit from treatment in Hospital. ....  
 If the patient has been prevented from following his or her occupation, state for how long? .....  
 If the patient has been confined to bed, state for how long, and whether wholly or partially?.....  
 Whether equal relief could be afforded by medical treatment as an Out-patient? .....  
 Signature of Medical Attendant. ....  
 Date. ....  
 Address.....

\* State here whether Disease of Heart, Bronchitis, Pneumonia, Pleurisy, or Consumption, &c.

N.B.—The Medical Attendant signing this Certificate is particularly requested to forward it *DIRECT* to the Secretary at the Hospital immediately after it is filled up.

Public School Reforms.

A WRITER, well-known in sanitary circles, under the signature "M. A. B.," has issued a pamphlet on this subject, which is well worth the attention of all who have boys or girls to educate. Some portions of the pamphlet have previously appeared in various periodicals, but are none the less worthy of reproduction, for they touch upon points of the deepest interest. Of this we may be sure, that sanitation at most of our schools is at a low ebb, and all who endeavour to stir the authorities to do their duty in such matters, deserve the hearty support of our Profession.

The question of university athletics is touched by "M. A. B." with a discriminating pen.

Homœopathy at Southampton.

GLOBULISM is triumphant for the present at Southampton, there being no legal reason for annulling the election of a homœopath by the guardians (?) of the poor. So we suppose paupers must put up with the will of their guardians, who impose their own follies on those for whom they are responsible. *Fiat experimentum in corpore vili* is, perhaps, the motto of the guardians. We should wish to see them carry it out by keeping the globules for themselves.

### Dr. Prosser James.

THE Academy of Medicine of Lyons, at its October meeting, elected this gentleman a corresponding member. As he has spent several years on the Continent, he has probably often visited the second city of France, and will no doubt the more appreciate the honour.

### Meat Preservation.

THE *Moniteur Scientifique* publishes an article from M. Baudet, in which he narrates the result of his experiments on the preservation of meat by phenic acid.

In October last year, he took four wide-mouthed stoppered bottles, and placed in each 250 grms. of raw horse-flesh, slightly moistened with phenicated water in the following proportions:—No. 1, solution at 4-1000; No. 2, solution at 3-1000; No. 3, solution at 2-1000; No. 4, solution at 1-1000. To the contents of every bottle he added a few small pieces of well-burnt charcoal, with the view to absorb any gaseous matter which might be evolved from the meat; after having hermetically closed the bottles, he kept them for thirteen weeks in a room constantly heated at from 15° to 20° C. The state of the meat, on examining it, was as follows:—No. 1. The meat had become somewhat blackish-coloured, but was not spoiled at all. No. 2. Meat very well preserved, colour light rose-red. No. 3. Meat perfectly well kept, with the natural colour of fresh meat. No. 4. Meat has quite well kept; its colour has greatly improved, considering that raw horse-flesh is naturally deep-coloured. A few days after having inspected and noted down, as described, the contents of each bottle, he had taken a portion of the meat of No. 3 bottle, and, without having it washed or drained, fried it, and dressed as a beefsteak; on partaking of it, in company with several other parties, they found the meat excellent, having only acquired a slight taste similar to that of cured ham and bacon, but by no means disagreeable.

### Consumption in Melbourne.

OUR readers are aware that much discussion has taken place respecting phthisis at Melbourne. The *Argus*, that comes to hand just as we go to press, gives the list of the deaths (exclusive of natives) that have taken place in the Melbourne Hospital since August, specifying, as far as is known, the names of the deceased persons, their ages, places of birth, date of arrival in the colony, the names of the vessels in which they arrived, and the causes of death:—

Askew, John, miner, aged thirty-eight, native of Suffolk; arrived in 1855 by the "You Yangs;" died August 7, of *bronchitis*. Ah Tun, hawker, aged thirty-three, native of Canton; arrived in 1855, ship unknown; died August 17, of abscess of liver. Ah Sin, gardener, aged twenty-four, native of Hong Kong; arrived in 1871 by the "Duke of Argyle;" died August 18, of dysentery.

Brown, Harriet, domestic, aged thirty-six, native of London, arrived in 1862 by the "Boanerges;" died August 11, of fracture of the skull. Brennan, Catherine, domestic, aged twenty-seven, native of Liverpool; arrived in 1866 by the "Chariot of Fame;" died August 30, of *phthisis*.

Crowmack, Amelia, domestic, aged twenty-four, native of Manchester; arrived in 1863 by the "Forest Rights;" died August 13, of disease of the liver and kidneys. Cape, Joseph, sawyer, aged forty, native of Durham; ship and date of arrival unknown; died August 13, of dysentery. Cluff, Edwin S., clerk, aged thirty-three, native of London; arrived in 1863, by the "Hastings;" died August 17, of *phthisis*.

Danielson, Chas., seamen, aged eighteen, native of Sweden;

arrived in 1871 by the "Merovian;" died August 18, of *phthisis*.

Grant, Patrick, labourer, aged thirty-nine, native of Ireland; arrived in 1858 by the "Alert;" died August 17, of epilepsy. Greek, Jacob G., miner, aged fifty, native of New York; arrived in 1866 by the "Montreal," of Boston; died August 25, of *pleurism*. Green, John, wheelwright, aged thirty-one, native of Lambeth; arrived in 1854 by the "Pongataboo;" died August 27, of *bronchial pneumonia*.

Hamilton, Patrick, labourer, aged fifty-six, native of Ireland; arrived in 1848 by the "William Stewart;" died August 11, of *pneumonia*.

Jarvis, George, blacksmith, aged fifty-five, native of Northampton; arrived in 1853 by the "Great Britain;" died August 12, of rheumatism. Johnson, Oliver, seaman, aged twenty-five, native of Norway; arrived in 1871 by the "Carnarvonshire;" died August 22, of *phthisis*.

Lynch, William, cook, aged forty-four, native of Barbadoes; arrived in 1860 by the "Meander;" died August 9, of *phthisis*. Lomann, Daniel, super-master Theatre Royal, aged forty-two, native of Germany; arrived in 1866, ship unknown; died August 31, of *phthisis*.

Myers, Chas., stevedore, aged fifty, native of Nova Scotia; arrived in 1846, ship unknown; died August 6, of hydatids in liver. M'Callum, Alexander, labourer, aged twenty-six, native of Scotland; arrived in 1868 by the "Electric;" died August 7, of *phthisis*. Munsen, Peter, labourer, aged forty-seven, native of the Shetland Isles; arrived in 1849 by the "Pemberton;" died August 11, of *phthisis*. Murphy, Wm., aged fourteen, native of Ireland; arrived in 1861 by the "Eastern Empire;" died August 21, of *phthisis*. Myers, Mary, domestic, aged fifty, native of Ireland; arrived in 1855 by the "Sea Park;" died August 25, of cancer. M'Diarmid, Emma, aged thirty, native of Kent; arrived in 1871 by the "Jessie Redman;" died Sept. 1, of *phthisis*.

Noble, William, labourer, aged thirty-seven, native of Scotland; arrived in 1853 by the "Europa;" died August 31, of *phthisis*.

Ryan, Margaret, aged thirty-two, native of Ireland; arrived in 1859 by the "Sam Cairns;" died August 18, of dropsy.

Sheahan, Denis, compositor, aged fifty-three, native of Ireland; arrived in 1852, ship unknown; died August 12, of *phthisis*. Smith, Richard, labourer, aged forty-four, native of London; arrived in 1856 by the "Evening Star;" died August 24, of exhaustion from abscess. Seaton, William, clerk, aged forty-three, native of London; arrived in 1855 by the "Meridian;" died August 25, of *phthisis*. Shakeshaft, Elizabeth, aged fifty-four, native of Hampton; arrived in 1865 by the "Bengal;" died August 28, of exhaustion from gangrene of leg.

Vvyyan, Alfred, compositor, aged thirty-five, native of Cornwall; arrived in 1857 by the "King of Algeria;" died August 8, of *phthisis*.

### Misplaced Sympathy.

THE news of the death of Mr. Robert Bentley, the publisher, was transmitted to America by vigilant newsmongers, and by the Atlantic cable. It was there received as having reference to Professor Bentley. The American Pharmaceutical Association happened to be sitting at the time, and the *Journal of Pharmacy* announces accordingly, that "the intelligence cast a gloom over the members who knew him by reputation or personally, and the sad event was feelingly alluded to by Mr. Henry B. Brady, a personal friend of the deceased."

The *Journal* announces a biographical sketch of the deceased to appear in its next issue.

### Bromide of Potassium.

THIS drug has lately been, as it were, passed in review by a considerable number of practitioners, who have written to some of our contemporaries their experience. We cannot refrain from expressing our surprise that none of these gentlemen have noticed the very important communication on this subject that appeared in the *American Quarterly*, and which—impressed as we were with its

value—we extract from that able journal. Our last volume, therefore, contains the most valuable papers that have appeared on the subject. Still we have no hesitation in taking a few notes from recent letters in our English contemporaries:—

In cases where administered in doses of several scruples daily, says Dr. R. W. Foss, I have seen bromide of potassium produce symptoms of gastric disturbance, and caused a great increase in the quantity of urine passed. In the case of a gentleman, æt. sixty-five years, who had for nineteen months been taking bromide of ammonium, and had epileptic fits every two months, I prescribed half-a-drachm of the bromide nightly, and an interval between the seizures increased from two to four months, followed as the result. Then the dose was increased to forty grains, subsequently to a drachm daily. Great nervous disturbance and gastric irritation followed, and the patient suffered from severe pain in the back of the thighs and the muscles of the legs, much depression of spirits, restlessness, sleeplessness, anorexia, pain above the umbilicus, vomiting, hæmatemesis, malena, and constipation. The pulse was 80, and compressible. The doses were reduced, he having another fit. The bad symptoms disappeared. He now takes the smaller doses with the most satisfactory results, no recurrence of the epileptic seizures for the last fourteen months being displayed.

A lady, fifty-two years of age, consulted Dr. Noble for epileptic attacks occurring bi-weekly. She had suffered from these attacks for many months. No local cause being attributable to them, Dr. Noble prescribed half-drachm doses of bromide of potassium to be taken night and morning, and twenty days afterwards the patient stated she was much relieved. He recommended his patient to continue the bromide of potassium, and a month subsequently she called on him, and although she had no recurrence of the epileptic seizures, she had an unsteadiness of gait and unwonted aspect and deportment. A sad and sunken expression of countenance, a sort of ataxia of the whole muscular system, as if general shaking palsy were imminent. The toxic effects of the bromide had set in. The bromide of potassium was discontinued, and a simple stomachic prescribed, to be taken by her for two or three weeks. She continued to improve, and is now quite well.

Dr. Needham states that for some years he has employed bromide of potassium in the treatment of insanity with most satisfactory results, although in occasional instances temporary depression, loss of weight, and slight furunculoid eruptions followed its use. In two cases, one of mania, and the other of acute melancholia, scruple doses given three times daily produced within a week extreme depression, rapid wasting, impairment of muscular power, dilatation of pupils, hesitancy of speech, great taciturnity, and loss of mental power amounting almost to "paralysis of thought," a condition a strong resemblance to that which accompanies brain-exhaustion, by whatever cause produced. In both these cases suspension of the bromide was quickly followed by the disappearance of its ill effects.

A patient, a young lady, under the care of Dr. Provis, who suffered from epileptic attacks, was treated by bromide of potassium in fifteen-grain doses three times daily. The doses were subsequently increased to forty-five grains, and as the result of the large doses being administered, the patient suffered from depression, bodily weak-

ness, and an eruption resembling ecthyma, impaired memory, drowsiness, and a most offensive and fœtid breath. The symptoms subsided on discontinuing the bromide, but the frequency of her epileptic seizures increased.

#### To Disguise Castor Oil.

THE *Pacific Medical and Surgical Journal* gives the following recipe: Rub up two drops of oil of cinnamon with an ounce of glycerine, and add an ounce of castor oil. Children will take it as a luxury, and ask for more.

JAMES HATTON, Esq., of Hatton, has just presented the Warrington Dispensary with the magnificent donation of £5,000.

WE hear that the ex-Prince Imperial of France is a student in King's College, London.

THE Iron Cross, Second Class, has been conferred upon Dr. Scoffern, of London, "for his courageous presence at the advanced posts of No. 5 Battalion, Prussian army, during the investment of Paris."

THE total class of medical students registered in London up to this day last week, was 1,486, including 470 first year's men.

WE are glad to hear that Mr. Holmes Coote, of St. Bartholomew's Hospital, is now so far recovered as to be able to resume professional work.

DR. KITCHEN, of Middlesboro', records a case in which one-hundred-and-twenty-three plum stones were either removed by himself, or passed naturally through the intestinal canal, of a child of two and a-half years old without any ill result.

A NEW Hospital of splendid dimensions was opened at Dudley on Wednesday, by the Earl and Countess of Dudley. The cost of the building is £30,000, and is a gift by the Earl to the inhabitants of Dudley and district. The endowment consists of £20,000 left by the late Joseph Guest, Esq., of Dudley, for this purpose.

A CORRESPONDENT of the *Chemist and Druggist* calls attention to the ideas prevalent at the Horse Guards with regard to the duty of dispensing medicine. Malta is instanced. At that station there is a garrison of six regiments of the line, a brigade of artillery, two companies of engineers, and a regiment of local artillery, and yet for this large number of troops the government does not provide a single qualified dispenser. The dispensing is done by so-called "compounders,"—men taken from the ranks—who, after a few weeks in the regimental hospital, are paid a little extra, and put to compounding medicines of which they can know nothing. The only qualified man there has the rank of apothecary, and his duty is to be storekeeper, while the most responsible part, "the actual dispensing," is performed by these "compounders." There is a dilemma here for some of the departments. It is evident that a duty which the Privy Council deems of great importance is regarded at the Horse Guards with almost contemptuous indifference.

WE hear that a sewage scheme has been adopted by the Corporation of Birmingham which is to exclude injurious matter from the sewers, and to purify the sewage by filtration upon an area of 900 acres of land. The cost of the scheme is estimated at the enormous sum of £300,000.

THE deaths in London last week were 1,292, being 145 below the average. Fifty-three persons died from small-pox, 34 from measles, 40 from scarlet fever, 6 from diphtheria, 23 from whooping-cough, 35 from different forms of fever, and 46 from diarrhœa.

THE Pharmaceutical Society of England evinces a determination, which we wish we could discern in all Medical Licensing Bodies, not to make money of the sale of qualifications to ignoramuses. Out of two-hundred-and-twenty-two candidates who presented themselves for the first examination last week, eighty-two were rejected.

THE Prussian Government has conferred the iron cross and steel war medal upon Surgeon Manley, Royal Artillery. This medical officer wears the Victoria cross for gallant conduct in the field during the war in New Zealand, and has also been awarded the medal of the Humane Society for saving a sailor from drowning in the Wait-chara River. We congratulate Surgeon Manley on these new marks of distinction conferred upon him, and trust our own Government will grant him the needed permission to accept and wear the insignia of the much coveted order of which he has been enrolled a member.

THE *Army and Navy Gazette* mentions a rumour that Dr. Beaton will soon return to India for a second term of five years as Inspector-General, and adds that this would be a piece of good fortune for the doctor, but a great injustice to the senior officers of his department. The same journal states that Dr. F. W. Innes is spoken of as likely to be promoted to the higher rank. It believes that the retirement regulation cast aside in 1858, or some modification of it, will have eventually to be brought into operation, and wonders how much longer the War Office will defer the reversion to the five years' tenure system for the senior rank.

WUNCU of us who has his favourite panacea for his favourite ailment has appreciated the gravity of his position? Does such a person know that he is a marked man—that his stomach, liver, or kidneys, are under the surveillance of the minions of the land, and that every time he replenishes his bottle, he may be inscribing himself in the *Hue and Cry*?

The discovery of the terrible fact is due to an advertisement in last week's *Pharmaceutical Journal*. £1,250 is offered for the capture of a man named Tully, who has made off with £15,000. We presume he has not a mother's mark, or an anchor tattooed on his arm or any other trade mark on his person, but he has, what is worse, a digestion which requires stimulant tonics, and he has a pet prescription for it. This vulnerable spot in his incognito the pursuing inspector seizes on and forthwith advertises the tonic mixture to the pharmaceutical world. What a moral spectacle? The criminal writhing in the agonies of uncontrolled dyspepsia, and with his infallible preservative at hand forbidden to use it and forced to die. Where is Mr. Boucicault that he does not dramatise the situation?

THE latest cancer cure—the cundurango plant—from which the American newspapers vouched that they had absolutely inspected and fingered innumerable cases of cure, turns out to be an utter humbug. The American government heard so much of it, that they instituted an enquiry in the United States, and sent a quantity of the medicine to our own government, who confided it to the London College of Physicians for trial and report. Dr. Davidson has reported that, so far as the experience of the Middlesex Hospital goes, cundurango is totally inert, and exercises no more influence in arresting the disease than a little flour.

## Literature.

### ST. BARTHOLOMEW'S HOSPITAL REPORTS.\*

THE staff of the great City hospital sends us another volume of Reports, which may fairly rank with its predecessors. It contains, in addition to twenty-one valuable papers, the hospital statistics and the proceedings of the Abernethian Society. Moreover, it is illustrated by five plates. One of these is a fine chromo-lithograph, and three are good specimens of the new process of heliotype. We should be very glad to see all the volumes that are published by our hospitals avail themselves thus freely of art. The cost is no doubt an obstacle, but it is just such works as these which should be brought out in the very best manner. Among the many papers, it is difficult to select. Many, like ourselves, will turn first to Sir James Paget's. This is the story of a private case told in the learned baronet's simple impressive way. It possesses, too, the great merit of brevity. There is not a Bartholomew's man who will not be glad to see it. We therefore cite it in full, knowing that the other contributors will be neither surprised nor dissatisfied to see Sir James taken as a sample of the work:—

"I hope that I may be allowed to offer for the 'Hospital Reports' a case that occurred in private practice, on the ground of its being very rare, and, as I think, a good illustration of certain nervous disorders.

"The patient was a gentleman, twenty-eight years old, with good general health, but emotional, emphatic, and with such a nervous system as, in a woman, might have been called hysterical.

"Eight years ago, because he was very liable to 'catch cold' in the winter, he was advised to use cold shower-baths; and accordingly, for eight successive cold mornings, he stood nearly up to his knees in cold water, and endured the shower. On the eighth morning, when he left the bath, he found his feet numb, cold, 'as white as marble,' in the condition of so-called 'dead-fingers.' From this time onwards he was subject to disturbances in the blood-supply of his feet, of which he had previously had no trace. At first the disturbances were chiefly or, at times, only in the left foot; but, after some years, chiefly or only in the right foot.

"Whenever he walked slowly for so much as half an hour, or quickly for so much as ten minutes, the foot, or feet, became 'dead,' that is cold and numb, and (as he always expressed it) white like marble. They thus changed much more quickly in cold than in warm weather, and often changed in the same manner during cold weather, even when he was at rest. With the deadness he always felt aching, and sometimes severely aching pains at the sides of the foot, and sometimes half-way up the leg.

"This state would continue so long as the patient continued walking; but when he rested, it would in a few minutes change, and the foot, or feet, would become flushed, ruddy, and hot, with over-filling of the veins, and the pain would slowly subside.

\* "St. Bartholomew's Hospital Reports." Vol. VII. London: Longmans, Green, and Co.

"For the remedy of these troubles the patient had been under all manners of treatment at home and abroad. Especially, he had submitted to many uses of baths and electricity; and nothing had done him any good, unless it were some cataplasms made of irritating herbs which, five years after the commencement of his symptoms, seemed for a time to cure him. But the cure, if it may be so-called, lasted only a few weeks. Then the same troubles recurred, except that the right foot in place of the left became the chief or only part in which the disturbances of the circulation were manifested.

"At the time of my seeing him the patient thought himself in his usual state: but it was during warm weather and after he had walked about a quarter of an hour; his foot was not cold or pale, but he said it felt numb and very painful. And while I was watching it, the skin, which was of an ordinary paleness, gradually, and after the manner of blushing, acquired the colour of the deepest blush on a dark complexion. At the same time the foot became hot, and then, slowly, the subcutaneous veins of the foot and leg became tensely full of blood, prominent, and very dark. These appearances slowly passed by, and the foot regained its natural appearance.

"The case seems to deserve record if only for its rarity. I have seen none like it, and can hear of none. But it is more useful for illustration.

"It is a good example of the effects of the shock of cold—a shock affecting for at least eight years the relations of the cerebro-spinal and the vaso-motor nerves of the parts to which the cold was applied. The muscular exercise of a limb commonly leads to the filling of the minute vessels of its skin; in this case it leads to their emptying; and this it seems to do by exciting their muscular contraction, as cold also in this instance does in an extreme degree. Rare as they may be, the examples of injury from the shock of cold are frequent enough to suggest more caution than is commonly used in its employment. Few things hinder recovery from old injuries of joints more than the use of the cold douche in any but very robust persons. And I have known a case in which a patient, who was healthy, except in having a too livid nervous system, became, after being once submitted to a severe cold douche on his back, the subject of all the chief symptoms that commonly follow railway concussions of the spine.

"Another illustration which, I believe, is supplied by this case, is of the probable condition of parts which are the seats of pain or other morbid sensations, in cases of spinal irritation or so-called hysteria. When such parts are out of sight, we are apt to think of them as changed in nothing but their nerve-relations. They are spoken of as only functionally disturbed, this implying that if we could see them they would appear in a perfectly natural state. It is more probable that their vaso-motor, as well as their cerebro-spinal, nervous systems are, as in this case, affected; and that through the vaso-motor influence they are in some cases anæmic, in some hyperæmic, or in both of these conditions at different times.

"More especially, this case seems to illustrate the probable condition of parts which appear healthy in structure, but are morbidly sensible of fatigue. In many cases of spinal irritation, one of the most prominent and constant symptoms is the readiness to be fatigued by muscular or other voluntary exertion. The patient cannot sit up for a few minutes, or walk more than a few yards, without great pain or intense fatigue. The same is observed in many cases of spinal concussion; in which, besides, mental exertion commonly produces very quickly the feeling of great weariness, and of incapacity to continue thinking or working. I can scarcely doubt that the changes of blood supply which this patient showed in his feet are, in other cases, imitated in the blood-vessels of the brain or spinal marrow, or their respective membranes.

"Yet another illustration may be drawn from this case in the fact of the apparently unchanged healthy state of the textures in parts of which the vascular and nervous conditions had been disturbed nearly every day for eight

years. When the circulation in this patient's foot was undisturbed, I could find in it no appearance of disease. No fact could better show that although the vascular and nervous conditions of a part are always disturbed in inflammation, they constitute only a subordinate part in that morbid process. They may be very often and far removed from their normal state, into one like that which they assume in inflammation, and yet no change of structure may ensue in the tissue elements around them."

### ST. GEORGE'S HOSPITAL REPORTS.\*

WE should perhaps have noticed a little earlier this valuable volume which has been some time on our table. We hope, however, now to do it justice by bringing it prominently under the notice of our readers, as one of the very best of the series. It contains a large number of papers well worthy of a place in it, and we trust that it will be found useful to a constantly increasing number of readers. It was our intention first of all, to draw attention to Mr. Venning's paper as particularly interesting, in reference to the agitation on the Contagious Diseases Act. A larger number of readers will, however, be interested in the subject of small-pox, and Dr. Jones's paper gives a very full and clear account of the epidemic that broke out in the hospital. This account is all the better for the cases which have been given, and which we cite in this days MEDICAL PRESS under the head of "Hospital Reports." Next to this, the subject of vaccination deserves and obtains recognition. Dr. Fuller's clinical jottings will be found attractive to many, and indeed each paper will find its admirers. The following is a list of the essays in the volume:—

Jottings from Clinical Practice, by H. W. Fuller, M.D. The Effects of Overwork and Strain on the Heart and Great Blood-vessels, by T. Clifford Allbutt, M.D. On Scarlet Fever, by E. Copeman, M.D. Cases of Accidental Poisoning, by C. Paget Blake, M.D. The Modern Treatment of Syphilis: based on the Evidence adduced before the Committee appointed to inquire into the Pathology and Treatment of the Venereal Disease, by Edgecombe Venning. On Scrofula, by J. Warrington Haward. On Recurrent Insanity, by G. Fielding Blandford, M.D. On Distrain of the Heart, by Reginald Thompson, M.D. Labio-glosso-laryngeal Paralysis, by W. B. Cheadle, M.D. On the Etiology of Pneumonia, by Octavius Sturges, M.D. On Ankylosis, by B. E. Brodhurst. Scarlet Fever as an Epidemic, by A. W. Barclay, M.D. On the Relative Influence of Bread, Honey, and White Sugar upon the Amount of Urea and Sugar excreted in Diabetes, by W. Wadham, M.D. On the Recent Outbreak of Small-pox at St. George's Hospital, by T. Jones, M.D. Results of Recent Vaccination in St. George's Hospital, by R. Wilson. Results of Recent Vaccination in the 1st Regiment of Life Guards, by Edgecombe Venning. Annual Report of Medical Cases, by R. Thompson, M.D. Annual Report of Surgical Cases, by W. Leigh. Ophthalmic Report from December, 1868, to July 1870, by H. Power. Ophthalmic Report from August, 1870, by R. B. Carter. Notes taken in a German Field-Lazareth, by W. Ewart.

### Correspondence.

#### THE UNIVERSITY COLLEGE AND MIDDLESEX HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to an article in the *Lancet* of Oct. 14, headed "University College Hospital," I beg leave to state that students from University College are only admitted to the medical and surgical practice of the Middlesex Hospital on exactly the same terms, with regard both to fees and privileges, as any other occasional students who may enter for

\* "St. George's Hospital Reports." Edited by John W. Ogle, M.D., F.R.C.P., and Timothy Holmes, F.R.C.S. Vol. v. 1870. London: and A. Churchill, New Burlington street.

hospital practice, no preference whatever being given to students from University College over such other occasional students with respect to clinical appointments, for which they are only eligible in event of no general pupil of the Middlesex Hospital offering himself.

The notice in the prospectus of University College, of which mention is made, refers to matters of private arrangement between the authorities and students of University College itself, with which the staff of the Middlesex Hospital are in no way concerned, and of which they had not even been made cognisant.

With regard to the advantages, which the writer of the article intimates, this Hospital would derive from the supposed agreement, by being thereby enabled to fill up its clinical appointments, I may be permitted to state that for these appointments, the large field for practical study afforded by the Middlesex Hospital has never yet failed to secure an ample supply of eligible candidates.

I have the honour to remain your obedient servant,

WM. CAYLEY, M.D.,

Dean of the Middlesex Hospital Medical College.

October, 1871.

[We insert this letter, but think it concerns our contemporary more than the MEDICAL PRESS.—ED.]

#### IDENTITY OF THE FOOT-AND-MOUTH DISEASE AND SCARLATINA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly favour me with the insertion of the following in your valuable space. From a residence of some time in the country, I have had many opportunities of seeing the foot-and-mouth disease, and, having long entertained the idea of its identity with scarlatina, I readily coincide in the opinion with that expressed by Dr. Nicolls in your issue of the 18th inst. I have seen the diagnostic tongue of scarlatina, its edges tipped with red in the cow, labouring under the foot-and-mouth disease, the desquamation going on in the mouth and the foot, large shreds of the mucous membrane peeling off; and I have been told by large stock farmers that the hoofs, in many instances, come entirely away from their dropical legs. I am glad to see the subject taken up now by a member of the Profession, and trust it will be thoroughly ventilated, so that in the end, if successful, it may prove as great a boon to mankind as Jenner's vaccination.

I am, yours truly,

DANIEL HEAGERTY, L.R.C.S.E.

Newcastle-on-Tyne,

October 25th, 1871.

#### SUPPLY OF VACCINE LYMPH IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Variola being at the present time very prevalent in Belfast and neighbourhood, the Medical Profession and authorities are leaving nothing undone by vaccination and otherwise to stop its progress. The great demand that is now being made on the Profession by almost every family to have themselves re-vaccinated, vaccine lymph has in consequence become very scarce, and numerous persons are compelled to have the operation postponed.

Hitherto, the Profession was promptly supplied, on application, with vaccine lymph from London. It now appears, from the enclosed letter, addressed to my friend Dr. Moreland, that this boon is now (at this particular time, too), and in future, to be denied to every practitioner in Ireland; not, as it seems, from any unwillingness on the part of the Inspector of the National Vaccine Establishment, Whitehall, but at the bidding of the Commissioners for administering the laws for relief of the Poor in Ireland.

What object can these Poor-law magnates have in prohibiting a gratuitous supply of vaccine lymph to the Profession in this country? Do they expect that private practitioners, who have been chiefly instrumental in keeping alive public belief in Jenner's great discovery, will thereby be necessitated to purchase from the Dublin Cow-pock Institution, and their having to pay the ordinary price, 2s. 6d., for each supply of vaccine lymph, will ultimately induce them to send their patients to be vaccinated at a public dispensary?

This is a great mistake on their part, and an ungrateful return to the Profession for its gratuitous efforts in stamping out this loathsome disease, and will finally lead a great portion of the people—many already being sceptical—to place no reliance on vaccination as a preventive against variola.

MICHAEL MCGEE, M.D., L.R.C.P.E.

60 York street, Belfast.

"National Vaccine Establishment,

"8 Richmond Terrace, Whitehall,

"Oct. 19, 1871.

"SIR,—With reference to your application for vaccine lymph received this day, I am directed by the Inspector to state to you that from recent correspondence with the Commissioners for administering the laws for relief of the Poor in Ireland, who have been in communication with the Dublin Cow-pock Institution on the subject of supply of vaccine lymph in that part of the United Kingdom, it has been determined that applicants from Ireland to the National Vaccine Establishment should be referred to the Dublin Cow-pock Institution.

"I am, Sir, your obedient servant,

"A. B. FARRE.

"H. MORELAND, Esq., M.D.,

"83 Corporation street, Belfast."

## Inventions.

### XYLONITE.

THIS is a new composition prepared from cotton, oil, camphor, and the hydro-carbons, which will be found useful in surgical cases. From Xylonite a collodion is prepared, applicable to the purposes for which collodion is now so commonly used in surgery. Contained in an air-tight bottle or vessel it is said to keep for any length of time, in any climate, without deteriorating; and to improve by age. Laid upon wounds it adheres, and forms an artificial skin perfectly air-tight; it may be washed with soap and hot water, without being disturbed; but it can be entirely removed, when necessary, by a solution composed of two parts sulphuric ether and one part alcohol.

We have also seen Xylonite in the form of a membrane; from it, also, are to be had proofing fabrics for dressing wounds, hospital sheeting, and all forms of impermeables for surgery.

These dressings and sheetings are almost free from smell, can be cleansed in the ordinary way, with soap and hot-water, or with any disinfecting fluid. They can be dried at a fire, and even ironed at a moderate temperature.

## OBITUARY.

### THE LATE MR. KEMPE.

THIS gentleman who, for sixteen years had been Surgeon to the Devon and Exeter Hospital, died last Wednesday. He had had, on the Sunday previous, a severe accession of his cardiac symptoms, to which he had long been subject. He rallied on Monday, and was able to take a drive on Tuesday. The next morning, however, on entering his room, his servant found him so ill, that he expired before a professional brother could arrive.

He was very much esteemed in the neighbourhood, where he had spent a life of remarkable usefulness, and where he cultivated the art of healing with remarkable zeal. About half a year ago, he retired from the active staff of the hospital, and was elected Consulting Surgeon.

He was also a magistrate, and, indeed, held other offices of honour, by the choice of his neighbours who knew his value. How much he was esteemed by the authorities of the hospital to which he was attached appears from the fact that on the occasion of the first meeting of the Governors of the Devon and Exeter Hospital after his decease, the following resolution was proposed by the Rev. G. H. Shield, seconded by Mr. C. M. Lingwood, and adopted unanimously:—"This Committee avails itself of the earliest opportunity to record its sense of the severe loss sustained by the Devon and Exeter Hospital through the demise of Mr. Arthur Kempe, F.R.C.S., whose skill and devotion to the duties of his profession, combined with a kindness of heart which won the attachment of the sufferers placed under his charge in the wards of this Institution, rendered him for the space of sixteen years one of the best and most esteemed among the distinguished surgeons to whom the Devon and Exeter Hospital in great measure owes its high repute. Sensible of his great public usefulness and private worth, and grateful for his generous gift of a chapel to the Institution, in whose humane work he took so deep an interest, this Committee directs a suitable tablet to be erected within that sacred edifice, bearing an inscription commemorative of his past services and of the high esteem entertained towards him by the Governors of the Devon and Exeter Hospital." It was also resolved that the President, Vice-President, and Senior Physician be a sub-committee to carry out the foregoing resolution.

## Medical News.

**Royal College of Physicians of London.**—At the ordinary quarterly meeting of the College on the 26th ult., the following gentlemen, having passed the required examination, were admitted Members:—John Cook, M.D. Edin., Upper Wimpole street; Thomas R. Glynn, M.B. Lond., Rodney street, Liverpool; Edwin Payne, M.D. St. And., Selhurst road, South Norwood; William Squire, Orchard street, Portman square.

**College of Physicians, Ireland.**—At the recent examinations the following gentlemen obtained the licences in Medicine and Midwifery:—Medicine—Frederick Adolphus Ernest Bernardo, Henry Thompson Cox, Patrick Freebern Gavin, William Robert Hughes, Nicholas Skottowe Smith, Sydney Richard Smyth. Midwifery—Frederick Barnardo, Henry T. Cox, Patrick Freebern Gavin, Wm. Robert Hughes, Richard George O'Flaherty, Nicholas Skottowe Smith, Hatton Smyth, Sydney Richard Smyth.

**Apothecaries' Hall, London.**—At a Court of Examiners, held on the 26th ult., the following gentlemen received the L.S.A. diploma—viz., Messrs. Edward Arthur Burgess, of Bethnal green road; Leonard Cane, of Queen square, Bloomsbury; Thomas Gatsell, of East street, Walworth; Thomas Davies Harries, of Fishguard; Frederick Kimbell March, of Braunston, near Rugby; William Henry Meredith, of Nether-ton; Albert Barnes Rees, of Swansea; and John Wilcocks Watson, of Heigham Hall, Norfolk.

**Society for the Relief of Widows and Orphans of Medical Men.**—At a general meeting of members of the above society held at the society's rooms in London on Friday last, Dr. Burrows in the chair, the secretary read a statement, from which it appeared that the receipts for the past year had been—subscriptions, £593 5s.; making, with payments from other sources, a total of £764 15s. This, together with money invested, made the total resources of the society at the end of the year 1870, £4,908 2s. 6d. After deducting the grants made to widows and orphans, and for expenses, the balance in hand was £1,848 up to the end of 1870. After one or two suggestions as to the expediency of resuming the annual dinner, and of making increased exertions to obtain subscriptions, the accounts were agreed to, and the proceedings terminated with the usual vote of thanks to the chairman.

**The American Pharmaceutical Association.**—The American Pharmaceutical Association which convened at the Polytechnic Institute in the city of St. Louis on the 11th ult., was perhaps the largest and most interesting meeting that has

ever been held. Delegates from the various Colleges of Pharmacy in the United States were largely represented. The convention was in session for four days, the time being devoted to the reading of scientific papers pertaining to the art of pharmacy. There was an exhibition of chemicals, pharmaceutical preparations, apparatus, and in fact everything kept or used by the pharmacist, which was very much admired by every one. The banquet given at the Southern Hotel, by the apothecaries of St. Louis, was a grand affair. It was presided over by Mr. James Richardson, and toasts were read and responded to by pharmacists of the various States.—*Leavenworth Med. Herald and Jour. of Pharmacy.*

**Sassafras Oil.**—The manufacture of sassafras oil has been conducted for the past two years in Richmond, Va., on an extensive scale. The oil manufactured amounts to two per cent. of the stock used, 800 pounds of unrectified oil being made from 40,000 pounds of the root. This quantity is further reduced by rectification and cleansing from sediment and impurity. A gallon of the fine oil weighs 10 pounds and about 40 gallons are produced every week. The root is first cut up fine by a chopping machine, and the raw materials are placed in a large tub, which is closed, and steam is then forced through the mass. The oil is then distilled by the ordinary process. It is largely used for scenting toilet soap, and for flavouring tobacco.—*Med. and Surg. Rep.*

**Medico-Legal Intelligence.**—At Stockton-on-Tees on Friday, a special sitting was held at the County Court, before Mr. Turner and a special jury, to recover damages for £2,000 from David Hope Watson, surgeon, for alleged neglect and unskilful treatment whilst attending the plaintiff, Elizabeth M'Clive Hutchinson, during her accouchment. The case was one referred from the Court of Exchequer of Pleas on the application of the defendant. Mr. Cave appeared for the plaintiff; Mr. Meynell and Mr. Skidmore, instructed by Mr. Draper, for the defendant. In the autumn of 1870 the defendant was engaged in his professional capacity to attend the plaintiff, and it was alleged that, through his mal-treatment, the plaintiff had had to undergo severe suffering and a dangerous operation. Plaintiff's evidence tended to show that the defendant had been too hurried. The plaintiff's mother gave corroborative evidence, and stated that her daughter had suffered greatly. Dr. Parquharson gave evidence to the fact that he was called in, and found the plaintiff greatly suffering. Dr. Trotter deposed that the plaintiff would have died had not an operation been performed. The witnesses for the prosecution were rigorously cross-examined; and Mr. Meynell said that he should adduce evidence to prove that the defendant's proceedings in the matter were perfectly allowable and necessary, and proceeded to call the defendant, who was examined by Mr. Skidmore, and submitted to a long cross-examination. Mrs. Nicholson was then called and examined on behalf of the defendant; and at eight o'clock the court adjourned. On Saturday morning the case was resumed. Drs. Tarleton, Oliver, Dale, Laidler, and Keiller were called to prove the proper mode of treatment. The jury retired for about five minutes, and returned with a verdict for defendant, which was received with applause.

**Royal College of Surgeons, Edinburgh.**—At the annual meeting held on the 18th ult., the following office bearers were elected for the ensuing year:—President, William Walker; Secretary, Dr. James Simson; Treasurer, Dr. John Gairdner; Librarian, Dr. Archibald Inglis; President's Council—Dr. Andrew Wood, Dr. Robert Omond, Dr. James Dunsmuir, Dr. James D. Gillespie, James Spence, Dr. Henry D. Littlejohn; Ex-officio, Dr. John Gairdner.

**Metropolitan Asylums Board.**—The Cholera and Small-pox Questions.—At a meeting of the Metropolitan District Asylums Board on Saturday last, in the Court Room of the Board of Works, Spring gardens—Dr. Brewer, M.P., in the chair—a communication was read from the Westminster guardians asking if, pending the Hampstead Hospital inquiry, small-pox cases could be sent to Homerton, and if not, what course should be pursued; also a resolution from the St. James's Vestry, asking what steps had been taken to provide for a change in the management of the hospital pending the inquiry.

Dr. Shaw's report from the Leavesden Asylum stated that there were 1,636 patients there—738 males and 898 females—of these there were attended with occasional violence 6 males and 6 females, and cases finishing curable 6 males and 6 females.

A report from the Hampstead Hospital Committee showed that small-pox is again on the increase. During the past fortnight 71 fresh cases of small-pox had been received, 7 had died, and 36 had been discharged, leaving 141 under treatment, as against 113 at date of last report. The total number treated up to the present time had been 5,696, of whom 1,073 had died, and 4,482 had been discharged.

The report from Dr. Adams showed that there are 1,600 patients in the Caterham Asylum, viz., 671 males and 929 females; of these 57, viz., 29 males and 26 females, had occasionally shown some instability or excitement; and 24, viz., 6 males and 18 females, are probably curable.

## Cleanings.

### On Xanthelasma Multiplex (Molluscum Lipomatodes), by Rud. Virchow, along with Notes by Dr. Leber.

In the case detailed, yellow tumours existed on the cornea, and darker ones in the popliteal region of the leg. The author confirms the observation of Waldeyer in the former part of the *Archiv*, that in this tumour the colour depends in a considerable degree on a fatty metamorphosis of the cells, though in the tumours in the leg the colour was also in part owing to increase of the pigment of the rete malpighii. At the margins of the tumours he found proliferating connective-tissue cells, and the tumours obviously had their origin from this tissue. Like Waldeyer, he found that though the cells were fatty yet they did not show any necrobiotic tendency. It is not proper to call this a fatty degeneration, therefore, because the cells retain their integrity, it is rather of the nature of a fatty infiltration. Virchow looks on the tumours as essentially of a fibrous nature, but that there is a partial conversion of the connective-tissue into fatty tissue. Just as a fatty tumour sometimes undergoes condensation and partial conversion into a fibrous tumour, so these, though fundamentally fibrous, are partially converted into fatty tumours. Now tumours of a fibrous structure existing in the skin and in considerable numbers, have been designated by the name of molluscum. And Virchow considers that the tumours existing in the leg in this case were cases of simple molluscum, with this tendency to conversion into adipose tissue. And he would prefer that this fact of their structure should be expressed in the name of the group, and so, instead of the name xanthelasma multiplex, would substitute molluscum lipomatodes.—Dr. Joseph Coats, in *Glasgow Medical*, from *Virchow's Archiv*.

### Encephaloid Disease of the Right Superior Maxilla. Resection of the Bone.—Recovery.

WM. A. GORR, M.D., of Veroqua, Vernon Co., Wisconsin, writes as follows in the *American Journal of the Medical Sciences* :—

In the latter part of May, 1869, R. L., aged sixty, of nervous temperament, a farmer by occupation, of impaired health, consulted me in reference to a disease of the right upper alveolar process. He stated that he has experienced an occasional pain of a sharp, lancinating character in that side of the face for nearly twenty-five years, but of such a transitory nature as to have given rise to no uneasiness as to its serious import; also that his general health had always been good until about two years ago, when from some cause or other it began to decline more or less rapidly.

I found, on examination, the entire alveolar process to be one mass of fungoid disease, through which the only remaining teeth, the second molar and canine, protruded. I extracted these teeth for the purpose of ascertaining the condition of the antrum; this was found to have become implicated, and from it a foul, bloody discharge issued. The opening made by the extraction of the canine tooth would have admitted the end of the little finger, being partly occupied by a dark-coloured fungous mass of the consistence of brain, which came away in fragments when broken down by a probe. A probe introduced into the opening met with no obstruction until its extremity impinged against the under surface of the floor of the orbit. The patient was much emaciated, and his strength so much weakened that his gait was tottering and unsteady, his appetite impaired, and his pulse feeble. The skin covering the bone was slightly discoloured for a space of about an inch commencing at the ala

of the nose, and extending transversely that distance; there was tenderness on pressure at that point, and some puffiness of the integument. For the relief of the patient, an operation consisting in the resection of the bone entire or in part, was clearly demanded; but his condition forbade any such procedure at the present time. He was, therefore, put upon a preparatory tonic treatment, with a nutritious diet. The local treatment consisted of astringent washes and injections into the cavity of a solution of carbolic acid, grs. x to an ounce of water.

The patient having improved in health, the operation was performed on the second of July, and was the one advised by Velpeau, his modification of Gensoul's method. I was ably assisted in the operation by Dr. H. A. Chase, of Veroqua, and Dr. Charles Poff, of Readstown, in this county. The patient having been placed under chloroform (this occupied upwards of an hour at the least calculation, on account of the impurity of the article), an incision was made from near the outer angle of the eye to the commissure of the lips; the large flap thus formed was dissected from below upwards and turned back out of the way. The bone being thus exposed, I next proceeded to sever its connections with the other bones of the face. With Liston's cutting pliers, the external orbital process at its junction with the malar bone, the zygomatic arch, and the os unguis, were cut through, and the ascending nasal process with a narrow chisel and mallet. The two incisors of the right side having been extracted, the two maxillæ were separated in front with the metacarpal saw, and also its palatal process as far back as its junction with the palatal process of the palate bone, as well as its transverse connections, which were divided by the chisel and mallet through the mouth. The bone being now seized between the thumb and fingers, was forcibly moved from side to side, and after a little effort raised from its bed. The cavity, having been cleared of any remaining shreds of the tumour, was filled with lint. Very little blood was lost during the operation, not to exceed eight ounces. But a single vessel required the ligature. Before bringing the lips of the wound together, the indurated tissue on the inner surface of the flap where it had been in contact with the tumour, was shaved off. As soon as the anæsthesia had passed off, half of a grain of sulphate of morphia was administered, and the patient placed in bed.

On the fifth day after the operation the sutures were all removed, and the wound was healing by the first intention throughout; the flaps were supported by adhesive straps in case of accident. For a few days after the operation there was slight febrile reaction, lasting for three or four days, after the subsidence of which the patient made a rapid recovery, and about the fourteenth day was walking about his room. He complained of some difficulty in deglutition and in articulation, but no more than is to be expected after this operation; both gradually became less annoying in a much shorter time than I had anticipated. The tumour presented all of the characteristics of true encephaloid disease.

P.S.—Up to date of present writing, November 5, Mr. L. continues in the enjoyment of excellent health. He informed me a day or two ago, that since the operation, it has been better than for a number of years past. The parts have healed kindly and soundly to all appearances. I shall deem it my duty to report the subsequent history of this case, as too short a time has elapsed since this operation to determine its result.

## NOTICES TO CORRESPONDENTS.

•• We are requested by the Editor of the "Irish Medical Directory," to urge those gentlemen who have been dilatory in returning their Circulars, to do so at once. Those who will kindly do so, will, at the same time, save expense to the Editor, and ensure an accurate description of their qualifications and offices.

## Marriages.

ATKINSON—MORLEY.—On the 25th ult., at St. Peter's, Derby, John P. Atkinson, M.D., of Bampton, Oxon, to Mary, second daughter of the late Wm. Morley, Esq., of Briz-Norton, Oxon.  
 BOYD—CARR.—On the 26th ult., at St. Margaret's, Lee, Kent, Robert Boyd, Esq., of Glasgow, to Annie Gertrude, elder daughter of Wm. Carr, Esq., M.D., F.R.C.S.E., of Lee Grove, Blackheath.  
 FREEMAN—CROSBY.—On the 24th ult., at St. Mary's, Lewisham, Kent, J. C. Freeman, to Ellen Sarah, daughter of J. L. Crosby, M.R.C.S., of Carlton, Cambridgeshire.

## Deaths.

KEMPE.—On the 25th ult., Arthur Kempe, F.R.C.S.E., of Exeter.  
 KING.—On the 24th ult., at Walton villa, near Eccleshall, O. King, Esq., F.R.C.S., late of Royal Hill, Greenwich, aged 54.  
 REID.—On the 16th ult., T. Reid, L.R.C.S.Ed., of Slievroe, Co. Monaghan, aged 65.  
 SNOOK.—On the 15th ult., John S. Snook, M.R.C.S.E., of Colyton, Devon.  
 SEARLE.—On the 25th ult., at 4 Magdalen terrace, Exeter, Frank Furlong Searle, M.R.C.S., F.R.G.S., aged 32.

Established 1848.

## PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY LL.D. M.R.C.S., F.L.S., &amp;c., (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &amp;c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

PRACTICES AND PARTNERSHIPS NOW OPEN for negotiation (in addition to those advertised in Dr. Langley's List, (which is sent post free on application).

Y 325. The leading PRACTICE in a TOWN on the South Coast. Receipts during present year, over £800. Average of three previous years, about £750. The connection is very old-established, and the patients of an exceptionally good class, including all the best residents in the District. The house is a good family mansion, with large reception rooms, gardens, stabling, &c. The work is extremely light, occupying usually not more than about four hours a day. No assistant required. About thirty cases of midwifery a year, at good fees. The vendor occupies a good social position in the town, which contains about 16,000 inhabitants. Terms, a year and a half's purchase, part, however, may be left on security, if desired. The Successor must be thoroughly acquainted with his profession, and accustomed to good society.

Y 313. Partnerships in a first-class Country PRACTICE, in a WESTERN COUNTY. The income was formerly £900 a year, but has declined in consequence of the advancing age of the incumbent; who, however, retains the best part of the connection, returning fully £600 a year. The Practice is capable of almost unlimited increase, as the district is populous, and there is no opposition within four miles. Two horses and one carriage are used. Appointments yield £110. A suitable gentleman would be admitted upon easy terms, but must be able to command £500.

Y 312. High-class Non-dispensing PRACTICE with Partnership introduction. The average receipts have been about £1,000 a year, but have increased largely during last year. The patients include the aristocracy of the district. Midwifery fee, £5 5s. to £10 10s. Nearly the whole Practice lies within a mile radius. Visits, 5s. and 7s. 6d. The incumbent holds two government appointments, which yield about £100 a year. The residence is one of the best in the locality, in a charming situation, commanding a view of the sea and parts of the South Coast; being the Vendor's freehold, it can be purchased, or rented, or a smaller house adjoining could be occupied by the partner during the introduction. The successor must be well-qualified and accustomed to good society.

Y 320. In a pleasant and improving TOWN, a very OLD-ESTABLISHED PRACTICE, held by vendor for the last seven years. Average receipts about £760 a year, including easily worked Appointments producing £200 a year. No union. One Horse and carriage sufficient; the patients are chiefly of the upper middle-class. An efficient introduction can be guaranteed; part of the premium may be left on security.

Y 326. PARTNERSHIP with succession in three or five years, in a first-class PRACTICE in Notts. The present income is £800 a year, which can be doubled by the co-operation of a suitable gentleman, who is well up in operative surgery. It is the leading practice in the District, and affords an introduction to the best society. Midwifery fees from three guineas to five. Visits 5s., with mileage extra. A Dispenser is employed, but no other assistant necessary. The partner, if unmarried, could at first reside with the vendor. Terms based on two years' purchase, with concessions as to mode of payment.

## FRAGRANT SOAP.

The celebrated "United Service" Tablet is famed for its delightful fragrance and beneficial effect on skin.

MANUFACTURED BY

J. C. AND J. FIELD, Patentees of the Self-fitting Candles Sold by Chemists, Oil and Italian Warehousemen and others.  
Use no other. See name on each tablet:

**BICHLORIDE OF METHYLENE.**  
THE NEW ANÆSTHETIC.

Superior in its action, and pronounced to be much safer for administration than chloroform, 2s. per oz. COMPOUND ANÆSTHETIC ETHER, for producing Local Anæsthesia.—SPECIAL ADVANTAGES: Lower specific gravity and boiling point than pure Sulphuric Ether, less odour, and quicker action in producing insensibility. In 4-oz., 10-oz., and 20-oz. stoppered bottles, 2s., 4s., and 7s.

STYPTIC COLLOID, for promoting the Healing of Wounds by the first intention, for treating Open or Fetid Wounds, and for arresting Hæmorrhage. In 2-oz. and 4-oz. bottles, with brush, 2s. 6d., and 4s. 6d.; 16-oz., 12s.

OZONIC ETHER, or ETHERIAL PEROXIDE of HYDROGEN, for Diabetes. In 4-oz. bottles, 3s. 6d.; 10-oz., 7s.; 20-oz., 12s.

PEROXIDE OF HYDROGEN. In 4-oz. bottles, 2s.; 8-oz., 3s. 6d.; 16-oz., 6s.

CHARCOAL CAPSULES, containing pure Vegetable Ivory Charcoal. In boxes, 2s. 6d. each

**J. ROBBINS & Co**  
OXFORD ST. 372

## PRIVATE RETREAT

FOR

THE UPPER AND MIDDLE CLASSES

OF BOTH SEXES, MENTALLY AFFLICTED,

TUE BROOK VILLA,

NEAR LIVERPOOL.

Further information may be obtained on application to Dr. H. OWEN. Vide page 1075, "Medical Directory," 1869.

## THE HANDIEST SHOP IN LONDON.—50 per Cent.

Saved.—PORTMANTEAUS, 5s. to 50s.; Hat Cases, Carpet and Leather Bags, Trunks, Boxes, Silk Umbrellas, 2s. 6d. to 10s.; Revolvers, Cricket Bats, Fishing Rods, Guns, Gun Cases, Foot Balls, Croquet; Dumb Bells, 2d. per lb.; Ivory-handled Knives, Baths, Ferambulators, 14s., warranted; Weights and Scales, Carpenters' and Gardening Tools, Tents, Flower Stands, Whips, Stable Brushes, Parrot and Bird Cages, Opera Glasses; Cash Boxes, 2s.; Account Books, Deed Boxes, 6s.; Iron Safes, 48s.—GOFF, 15 and 16 New street, Covent Garden.

## COKESTOWN HOUSE, INSTITUTED FOR

## THE MEDICAL TREATMENT OF THE INSANE OF BOTH SEXES.

This highly respectable Mansion in no respect resembles, either internally or externally, what is usually known as an Asylum.

The Demesne, Conservatories, Graperies, and Grounds are unusually extensive, and in good condition.

There are Billiard Tables for both sexes, with indoor and outdoor amusements, including Vehicles.

Cokestown House is within three miles of Carrick-on-Suir Station, with a like distance from Fiddown, both on the Waterford and Limerick Lines, and in connection with the G. S. & W. and Kilkenny Lines.

For terms, and Form of Admission, apply to the Resident Physician.

JOHN PEPPARD, M.D., &c.  
Cokestown House, Piltown, co. Kilkenny.

## THE WESTMORELAND LOCK HOSPITAL

FOR THE TREATMENT OF VENEREAL DISEASE,  
TOWNSEND STREET.

## SURGEONS TO THE HOSPITAL.

Benjamin M'Dowell, M.B., F.R.C.S., L.K.Q.C.P., L.R.C.S.I., Professor of Materia Medica in the Ledwich School of Medicine, &c., Surgeon to Mercer's Hospital.

John Morgan, A.M., T.C.D., L. and F.R.C.S.I., Professor of Practical Anatomy (Surgical and Descriptive) Royal College of Surgeons, School of Surgery, and Surgeon to Mercer's Hospital.

THE HOSPITAL contains 150 Beds; 674 patients were admitted during the past year suffering from every variety of Venereal Affection, thus affording ample opportunity of studying the disease in all its forms.

The wards are visited daily between twelve and two o'clock, so as not to interfere with attendance at general hospital practice.

Two Clinical Lectures will be delivered each week, commencing the first Monday in November.

Fee for Hospital attendance, including Clinical Lectures:—For Winter Session, six months, £1 4s.; for the Summer Session, three months, £2 2s.

For further particulars apply to Dr. M'DOWELL, 20 York street; or Mr. MORGAN, 23 Stephen's green North, or at the Hospital.

**METROPOLITAN DISPENSARY AND CHARITY TABLE FUND, 9 FORE STREET, CRIPPLEGATE.**—The Office of Surgeon to this Charity is now vacant by the resignation of Sidney Chater, Esq. Candidates must be Fellows or Members of the Royal College of Surgeons of England, not practising Pharmacy. Testimonials will be received at the Dispensary, until 4 o'clock on Tuesday evening, the 7th November, when Candidates must attend the Committee with their diplomas, and the Committee will fix the day of Election. All further particulars relating to the Institution, and the duties of the Office, may be obtained upon application to Dr. Southwood, the Resident Medical Officer, or to the Secretary.  
By Order of the Committee,  
FREDERICK STILES, Secretary.

6 Fore street, Oct. 1871.

## LECTURES ON EXPERIMENTAL &amp; PRACTICAL MEDICINE.

By BENJAMIN W. RICHARDSON, M.D., F.R.S.

WINTER SESSION, 1871-72.

The first Lecture of the Eighth Course on Experimental and Practical Medicine will be delivered at 12 Hinde street, W., on the last day of the present month, Tuesday, October 31st. The Course will be continued on the last Tuesday of every succeeding month until March.

The subjects of Lecture will be divided into two parts: one part will be essentially practical, treating of the newest developments of Medical Science in their applications to the daily exercise of Medical Art; the other part will be experimental, treating of the way that lies open for new discoveries, or for the perfection of discoveries in the science and in the art of Medicine.

At each Lecture, as the opportunity may offer, specimens of recent inventions, new therapeutical substances, or other useful practical agencies for the treatment and cure of disease, will be demonstrated.

The Course is specially intended for Members of the Profession engaged in actual practice; but it may be attended by Students of Medicine who are advanced in their curriculum of study.

The present Series will commence with a Lecture on "The Science and Art of Embalming the Dead."

The Lecture Hour is from 5 p.m. to 6 p.m.

Entrance fee, £1 is.

Entrance-tickets can be obtained during the half-hour preceding the Lectures, or on application by letter address to Mr. Toole, 12 Hinde street, W.

## ROTUNDO LYING-IN HOSPITAL, DUBLIN.

Consulting Physician—Alfred Hudson, M.D., F.K.Q.C.P.I.

Consulting Surgeon—Robert Adams, M.D., F.R.C.S.I.

Master—George Johnston, M.D., F.K. Q.C.P., &c.

Assistant Physicians—Alex. Taylor, L.K.Q.C.P., &c. J. J. Cranny, L.K.Q.C.P., &c.

Secretary—J. G. Strickland, Esq.

This Hospital, the largest Chartered Clinical School of Midwifery in the British Dominions, contains one hundred and thirty beds, twenty-five of which are appropriated to the Diseases of Females.

The Lectures are recognised by the Royal College of Surgeons in Ireland, London, and Edinburgh; the King and Queen's College of Physicians; the Apothecaries' Hall of Dublin and London; the Army and Navy Medical Boards; and all the other Licensing Bodies.

The Diploma from this Hospital is recognised by the Poor-law Commissioners as a qualification in Midwifery for all Hospitals and Dispensaries under their control in Ireland.

The Intern Pupils, of whom there is only a limited number, have each a separate bed-room, with the use of a sitting room.

Two courses of Lectures are given yearly; the first commencing early in November, the second early in May.

Applications to be made to the Master or Secretary, at the Hospital, Rutland Square.

## CITY OF DUBLIN HOSPITAL.

Physicians.

J. H. BENSON, M.B., T.C.D., L.K.Q.C.P., L.R.C.S.I.

J. M. PURSER, M.D., L.R.C.S.I., L.K.Q.C.P.

Surgeons.

WILLIAM HARRAVE, M.D., F.R.C.S., Professor of Surgery R.C.S.

JOLLIFFE TUFNELL, F.R.C.S., Ex-Regius Professor of Military Surgery, and Examiner in Surgery, R.C.S.

H. G. CROLY, F.R.C.S., L.K.Q.C.P.I., Senior Demonstrator of Anatomy, R.C.S.

WILLIAM THORNLEY STOKER, M.D., L.R.C.S.I., Demonstrator of Anatomy R.C.S.

Ophthalmic Surgeon.

LOTFIE STONEY, M.D., F.R.C.S.

Consulting Physicians.

Professor APOJN, and CHARLES BENSON, M.D.

Consulting Obstetrical Physician.

T. E. BEATTY, F.K.Q.C.P.

Consulting Ophthalmic Surgeon.

ARTHUR JACOB, M.D. (Hon.), T.C.D., F.R.C.S.

The Clinical Lectures will be delivered on three days in the week by the Physicians and Surgeons, and Special Courses on Diseases of the Eye will be given by Dr. STONEY.

The Certificates of attendance are received as qualification by all the Colleges, Halls, and Boards.

For further particulars apply to Dr. STOKER, 43 Harcourt street, between 3 and 4 o'clock.

### DUALITY OF THE CHANCRE.

By CHARLES R. DRYSDALE, M.D., M.R.C.P.L., F.R.C.S.E.,  
Physician to the Metropolitan Free Hospital, &c.

IN a former essay (MEDICAL PRESS AND CIRCULAR, Oct. 5th, 1871), the writer of this paper gave in his adhesion to the proposition that syphilis, or that disease, which is the cause of so many skin eruptions and so many internal lesions, was new to Europe until the year 1493, when it was brought to Europe by Columbus, in March of that fatal year. If, then, there were any clear proof that other venereal diseases existed in Europe previous to that date, it would go far to prove that they had nothing whatever to do with syphilis. Turning to ancient writers on medicine, then, we find Celsus (lib. vi., chap. xviii.) speak thus, "Therefore, if the penis be swollen from inflammation, the prepuce cannot be drawn back, this is phymosis, or forward paraphymosis. If the foreskin cannot be reduced, the superior surface must be divided gently with a scalpel. . . . Ulcers will be found behind the posterior parts of the prepuce, or on the gland, these ulcers will be either clean or dry, or moist and purulent. . . . Not unfrequently the penis has been destroyed to such a degree beneath the prepuce by these ulcers, that the gland has fallen off. There is also a species of ulcer found there sometimes, which the Greeks call phagedæna. Here no time must be lost; but the same caustic remedies must be immediately applied, and if they avail not, the part must be burnt by the actual cautery."

Many persons may be inclined to look on this passage as a clear proof that soft chancre existed in the days of Celsus; but there is an indefiniteness about the definition of such chancres, which will, we hope, become more apparent as we go on. In Paris, the majority of writers

on syphilis are now completely convinced that the soft sore has always existed since the history of medicine, and that the initial lesion of syphilis has only been seen in recent ages. In England, Mr. Henry Lee and Mr. Berkeley Hill may be said to be the chief champions of this opinion; and, in the United States, Dr. Bumstead has made this opinion to be widely shared by some of the ablest of the young men of that country. In the works of Hippocrates (Coxe's "Hippo. and Galen") we find the passage, "Great fluxes upon the private parts, with ulcerations, tubercles inwardly and outwardly were frequent. Also swellings in the groin, inflammation of the eyes that were humid, and of long duration and painful." Dr. Jepson (*New York Medical Journal*, September, 1871), says: that Renouard, in his "History of Medicine," observes that "Hippocrates, Galen, Celsus, and the Arabian physicians make mention of pustules, ulcers, phlegmons, excrescences, and crusts, located on the genitals, and neighbouring structures." It is strange that neither Horace, Ovid, nor Juvenal, whose works the writer has quite recently consulted, ever seem to speak of such ulcerations, and they never even mention gonorrhœa. During the Middle Ages, one writer, called W. de Salicet, writing in 1290, A.D., speaks of bubos occurring after connexion with a prostitute. Dr. Vidal, of Paris, quotes Lanfranc, a pupil of Salicetus, who says that, "ulcers of the penis proceed either from hot pustules, or from commerce with a woman who has been previously afflicted in the same way. . . . Often an abscess comes in the inguinal region, on account of an ulcer on the penis." Bernardus Gordon, professor of medicine in Montpellier University, writes too, in 1300 that "Diseases of the penis are numerous, following lying with a woman whose womb is unclean, full of putrid sanies, &c." (*See Dr. Jepson's article, loco citato.*)

The writer has already remarked that no such account of true syphilis is to be found in the writings of any writer before the year 1493, which is not the case in other diseases, such as cholera, plague, or small-pox. The history of medicine gives us the epoch of the appearance of such scourges. We never hear too among the ancients of hereditary syphilis; and Littré truly says,

that none of the Greek or Latin writers speak of such phenomena as exostosis, iritis, or hereditary eruptions, &c.

It appears that for a long time there was no clear distinction made between the ulcers which gave rise to syphilis, and the class of sores which had always been known to physicians, until about the middle of the 16th century, when Nicolas Massa (1532) remarked that the ulcer of the genitals, which was accompanied by a bubo, was not often followed by any other symptoms. Fallopius (1555) also seems to have made a distinction between the sores; and N. De Blegny (1673) speaks of *hardness* of the ulcer being a sign that secondary eruptions would ensue. Coming down, however, to Hunter's days, we find that he, writing in 1784, teaches that the various forms of gonorrhœa and syphilis depend on the same poison. Vigo had truly, long before, spoken of induration. "Quoties videtis sanatam cariem, et quod remanet calli circa cicatricem," he says, in one of his passages, "then you may be sure that the morbus Gallicus exists." Hunter spoke often of induration, and, after this great writer, Abernethy observes that many ulcers were not followed by constitutional effects. He writes in 1814, that he has never seen phagedæna followed by secondary eruptions. Although this is not a true observation of nature, it shows that Abernethy had noticed that *some* ulcers were more likely than others to be followed by the disease. Richard Carmichael, of Dublin, in 1814, said that the syphilitic poison always produced a chancre of slow progress. He believed, however, that there were several other poisons (venereal), and in this point was rather confused in his account of syphilis. Ricord commenced a series of investigations, which he published in 1838, which led him to say that there was only one virus, although he recognised that indurated sores were the ones which were followed by constitutional symptoms, and for a long time he led the school of *unicity* in Europe. At the same time, he remarks in his "Lettres la Syphilis," 1851, that "There are chancres, and perhaps they are the majority, which do not infect the constitution." It was reserved for Dr. Bassereau, one of Ricord's own pupils, to assert categorically that syphilitic sores have nothing to do with other venereal ulcers, in the year 1852. His discovery in the eyes of the writer of these lines was a most fortunate one in more ways than one. Among other advantages, it immensely diminished the number of persons who were destined to take large quantities of that very dangerous article of the Pharmacopœia, mercury. The arguments used by Bassereau are certainly very convincing, although there are one or two difficult points still remaining to be settled in the theory of dualism. Bassereau was in the habit, whenever he could do so, of confronting the affected patient and the person by whom he or she had been infected. He found that persons with syphilis had always been infected by some person, whose sore had been followed by constitutional symptoms; and that persons with suppurating soft sores, which led to nothing, had always received these from persons with sores of like nature, and which had not infected the constitution. Drs. Clerc, Diday, Rollet, and others soon followed in Bassereau's track and gave cases to prove his thesis. The writer of these lines has himself very frequently confronted patients affected with syphilis (especially married women) with those who infected them, and has been always able to verify Dr. Bassereau's conclusions. Whilst he writes these lines, two married ladies are under observation, with syphilis obtained from their husbands. Both of the husbands have had non-suppurating sores, followed by scaly eruptions, in their history. In the same way, numerous cases of soft sore have been seen by him to have been derived from women suffering from such sores, or in wives derived from husbands with such lesions, which were not followed by syphilis. In many cases in clinical experience, the writer has seen and heard of syphilis transmitting itself by means of indurated and non-suppurating sores on the lips; and whenever secondary symptoms, or the matter from hard sores have been experimentally in-

oculated on virgin subjects, the result has uniformly been a non-suppurating sore, with none of the characters of soft chancres. The experiments of Waller of Prague, Vidal, Rinecker, Wallace, and Anzias Turenne are quite conclusive in this matter. Anzias, too, found that soft sores could be transmitted to the lower animals, whilst syphilis could not.

The initial sore of syphilis is rarely re-inoculable on the patient himself; and the soft sore, it has been noticed, is very rarely indeed ever seen on any part of the head or face, whilst the non-suppurating sore is not at all unfrequently seen on the lips, although it is now well known, that the soft sore may easily be artificially inoculated on the face. Among other authors who have now adopted the theory of duality of the two poisons is Sir H. Thompson, who, in 1858, read a paper before the Harveian Society of London, in which he said, that in five cases out of six, we may diagnose between those sores which will be followed by syphilis, and those which are mere suppurating, or "soft" sores. The writer of these lines quite endorses Thompson's remarks. It is only occasionally difficult to make out whether a sore is the initial lesion of syphilis or not *in the male*. Incubation almost always is rather long, in cases when the poison of syphilis is inoculated in a virgin subject, Hunter, Lawrence, Rollet, (1865) Bumstead, Fournier, and a host of other writers, among whom Dr. R. McDonnell is one of the most reliable, may be mentioned, to prove this point. Baerensprung says: that four weeks is the *average* period of incubation in syphilitic infections, before the "initial lesion" appears at the spot where inoculation was performed (Die Her. Syph). In some cases, which the writer has seen clinically, where syphilis has been inoculated by the lips, the incubation period has lasted several weeks. Now, in the immense number of cases of inoculation of "soft sores," there is hardly any real incubation; and the writer has in very numerous instances found that in a day or two after inoculation, the pustule begins to form. It is true that the incubation period in syphilis has been noticed to be sometimes only ten days; but, as in all similar animal poisons, much depends on circumstances, with regard to the incubation period. The infecting sore commences as a papule or abrasion, and this is soon surrounded by induration more or less marked; whilst suppuration is uncommon and not at all essential in such sores. In the *soft sore*, however, a *pustule* forms and suppuration always takes place. The first sore is usually rough; the second often multiple; the first sore is sometimes elevated above the surface, the second is always excavated. The lymphatic glands are indurated in the groins in the "hard" sore; they do not suppurate in such cases; whilst, in "soft" sore, they often do. Fournier (*Amer. Journ. of Syphil. and Derma.*, Oct., 1870.) says that indurated sores are by no means rare in women. Hardness of chancres may be entirely wanting in the initial lesion of syphilis, and the point is one of the objections made by many to the doctrines of Bassereau. It is doubtless one of the arguments which slightly weakens the force of his cogent evidence; but in the writer's opinion, the arguments for duality are too strong to be thus overthrown. It is true, that M. Clerc, in 1854, has made the conjecture, that soft sores are merely modifications of the syphilitic sore; and that they are the result of inoculations made with syphilitic sores upon persons suffering from syphilis. Mr. Henry Lee, however, in 1856 found that it was most difficult to make the secretion from a syphilitic sore taken upon a person suffering from constitutional syphilis, unless the sore were previously irritated, and made to secrete pus by some irritating substance, such as savine ointment. And this practice has been followed by Professor Boeck, Dr. Bidentkap, and others, when they desire to have pus where withal to inoculate, in their process called "syphilitisation." Bidentkap and Kœbner (Boeck's "Récherch sur la Syphilis") seem to prove, that when a hard sore is irritated, its secretion can be inoculated on a syphilitic patient with

the result that, within forty-eight hours, a pustule forms, which can be propagated in a continuous series, just as soft chancres can. Bock, therefore, holds that soft chancre is merely one of the forms of true chancre, when the inflammation runs so high, that the constitution (from plugging of the veins) does not become infected. This is the most difficult point for dualists to answer. They have therefore mostly either denied the facts produced by Bock, Bidentkap and Köbner flatly (as some of the Parisians do) or have asserted, either that the lancets used (Berkeley Hill) were probably soiled by pus from soft sores, or (Baerensprung) that ordinary pus will often produce such sores in syphilitic patients, (H. Lee) provided it comes from surfaces that have been irritated. The writer of these lines has witnessed some inoculations made by means of pus sent from Christiania to the London Lock Hospital by Dr. Bidentkap; and is not able to assert that ordinary pus would have produced the soft sores which resulted. Nor does he think that impurity of the lancet used will account for the result. It has not as yet been shown, however, that such soft sores inoculated on syphilitic patients would produce their like on virgin subjects. But, of course, this point should be cleared up by some future observers, although we don't clearly see how this is to be done.

Dr. Jepson is such an enthusiastic follower of the doctrines of Bassereau and of his respected professor, Dr. Bumstead, that he sees less difficulty than the writer of this paper does in this matter. "Granting (he says), (*N. York M. J.*) that our evidence on this point is insufficient; granting even that this soft chancre on the person of a syphilitic patient will produce a soft chancre, unattended by constitutional symptoms, when transferred to an innocent person, yet we cannot do other than accept the duality doctrine; for, if the effect of the chancre and the chancreoid on the system be ever different, the one local, the other systemic, no interchange of species ever occurring, what does it matter clinically, if the chancreoid is a derivative of syphilis?"

In the opinion of Dr. R. McDonnell, there is some connexion between the two sores. He argues that, just as varicella is somehow connected with variola, so is the soft sore with syphilis. As to the experiments made by Mr. Morgan, of Dublin, they have not been long enough before the profession, to be judged of by sufficient experimentation for the writer to dare to pronounce upon the point, whether the leucorrhœa of women affected with syphilis may not, in some instances, produce soft sores on the patients themselves. The most important of all points is this, in the writer's opinion, that all persons who have syphilitic eruptions have been infected, in his experience, by persons suffering from such like eruptions, whether from adults or infants, and there will always remain a little doubt about the matter of the duality of the chancres, so long as the definition of the soft sore is so misty and so vague. Dr. R. McDonnell has informed the writer, that he has seen a sore quite like a soft chancre produced by inoculation from pus from an abscess; and those who were present at a recent debate on Vaccino-syphilis, at the Royal London Medical and Chirurgical Society (1870) will remember, how many good observers acknowledge how difficult it was to make the diagnosis of syphilitic sores, in some instances. Before finishing this short essay, on a most curious and interesting subject, the writer may say, that it is probable that, ere long, the difficulties which he has pointed out will disappear. The silly mysteries which have beset the path of enquirers into any department of medicine connected with the phenomena of generation are rapidly and for ever disappearing; and the best minds in the medical profession are now finding it essential to study nature in all its naked and profound simplicity. Syphilis is too formidable a plague to be put up with by really civilised men, and the sooner we understand its nature, and set ourselves to get rid of it, the better for the race to which we belong.

## CASE OF HYDATID TUMOUR OF THE ABDOMEN.

By DUNCAN R. McNAB, M.R.C.S.E., and TREVOR FOWLER, L.K.Q.C.P., L.R.C.S., &c.

WILLIAM SKINGBY, a farmer, æt. thirty-one years, consulted us on May 23rd, 1871, on account of a pain in the left hypochondriac region. He had previously led a regular life, and had enjoyed good health. Deriving no benefit from our treatment, and, on the contrary, having become much worse, he desired on the 16th of June to be seen at his own home. He had now taken to his bed, and was suffering from a severe pain in the left side, and a frequent desire to pass water, of which he was making a large quantity. Upon examining the abdomen we found an enlargement occupying the pubic region, extending upwards almost to the umbilicus, and bulging on either side into the iliac fossæ. It was firm and elastic, and gave the idea of compressed fluid. Above the left groin was a separate hard swelling about the size of a hen's egg. Both enlargements increased slowly from this time, being accompanied with increasing pain and restlessness. That above the left groin subsequently became softer, and ultimately appeared to blend into the larger mass. Upon the 11th of August Mr. Brickwell, of Sawbridgeworth, met us in consultation. The patient was now suffering from severe pain, sickness, restlessness, and general constitutional disturbance. His circumference was thirty-three inches, and he had visible abdominal pulsation, which was found, however, by change of posture, to be transmitted from the aorta. Supposing the case to be one of hydatid tumour, we introduced an exploring trochar and canula through the linea alba midway between the umbilicus and pubis, and thus drew off about 2 oz. of a clear limpid fluid, which was submitted to the microscope without giving any definite information. Subsequently, on the 18th of August, we introduced a larger trochar and canula in the same situation, and drew off about three pints of a purulent fluid, together with some three or four hundred hydatids, varying in size from a pea to a walnut, some transparent and some opaque. Great relief followed. The canula was secured, and allowed to remain *in situ* for five days, when, having almost slipped out, it was removed. No hydatids or fluid passed after the second day. From this time the swelling again steadily increased till the 15th of September, when the symptoms had become so urgent that we determined to repeat the operation; accordingly, we again introduced the trochar and canula, this time through the linea semilunaris of the right side (that part being the most prominent), and again drew off a large chamberful of purulent fluid and numerous hydatids. Much patience was required in the operation, the canula being frequently obstructed by the larger hydatids, of which many could only be extricated by diligent manipulation with a hooked probe. The canula being secured, was allowed to remain for eight days, during which time large quantities of hydatids were removed daily. A great improvement in the general health was the immediate result of this operation, but a certain amount of pain and discomfort continued, and several hard nodules were still to be felt over the abdomen. On the 1st of October, and for several days subsequently, he passed hydatids and pus *per anum*, which gave temporary relief. Later on his urine contained blood and pus. He is now in a somewhat stationary condition, but there are reasons to fear that a fresh accumulation of hydatids is taking place. Numerous important details have been purposely omitted in this account of the case, but we shall be pleased to reply to any questions from any of our professional brethren, and shall be glad of any suggestions as to future treatment.

### GYMNASIUMS AND GYMNASTICS, ON THE NECESSITY OF THEIR ORGANISATION.

BY E. DALLY.

(Translated from the *Gazette Hebdomadaire* by Mons. B. BERTRAND.)

LET us consider how to organise the practice of gymnastics so as to derive from it all useful effects, and let us at once say what a gymnasium ought to be.

Every airy room, covered, and having a solid floor on two-thirds of its surface can serve as a gymnasium, and will do—at least under the management of an able man—for the practice of gymnastics, without mechanical appliances, can produce most of its useful results, and we must not lose sight of the fact that the movements of the body are more beneficial to it through their continuance than through their intensity. This room must be at least ten or eleven feet high, and the surface must be in proportion to the number of pupils—a square of six and a half feet is required for each pupil as a minimum. According to their usefulness or simplicity we shall here mention as instruments those which are most required: sticks (wooden) one yard and a half long, or, better still, iron bars with rounded weights at their extremities, short (dumb-bells) from eight to ten pounds and upwards, or dumb-bells long, light; or bars of equal weight, suspension bars of pliant ash follow them; then ladders both made of wood and rope, rings, horizontal bars, a porch, sliding poles, clubs, &c., &c. But I repeat again, most of these instruments, however useful, can be dispensed with. Not so with the moveable douche. Whenever one can have water with a pressure of thirteen to twenty-six feet, one must make a reservoir and a conduit; after the exercises a cold douche of one minute produces the most beneficial results, and it is to be regretted that the schools of instruction are all deprived of it, notwithstanding M. Louis Fleury's exertions who has tried during a period of twenty years to introduce this reformation which has been realised in England and Belgium. I refer on this subject to some pages in the *Traité d'Hydrothérapie*, which happily are supported by citations from Pouquet, Van Eschen, and Esquiro. The last author says: Statistics show that the local population of Great Britain degenerates in those towns and villages where gymnastics are more or less neglected, whereas, it develops itself in every place where the manly sports are pursued.

"The system of education has noted these results. In all the large English Schools, such as Eton, Westminster, Harrow, Rugby, one tries to establish an equilibrium between mental and bodily exercises. Even a new system has been introduced in some public schools. The pupils study one half of the day while the rest of the day is put aside for sports and gymnastics.

"Now, looking at the condition of education in Great Britain, we learn that pupils who only spend a few hours in school daily are more intelligent and make more rapid progress than those who all day long sit over their books. The English have reckoned that the powers produced by this system equal for the work a fifth of the British population." (*Revue des Mondes*, May 1, 1862). Thus showing the insufficiency of gymnastic exercise with a great number of subjects the learned observer adds: "we want some agent of general easy application for strengthening every constitution, but especially those who are weak and anæmic, one which can be applied regularly, which incurs neither danger nor inconvenience, and of which the efficacy is indisputable.

"This agent is cold water administered so as to obtain from it stimulating effects only; that is the cold water douche complete and of short duration. Under the in-

fluence of this daily ablution we soon see the skin become reanimated, coloured by the remarkable rising of the capillary circulation. Bright and red blood comes to vivify that vast surface where such important phenomena of vegetative life are effected. Functional activity of the cutaneous covering and the equability of the circulation induce as inevitable consequences a more complete assimilation, a better nutrition; consequently, an easier digestion and a more decided appetite. It requires a fortnight to see this metamorphosis brought about, especially in pale subjects, otherwise tolerably healthy, but in whom the skin deprived of proper stimulants is found in a state of constant inactivity.

"If we consider that the results enumerated will be repeated every day during eight or ten years that the primary and secondary instruction lasts we are struck by the extent of the final result. . . . I am convinced by the invincible logic of facts that the introduction of daily ablutions of cold water in educational establishments will effectually lead towards an entire transformation of public health. Here is the remedy for the fearful scrofula, for rachitis, bronchitis, for consumption; here are the prophylactic means for opposing the ravages of epidemics. You can increase the strength, the vital resistance, while medicine becomes converted to the doctrine of reason. Later when medicine and hygiene go hand in hand we shall have realised what ought to be considered as the end of the art "si vis sanitatem, para morbum."

This excellent page gives us hope that M. Esquiro, being able to do so now, has realised in the Department des Bouches du Rhone the system which he has so clearly demonstrated.

It is more than necessary that such a useful reformation should be put into practice and not exist longer alone in articles and books. Let us go back now to the elementary gymnastics which we suppose to be practised with the appliance of the douche. A costume is very useful. It is to be of cotton or linen, tolerably wide, without buttons, the trousers are to be fastened at the end of the leg so that they cannot move upwards and whirl about. The belt—viz., the gymnastic belt, must be replaced by a linen *écharpe*. I do not understand why M. Triat and his pupils attach such great importance to the *maillot*? in the principal gymnasiums of Paris. This costume is expensive and very uncomfortable. Such are the principles of a gymnasium. And now other questions arise: what are the necessary exercises, how long and how often are the lessons to be? and at last how to get the means to open a sufficient number of gymnasiums and to provide a large quantity of teachers who are clever enough, and who are arduous enough to apply and to introduce gymnastics everywhere where they ought to be.

It is understood that we here cannot enter into all the details upon which the report of M. Hillairet treats with true talent and a perfect knowledge of the subject. But, according to our opinion, he does not give time enough in the *Lycées* to physical education. Four lessons in gymnastics of half an hour each, this is two hours per week, will not signify much. You will not derive from gymnastics considerable results, if you do not devote to it at least one hour each day. As regards the time which you lose in too long studies or in mere play, one hour each day is very little, three hours every week will be sufficient to young people who study for a profession.\*

It is evident that gymnastic marches, quick excursions, ascensions of mountains, of which M. Paz rightly boasts, and which are much in use in Austria and Switzerland must remain out of question—also equestrian, fencing, exercises with the gun, or manual labours of fortification which should be taken with the gymnastics of the higher classes and adults.

\* In my opinion, founded on long experience, one or two hours a week would suffice, provided the pupils had been properly trained. But for this it is necessary that the practice of gymnastics be commenced at an early age. The best results are to be seen in those who do not delay gymnastic exercise later than the seventh year.—TRANSLATOR.

It is not only now that one has observed that bodily exercise, taken with wise consideration, favours particularly the development of the intellect; Plato, Montaigne, Rousseau, and most of the pedagogues have pronounced their views on this subject which are too well known to repeat them here.

It behoves the medical man to experimentally realise this truth, and, as soon as the pupil shall have practised personally he will become an indefatigable propagator. Now, it would be best in every respect to make it a rule that every student in medicine should practise gymnastics for one year before his fourth study-year—this would prove very much in favour of the propagation of physical education. Most probable it is that it also would have most salutary effect on the morals of our students; young men like to associate together, and if spending time in coffeehouses has so much developed it is because during the Empire no free meetings were allowed to be held. Bodily exercise taken by many at the same time and combined with military exercises, would perhaps be the source of patriotic emulation, which surely would have influence over the future.

Moreover, the theoretical and practical study of gymnastics would be of great assistance in the study of physiology—for gymnastics are experimental physiology. Surely, the eminent Professor of Hygiene of the *Faculté* who has demonstrated in his able book on "Labour" the importance which he attaches to this question would not be the last to favour the application. As regards the municipal gymnasiums, my father has shown the necessity of establishing them in three papers addressed to the *Assemblée* and the President of the Republic. Their usefulness, as agreeable places of meeting are too well known; for if one wants a republic of order and liberty, one must occupy himself with the political education of the nation, as well as with its primary education, and we only know how to enjoy liberty through its continual use.

At least, the military exercises, compulsory for every citizen, could be held in the municipal gymnasiums. Four or five large gymnasiums, which one could visit for a small contribution, would render the greatest services, and the town would soon be on the gaining side. Many towns of France, Compiègne, Sedan, Perone, Lille, &c., have taken in this respect the *initiative*.

Long experience has convinced me that gymnastics are more useful to adults and young men than to children. M. Paz rightly observes (Report to M. Simon) "It is time now to remember that no labour can make a nation strong and energetic, but only pure morals, and that the best means to fight against the irregularities of the imagination both in children and men is to subject them all to regular exercise which calms the brain and fortifies the body. If one likes to counterbalance the formidable impediment of the nervous system one must cultivate the muscular system."

The hour is ripe for reformation of this kind. France feels the want of reorganisation, for it does not know what trials it will have to go through; but it is important not to charge the Government too heavily, and the municipalities can do so when possible, and so aid decentralisation. Even the Faculty of Medicine, aided by an authorisation from Government, could open a school for gymnastics which should be to all its pupils a certain tie, the absence of which has often been criticised, for it is sure that the absolute isolation of the country student in Paris is for him a source of danger and peril.

WINTER SESSION AT THE UNIVERSITY OF EDINBURGH.—The session began on Wednesday last with an address by the Principal, Sir A. Grant. During the past session, he stated, the number of students attending in the various faculties has risen to 1,768, being the largest attendance recorded for more than forty years. "The increase," he went on to say, "which has taken place during the past year is chiefly due to the numbers which have joined the Medical Faculty. Everything tends to show the high estimation in which this Faculty is held."

# THE SEWAGE QUESTION.

## SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XXIX.

### AGRICULTURAL VALUE OF SEWAGE.

As might be expected, the nutritive value of a crop which has been raised upon land flooded with sewage is not remarkably high, and this is especially so with root crops and succulent vegetables; for, although the bulk and aggregate weight of the crop are often considerable, yet, the relative proportion of solid nutriment in it is always small; besides, which, the produce is difficult to dry, and from its succulent and immature quality, it is very prone to putrefactive decomposition. It can rarely, in fact, be stored or otherwise treated like the produce of unsewaged land, and must, therefore, be consumed in its fresh or green condition. In commenting on the fact that irrigated meadow land did not yield so nutritious a product as natural pastures, Dr. Voelcker states that this is generally the case with all kinds of produce; for just in whatever degree an abundance of manure was applied, and larger crops were obtained, in that degree would the quality of the crop be inferior. The rule, he says, holds good for wheat and barley, and even turnips. If you want something good you must be content with a small quantity, but if you want much you must take it in a cruder condition. "In fact," to use his words, "the more rapidly produce is grown the less mature it is, and the more likely to produce disorders in the animal economy; whilst bulk for bulk, the poorer the meadow the more scanty the herbage, and the more slowly it grows the better and more nutritious it is."

In the years 1861, 1862, and 1863, experiments were made at Rugby by Mr. Lawes, on the part of the Royal Sewage Commission, of which he was a member, for the purpose of ascertaining the value of sewage grown grass as a means of fattening cattle and producing milk. Two plots of meadow land of different qualities were selected at a distance of a mile from each other,—one called the Five Acre Field, and the other the Ten Acre Field; and each of them was divided into four plots—one plot being left in its natural state without sewage, and the other plots were respectively irrigated with sewage at the rate of 3,000 tons, 6,000 tons, and 9,000 tons per annum. During the first year, the sewage was applied for eight months only, but in the two following years it was applied continuously throughout the year; and the following were the total amount of sewage used, and of green grass obtained per acre in the course of the three years.

TOTAL QUANTITIES PER ACRE IN THREE YEAR 1861, 1862, 1863).

|                |         | Sewage used per Acre. |      |      | Green Grass obtained per Acre. |      |      |      |

|                       | Plot 3.<br>6,000 tons of Sewage<br>per annum. |       |      |      | Plot 4.<br>9,000 tons of Sewage<br>per annum. |       |      |      |
|-----------------------|---|-------|------|------|---|-------|------|------|
|                       | Tons.   | cwts. | qrs. | lbs. | Tons.   | cwts. | qrs. | lbs. |
| Five acre field . . . | 32  | 3     | 1    | 0    | 34  | 2     | 1    | 12   |
| Ten acre field . . .  | 28  | 9     | 3    | 13   | 31  | 1     | 3    | 18   |
| Average . . . . .     | 30  | 6     | 2    | 6    | 32  | 12    | 0    | 15   |

Taking the average, therefore, over the three years in the two fields, it appears that the produce of meadow grass in the plots without sewage was about  $9\frac{1}{2}$  tons per acre per annum, which is equal to about three tons of hay; and with 3,000, 6,000, and 9,000 tons of sewage per acre per annum, the amounts were respectively about  $22\frac{1}{2}$ ,  $30\frac{1}{2}$ , and  $32\frac{1}{2}$  tons of green grass, equal respectively (reckoned according to the percentage of dry substance in each) to about 5,  $5\frac{1}{2}$ , and  $6\frac{1}{2}$  tons of hay.

"The average increase obtained for each 1,000 tons of sewage was, when 3,000 tons per acre per annum were applied, about 5 tons of green grass; when 6,000 tons were applied, 4 tons  $2\frac{1}{2}$  cwt.; and when 9,000 tons were applied, 3 tons  $3\frac{1}{4}$  cwt. of green grass."

Experiments on rye-grass were made in one season only, and comparatively small quantities of sewage were put on, but the results were much about the same, as regards the increase of produce for a given amount of sewage, as with meadow grass.

The composition of the sewaged and the unsewaged grass was carefully determined during each of the years, and it was found that "the sewaged meadow grass as cut and given to the animals, contained a less proportion of dry or solid substance than the unsewaged; and the grass cut during the later portions of the season (both sewaged and unsewaged) contained less solid matter than that cut during the more genial periods of growth. Italian rye-grass in the condition as cut, was also found to be more succulent, and to contain less solid matter when grown with sewage than without it."

"The proportion of nitrogenous substance (and also of impure waxy or fatty matter) was much greater in the solid matter of the sewaged, than in that of the unsewaged grass. The proportion of nitrogenous substance was also much higher in the solid matter of the grass grown towards the end than earlier in the season. The proportion of indigestible woody fibre was much about the same in the dry substance of the unsewaged and of the sewaged grass. It progressively diminished as the season advanced, and was generally lower in the dry substance of the Italian rye-grass than in that of the meadow grass."

The results are shown in the following table :—

PER CENTAGE OF DRY SUBSTANCE IN THE UNSEWAGED AND THE SEWAGED GRASS.

|   | 100.00                | 100.00                                       | 100.00                                       | 100.00                                       |

The most remarkable fact is, that the proportion of nitrogenous constituents rises with the quantity of sewage used; but this affords no indication of the nutritive power of the grass, except that the milk yielding qualities were not in proportion to these matters—weight for weight, indeed, the earlier crops of the season, which contained the least nitrogenous matter were by far the most nutritious, and so, also, was the unsewaged grass which yielded the smallest proportions of these substances. "At one time," says Dr. Voelcker, "it was generally believed that the amount of nitrogenous matter was the measure of the nutritive quality of the produce, and Professor Way, with other chemists, having found in the grass and hay of irrigated meadows more nitrogenous matter than in ordinary produce, arrived at the conclusion that it was really more nutritious. But, now the tide has set in a different and more reasonable direction—a direction that is borne out by practical experience. Now, an excessive quantity of nitrogenous produce is regarded rather as an indication of unripeness, of which one defect is a deficiency of sugar." It would seem, indeed, that the nutritive power of such food is very much dependant on the proper maturation and elaboration of the tissues, whereby the digestibility and assimilability of the constituents are ensured.

For the purpose of testing the fattening powers of the sewaged and unsewaged grass, experiments were made on ten Hereford oxen, which were tied up in a shed and fed upon the green grass—two being supplied with unsewaged grass, and eight with the sewaged grass of the five acre field cut indiscriminately from the three plots, irrigated respectively with 3,000, 6,000, and 9,000 tons of sewage per acre per annum. In the year 1861, the animals had grass alone for the first sixteen out of the twenty weeks of

the whole experiment, and they had oil-cake in addition (four pounds per head per day), during the remaining four weeks. The object was, to try grass alone in the first season, and the result was very unfavourable, so much so, that the commissioners said, in reporting of it, that "it is quite obvious from the table given that grass of the description in question, is not adapted for the fattening of oxen without the addition of other food. Indeed, one of the animals on the sewaged grass weighed fifty-two pounds less at the conclusion of the experiment, than at the commencement of it; and the maximum increase of any one of the oxen was 103 lbs. in the sixteen weeks, or at the rate of rather less than 6½ lbs. per week. Taking the average of the two and the eight oxen respectively, those upon unsewaged grass gave scarcely 2½ lbs., and those upon sewaged grass scarcely 2¾ lbs. increase per 1,000 lbs. live-weight per week; whereas, feeding on good fattening food, such oxen should give 9 to 10 lbs. increase per 1,000 lbs. live-weight per week. In fact, these very animals did increase at this, and even a higher rate, during the subsequent four weeks, when they had, in addition to the grass, 4 lbs. of oil-cake per head per day." Having these facts before them, the commissioners, in 1862, gave oil-cake in addition to the grass from the commencement of the experiment (using ten oxen, as before), and the quantity of oil-cake amounted over the whole period of twenty-three weeks, to 3½ lbs. per head per day. The results of all these experiments are shown in the following table:—

RESULTS OF EXPERIMENTS IN THE FEEDING OF OXEN ON GREEN GRASS ALONE, AND WITH OIL-CAKE IN ADDITION.

|  | 1861.            |                | 1862.            |           |                |           |

| Consumed to produce 100 lbs. increase of live weight . . . . . | 23,669           | 24,735         | 6,213            | 210       | 6,883          | 195       |
| Dry substance in . . . . .                                     | 6,246            | 5,000          | 1,389            | 186       | 1,141          | 172       |

So that in both years a greater weight of the fresh sewaged grass was consumed per head per day, and per 1,000 lbs. live weight per week, than of the less succulent unsewaged grass; but the dry or solid substance contained in the latter (reckoning all that was eaten), was less than that in the former. Again, more of the sewaged grass than of the unsewaged, was required to produce 100 lbs. increase in live-weight; though the amount of dry substance contained in the sewaged grass so required, was only about four-fifths as much as that in the unsewaged grass. But when, as in 1862, a fair allowance of oil-cake was given in addition, very much less both of fresh food and of dry solid substance of food were required to produce 100 lbs. increase in live-weight, than in 1861 with grass alone; and considerably less of the dry or solid substance of the more succulent sewaged, than of the drier unsewaged grass was required. In the summary of these results, the commissioners say that, "when cut grass was given alone, the result was very unsatisfactory; but when

oil-cake was given in addition, the amount of increase upon a given weight of animal within a given time, and for a given amount of dry substance of food consumed was not far short of the average result obtained when oxen are fed under cover on a good mixed diet;" and as regards profit, they say that "the money return, whether reckoned per acre, or for a given amount of sewage used, was much less with fattening oxen, than with milking cows,"—the value, in fact, per acre of the increase of live-weight, at 4d. per lb., was only £1 9s. 4d. for the unsewaged grass, and from £2 4s. 10d., to £4 19s. 2d. for the sewaged in 1861, when no oil-cake was given; and even in 1862, when the results of better feeding were obtained, the value for the unsewaged land, exclusive of oil-cake, was but £3 9s. 10d. per acre, and of the sewaged from £11 1s. 8d., to £12 18s. 1d. per acre.

## Transactions of Societies.

MEDICAL SOCIETY OF LONDON.  
MONDAY, OCTOBER 23, 1871.

MR. WEEDEN COOKE, Vice-President, in the Chair.

MR. SPENCER WATSON showed a case of  
TRAUMATIC DISLOCATION OF THE CRYSTALLINE LENS INTO THE ANTERIOR CHAMBER.

Glaucomatous symptoms were set up, with very severe pain and intra-ocular tension. The lens was extracted through an incision made in the ciliary region of the sclerotic at the lower and outer side. The result was good, useful vision being retained four months after the operation. This operation was performed in consequence of the generally unfavourable results following the scoop and flap extractions in similar cases, and partly from the occasionally good results following rupture of the eyeball, and escape of the lens through a rent in the margin of the sclerotic. The choroid had been injured by the accident.

CASE 2.—S. A., æt. fourteen. Congenital displacement of both lenses; when the pupils are natural in size the irides are tremulous, and when the eyeball is moved inwards, the pupils become oval, and the plane of the iris near the pupil is obliquely inclined on the inner side, as if from the lens pushing it forwards; at that part there is a slight divergent squint, and the child's aspect is peculiar. The father's sight is defective, but the mother's and a younger child is good.

MR. HENRY SMITH then related an interesting case of  
LITHOTRITY FOLLOWED BY LITHOTOMY.

The crushed stone was shown. The patient was a healthy country gentleman, æt. seventy, who was determined to have lithotritry performed. The bladder was healthy and tolerant of sound, the urethra capacious, and the stone of a size convenient for crushing. The stone was seized without trouble, and crushed in a few seconds, in forty-eight hours, violent inflammation came on, and his life was placed in peril. In ten days he was free from danger, and then consented to have lithotomy performed. The lateral operation was done, and he made a speedy recovery. Mr. Smith thought that a second operation of lithotritry would have proved fatal. Sir B. Brodie has pointed out that sometimes a second crushing operation removed the symptoms of inflammation.

MR. BRYANT called attention to the extreme importance of a course of sounding. In stricture and stone in the bladder, especially in the latter, the passage of a sound may set up urethral fever. In a case of stone, for which lithotritry was proposed, he sounded several times, on the third occasion, the lithotrite failed to detect the stone, and the operation was postponed. Rigors and much constitutional fever set in, and the patient died on the fifth day, disease of the kidneys was present.

MR. SMITH admired Mr. Bryant's courage in bringing the case forward, two years ago he had in King's College Hospital, a strong healthy agricultural labourer, with a small stone in his bladder. The stone was taken up with a lithotrite, measured, and let fall again, no violence having been done, severe inflammation followed, followed by death in ten days.

AN INGENIOUS METHOD FOR APPLYING DRY COLD TO THE  
EYE

was shown by MR. WATSON. The ordinary india-rubber air balls were filled with water and placed in a basin containing iced water, and applied to the eye, being changed at intervals. Different sizes could be used, and they adapted themselves well to the part.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.  
TUESDAY, OCTOBER 24th, 1871.

MR. CURLING, F.R.S., PRESIDENT, IN THE CHAIR.

MR. F. LE GROS CLARK, F.R.C.S., related a  
CASE OF LARGE BILIARY CONCRETION IN THE ILEUM.

The author gave the details of a case occurring in a patient, aged fifty-eight, who was seized with abdominal pain and bilious vomiting, accompanied by constipation. A hard tumour was to be felt in the right hypochondrium. There was no abdominal tenderness or distension. On the eleventh day the vomiting became stercoraceous. Two days later the bowels were open and the vomiting ceased until ten days later, when it recurred, and continued at intervals during a week. For three weeks after this time the bowels acted daily, and there was no sickness. The patient was then seized with severe abdominal pain and vomiting; the abdomen was tender, especially over the region of the cæcum, where a hard tumour could be felt. Death took place two months from the commencement of the first attack. At no period of her life had the patient suffered from jaundice.—The post-mortem examination revealed the existence of extensive peritonitis. Two large gall-stones occupied the ileum close to the valve. An ulcerated opening in the small intestines had permitted the escape of several small gall-stones into the peritoneum. The gall-bladder was healthy; there were no adhesions between it and any portion of the intestines. There was no trace of any ulceration either in the gall-bladder or in the neighbouring intestines.—The concretions measured 1 in. in length and 4 in. in circumference. They seemed moulded to the shape of the ileum. On examination, it was found that the stones were composed of 95 per cent. of cholesterine, and that nothing had been added to them in the intestines. The gall-ducts were dilated and thickened. The author drew attention to the singular absence of any proof that these concretions had passed by ulceration from the gall-bladder to the duodenum, though this is the only way in which such large bodies could have entered the intestines.

MR. DE MERIC asked what were the grounds of the diagnosis with regard to the cause of the obstruction. He had been consulted in a somewhat similar case, were, however, there was no post-mortem, so that he was left in the dark as to its exact causation.

DR. A. P. STEWART remembered a patient in the Middlesex Hospital with obstinate stercoraceous vomiting. No relief could be obtained, and after death a gall-stone as large as any of those exhibited was found impacted in the ileum. It was smooth and rounded, and constituted a complete barrier to the passage. There were distinct marks of ulceration in the gall-bladder and duodenum. The year before last he had seen a lady with intense pain; suddenly she obtained rest, but again the pain came on, and again relief followed. Next day she passed a calculus the size of a pigeon's egg. It was almost certain this had passed by the ductus communis.

DR. HABERSHON said such cases were interesting for their rarity and the difficulties of diagnosis. Some years ago he had a somewhat similar case in a lady over fifty years of age. She had pain and bilious vomiting, and died in ten days. They found a large gall-stone in her jejunum. There had been no peritonitis, and no stercoraceous vomiting. There were adhesions between the gall-bladder and duodenum, but no regular cicatrix.

MR. LE GROS CLARK said there had been great difficulty in coming to any diagnosis, and that it was only reached by way of exclusion. There were no inflammatory symptoms, and no signs of malignancy, so he considered the obstruction due to scybala, and directed his treatment accordingly.

MR. J. WARRINGTON HAWARD communicated a paper  
ON ETHER AND CHLOROFORM AS ANÆSTHETICS.  
The paper commenced by stating that, it having been suggested to the author that the statements of Dr. Bigelow and other American surgeons showed that ether as an anæsthetic had

been to our detriment neglected, he had during the past year, practically investigated the subject, and had arrived at the conclusion that ether was, for several reasons, to be preferred to chloroform. Of these reasons, the strongest was the greater safety of ether, for by using it the chief, and in skilled hands probably the only, cause of fatal cases of chloroform inhalation was excluded—i.e., paralysis of the heart; ether being a stimulant to the heart's action, and uniformly improving the pulse. The second was that ether, from its stimulant quality was antagonistic to the effects of the shock of an operation, which the author maintained, and quoted cases to show, was not abolished by rendering the patient insensible. A third was the greater liability of chloroform than ether to produce after-sickness. The principles and mode of administering ether were then described, and it was shown that if these were attended to, the production of anæsthesia by ether was as easy and certain as by chloroform and required but little more expenditure of time or the drug. The only cases to which ether was not so applicable were operations upon the mouth, in which an inhaler could not be used, and where it was necessary to re-administer the anæsthetic as rapidly as possible without an inhaler. There were two appendices to the paper: the first consisting of a table of fatal cases of chloroform; the second, of a table of ninety-seven cases in which the author had administered ether, including amputations, excisions, perineal section, lithotomy, lithotrity, staphyloraphy, vesico-vaginal fistula, ligature of piles, and other operations. Especial note was taken of the occurrence of after-sickness, and the only approach to it was that in one case, after an operation for recto-vesical fistula, the patient vomited once, an hour after the operation.

The PRESIDENT regretted that no notice had been taken of the proposal of the Society's committee to use the mixed vapours of alcohol, ether, and chloroform.

MR. SPENCER WELLS said the mixed vapours of ether and chloroform had been employed at Vienna, but it was found that the ether evaporated first, and that after it had gone the patient was drenched with the chloroform. He had long felt objections to chloroform, especially as regards the vomiting it produced. This was particularly objectionable in many of the operations he had to undertake, especially in the abdomen and vagina. He had tried ether on the advice of Dr. Keith, of Edinburgh, but it was so troublesome that he was glad to take to bichloride of methylene. This he thought the best anæsthetic; sickness after it was rare. Some said it was only a mixture of chloroform and hydrochloric ether; that might be so, but so long as it suited his purpose he did not care what it was chemically. It was best given by Jiunker's apparatus.

DR. DAY said he had frequently given bichloride of methylene for Mr. S. Wells, and was much satisfied with it. He entered at length into its chemical characters, and exhibited the apparatus referred to.

DR. SANSON said the data available did not admit of an accurate estimate of the relative danger of chloroform and ether. He differed from the author alike in his estimate of ether and chloroform. He could not call the former safe. Relatively, chloroform was more manageable and less nauseous than ether. He considered the great danger of chloroform lay in its depressing action on the heart; but this could be avoided: It was true ether and chloroform did not go off together, but alcohol acted by restraining them both. By injecting morphia C. Bernard found that much less chloroform was required to produce anæsthesia. It was best to give morphia subcutaneously first, and chloroform afterwards, or to administer chloroform and alcohol together, or chloroform first and ether next, as he had first proposed some time ago.

MR. HOLMES said he had tried ether some years ago. It required twice the time chloroform did to produce anæsthesia; but this was an insignificant trouble if it were safer. He tried to favour the escape of the vapour by using a hot sponge, and it blistered the face of the patient. Violent convulsive movements were also induced by it in certain patients. Its relative safety was doubtful, for the statistics were more than suspicious. It was really impossible to avoid danger in the production of anæsthesia.

MR. BRUDENELL CARTER had tried ether on himself, and the taste of it hung about him a long time. This was an objection to its use.

DR. HUNTER said if they used other narcotics they must look to the lungs as well as to the heart. In one of these compound cases he had nearly met with a fatal result. It was best, he thought to use morphia when the effects of the chloroform were passing away.

MR. CLOVER remembered that sickness followed the use of ether when that anæsthetic was first used in this country. He had been in the habit of giving nitrous oxide first, and then ether, as the great difficulty was to get patients to inhale it freely. As to the giving of chloroform, the modes of giving it were of the utmost importance. He was convinced that a mixture of 4 per cent. of chloroform with air had a totally different effect from a mixture of 6 per cent.

MR. HAWARD, in reply, pointed out that he was no special advocate for ether. He had tried it, and he had been struck with the results as being different from those commonly reported. The evidence was rather in favour of its safety. If, therefore, it could be easily employed, it would be well to use it; and he had shown that it could. The pulse really improved under its use. He had seen the combined fluids used; they produced excitement. No peculiar unpleasantness was left behind by ether.

## THE HAMPSTEAD HOSPITAL ENQUIRY.

### SPECIAL REVIEW.

(Prepared expressly for the MEDICAL PRESS AND CIRCULAR.)

#### No. I.

IT would be easy to underrate, but hardly possible to overestimate, the significance and the importance of this investigation, which, at the onset, forced itself into the rank of "*les causes celebres*" of our times. The prodigious impression not in this metropolis alone, nor even in England alone, but far and wide over the civilised world, which the opening record of this enquiry produced will not soon be forgotten. Some idea may be formed of the intensity of the emotion, roused by the charges brought by the three assistant medical officers, Messrs Aikman, Kynaston, and Greaves, against the Hospital, the nurses and the whole staff, and inferentially against the managers, from the violent language and violent conduct used by the offended public against the nurses and the Hospital staff. Letters have been received by the trained and educated ladies, conducting these duties, from educated men, very violent—and if not grounded on sufficient evidence, frantic in the excess of vituperative and execrative expressions. The public feeling has been deeply stirred. The Government has been appealed to, and the whole press of the country have watched every phasis and every step of the inquiry with unabated patience.

If the charges had been sustained, the three medical assistant officers would have done real service and have merited the thanks of the community; if the charges were not sustained they would have incurred grave responsibility. If the evidence fixed the blame of the alleged delinquencies on the accusers themselves, the profession to which they belong would be scandalised. If the evidence showed disingenuousness, still worse a spirit, reckless of the truth, simply for the sake of vengeance, there would be no alternative but to award them the severest censure. We must therefore approach this subject in a calm and thoughtful mood. The history of the hospitals, of which that at Hampstead forms one, may be epitomised.

The Metropolitan Asylums District Board was brought into existence by Mr. Gathorne Hardy's Act of 1867, which had for its object the establishment in the Metropolis of asylums for the sick, insane, and other classes of the poor, and for the distribution over the metropolis of those portions of the charge for the poor

relief which were incurred for the treatment of the dependent sick poor. By this Act the then Poor-law Board was empowered to form two or more Unions a district and constitute a number of managers into a corporate body consisting of elected and nominated members; the tenure of office to be prescribed by the Board, but the nominated managers may not ever exceed one-third of the prescribed number of elective managers. The whole metropolis having by this authority been consolidated into a single district, forty-five managers were elected as representatives of the various London Boards of Guardians, and fifteen members were nominated by the Board; and the first meeting for dispatch of business was appointed to take place at the Board of Works, Spring Gardens, June 22nd, 1867.

At this meeting Dr. Brewer was elected the chairman, and he has retained the post from that time to the present. Of the sixty managers, ten were on the Commission of Peace, seven were medical men, and all the rest were either chairmen of their respective Boards locally, or known for active work in visiting and assisting the poor; or were heads of some charitable organisation for the relief of the sick.

In July of the same year it was determined to apportion the detail of the work to be done by constituting the whole Board into seven standing committees, of which the chairman of the Board and vice-chairman should be extra members. The two committees to which we must specially refer were the committee for securing the sites and superintending the erection of the needful number of small-pox hospitals of which Mr. Timothy Holmes, who had been employed by the Government in the survey and inspection of Hospitals was the chairman; and the Fever Hospital Committee of which Dr. Sibson (equally well known for his public services) was the chairman. The committees were severally charged to report to the Board the number of persons of either sex of each class for whom accommodation would be required. On the 24th of August, the number of insane to be provided for was calculated at 3,000, and the actual number has proved but little in excess of the estimate. The Small-pox Committee estimated that two small-pox hospitals, each fitted with about one hundred beds would be adequate for the demand of the District; and the Fever Committee reported that two hospitals, each provided with 200 beds would suffice for the fever cases of the district. Subsequently upon carefully estimating the numbers which different localities and densely peopled centres sent to the Fever Hospital and the foul wards of their own parishes, it was determined to increase the number to three hospitals, each hospital being within a three mile radius of the most populous portions of the metropolis. The sites chosen were Hampstead in the West; Homerton in the East; and Stockwell in the South. The two sites of Leavesden and Caterham being selected for the erection of asylums for the imbecile poor. It was determined to adopt in all the Pavilion style of building, rendering each asylum as complete in itself and independent of external aid as possible. Whilst the Fever Hospitals were just half completed, the relapsing fever became epidemic, and the Poor-law Board and Privy Council called on the managers to make provision for the sufferers. The means suggested and adopted was to authorise the authorities of the Fever Hospital, then rapidly filling with relapsing fever patients, to erect

a large double ward at the rear of their permanent building, capable of containing sixty beds at least. This was to consist of iron, lined with wood, the interstice to be filled with felt or sawdust. In one fortnight the erection was completed and the managers found the accommodation would be insufficient.

It had so happened that the Poor-law Board had sanctioned the managers purchasing a site at Hampstead, but greatly objected to the managers erecting the third Fever Hospital, deeming the two, already in progress, ample. Under these circumstances the managers proposed to erect temporary pavilions for 120 beds on their site at Hampstead for the epidemic, and in about thirty days they opened three wards. They were most unwilling to press the Fever Hospital authorities to increase their accommodation, as they found that the great accumulation of one class of fever told severely on the health and life of the medical attendants and nurses. No sooner were the wards at Hampstead full than the epidemic began to decline and the provision for the sufferers being adequate the visitation of the fever ceased. The pavilions of iron lined with felt and finally with wood, and the completeness of the administrative department for the 120 up to 180 beds, for which the whole was ultimately designed, afforded so admirable a provision against any sudden attack of zymotic disease, whilst the permanent hospitals were in process of erection, that the managers determined not wholly to shut up the hospital, but to keep it in the occupation of a trusty officer. Six months had hardly elapsed before small-pox began to threaten, and in November, 1870, the managers opened Hampstead wards for the new epidemic. But the severity of the visitation exceeded anything which had been contemplated, and the whole metropolis (ceasing to make provision locally) made a run on the Hampstead wards. In ten months five thousand six hundred small-pox patients found refuge in these pavilions and it was not till the managers had provided two thousand three hundred beds that the supply became adequate to the demand and the epidemic began to decline. The evidence discloses the pressure under which the managers struggled to increase the accommodation which was demanded by the importunity of patients craving admission and discloses the practical difficulty of confining to one class—the rate-supported poor—the benefits of hospitals for zymotic disease in serious epidemics. The actual number of the class ordinary self-supporting who entered Hampstead hospital in the earlier stage, amounted to sixty-seven per cent. of admissions. Workmen were, during several weeks of the severe winter, erecting these wards by gas light as late as eleven at night and commencing work in the morning by gas light, the progress was undoubtedly rapid, but it was clearly impossible for the administrative department to expand proportionally to the expense of bed-accommodation. It was indeed a race run with the epidemic; and nothing but the unanimity and untiring zeal of the officers and nurses could save the hospital from breaking down altogether. It is a matter of doubt if the authorities were warranted in admitting patients beyond their capabilities of providing suitably for each case, the excuse was that some came to the gate imploring to be admitted—others were found in so exhausted a condition in the ambulance, that Dr. Greaves (the medical superintendent) believed the refusal to admit would be fatal, and in the instance wherein an

applicant was refused in consequence of the hospital being full the complaint from the parish, which had sent him, in spite of the warning that there was no vacant bed at the hospital, was taken up and spread alarm.

As the epidemic went on, the managers hurried forward the completion of the two hospitals at Homerton, and the two hospitals at Stockwell, appropriating all four for the reception of small-pox. The last means adopted was to take the old workhouse at Islington for the reception of some convalescents from Hampstead, and to get up the Dreadnought for some of the convalescents of Stockwell and Homerton, at both which additional tent wards were erected, and by these means 2,300 beds were provided and about ten thousand cases treated.

The epidemic had retreated; and the hospitals were being gradually relieved when the country was roused by the letter to *The Times*, of Tuesday, 29th August, 1871, containing the following alarming charges against the Hampstead Hospital.

*Times*, Tuesday, 29th August, 1871.

SEVEN CHARGES.

1. Delirious patients, more particularly children, tied down when their bodies were covered with eruption.
2. Strait waistcoats have been used with the same motive.
3. Patients in an acute ward have been provided with a totally inadequate supply of milk and beef tea for their use during the night.
4. On making the morning visit, we have been informed by the nurse in charge, that the patients of her ward on low diet have been kept without food of any kind from seven a.m. till three p.m.
5. Complaints have frequently been made to us by both nurse and patients, that food supplied has been totally unfit for consumption.
6. Children have been found dead in bed by the medical officer and the nurse of the ward ignorant of the fact, this through the totally inadequate number of nurses provided for the necessities of the hospital, and not through the neglect of the individual on duty.\*
7. The body of a patient who died at midnight, being in the most offensive possible condition, was removed into the bath-room of the ward, and there kept until the middle of the following day, instead of being at once carried to the dead house.

In addition one child, if not more has been lost, and all traces of it gone, although at one time reported as convalescent.

By our continuous opposition and repeated complaints to the medical superintendent, we have done some little good; but our task has been a most unthankful one, and has brought us no little odium although one would have expected a contrary effect.

Had we remained, we should have trusted to our own energies to have kept down mismanagement, but we are no longer wanted, and as much remains undone in the way of management, we request you to publish this letter for the reason above stated.

W. GREAVES.  
ALBERT E. KYNASTON.  
JOHN AIKMAN.

SEPT. 12.—Our complaints about the maltreatment of the patients were endorsed by the daily reports which are in the hands of the hospital authorities.

W. GREAVES.  
ALBERT E. KYNASTON.  
JOHN AIKMAN.

These charges are prefaced by the allegation of their being made solely on public grounds.

\* Under this head came complaints of lousey heads, and insufficient linen, and unchanged sheets and shirts, and defective cooking and hard meat, and sour milk, and no water supply.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, NOVEMBER 8, 1871.

### THE MEDICAL ASPECT OF THE FRANCO-GERMAN WAR.—No. II.

*Hospital Hygiene.*—On this subject we have little to learn from either French or German. Ventilation would seem to be ignored by the one and the other; and *cleanliness* to have a very different significance from what it has in England. In Dr. McCormack's ambulance in the Caserne d'Asfeld, for example, the Intendant-General who visited it is said to have been highly pleased with all arrangements “excepting the open windows—at that he stood *aghast*, protested strongly, and told us a *courant d'air* like that would kill our patients” (p. 11). Had the hospital been under his orders, as all those in the French army are, he would, doubtless have given orders against the admission into the wards of a *courant d'air*; and the natural result would have been frightful mortality by hospital diseases. In those under the National Society, however, the entire direction was in the hands of the Chief Surgeon, so that when insanitary conditions did exist they arose from circumstances of an altogether unavoidable nature. It was found, for example, that where pyæmia occurred, “the rooms were greatly overcrowded, that notwithstanding our keeping doors and windows widely open, thoroughly adequate ventilation was not attainable; that it was impossible to change our straw as often as would have been desirable, and that from the want of clean linen and sufficiency of trustworthy attendants, all our efforts in that direction did not suffice to ensure ideal cleanliness either of the patients or their surroundings” (p. 112). This admission has a most important bearing upon the etiology of hospital diseases. The state of the German military hospital at Anoux la Grange is described by Dr. Mayo as “disgraceful.” Dr. Sandwith, C.B., saw during his tour “a great deal to admire and a great deal to wonder at in the admirable organisation and skill of the Germans in every department;” but is bound to add “that this important detail (hygiene) was sadly neglected.” Miss Lees, who had undergone a system of training in the great military hos-

pital of *Val de Grâce*, and had served in military hospitals with French and Germans during nearly the whole war, mentions several particulars, clearly showing that hygiene was less attended to in the latter than in the former. Some, for example, had double windows which were never opened. Where the American wooden hut system was adopted for reserve lazarettos, the Germans had all the windows carefully nailed up at the commencement of winter, leaving only one or two small ventilators moveable at the top of the building. At Nancy the air in some of the hospital huts was so utterly foul and corrupt, that a feeling of utter nausea came over her each time she entered them” (p. 172). Again, “Nothing could be more horrible than the air of some of the stationary hospitals in Germany in time even of peace.” Of course, there are some exceptions, but that such conditions as are here described should at this time of day exist anywhere is the reverse of creditable to the authorities directly concerned.

*Scenes.*—Of the horrible scenes presented in some of the military hospitals of both Germans and French the public will probably hear comparatively little. A terrible agglomeration of sick and wounded is described at Sedan. One man with small-pox, “about forty had wounds of the most dreadful nature with profuse and exhausting discharges; some of them in a state of mortification, and the remaining cases of fever, diarrhoea, and dysentery. Add to all this that we did not have doctors and nurses enough to administer to their wants,” &c., &c. (p. 103). Then, again, at the same place numbers of wounded had to lie for some days “in their blood-stiffened, dirty uniforms on straw, as we had not managed to collect a few mattresses in the village, and with great difficulty had been able to find sheets, blankets, and shirts for the serious cases” (p. 111). At St. Privat “among the wounded there were forty-five cases in which amputation had been performed, and not one of them had a bed to lie upon. All of them lay upon straw. Many of them had not a shirt, but lay naked with a sheet or blanket thrown around them” (p. 157); and yet with all these discomforts the men so situated were “doing well.” After a series of severe battles it is utterly impossible with any staff that can be entertained to avoid some such scenes as are described, and perhaps, after all, the wonder is that those which did occur were so rare and upon so small a scale. It is easy for writers in civil life to cavil and find fault, but let these same writers betake themselves to actual service in the field, and perhaps their criticisms would for the future become more lenient.

*The statistics* of the Franco-Prussian War have yet to be published. Some few particulars have, it is true, been given, but they are so indefinite in their nature as to be of little real value, while the want of plan in their arrangement renders comparison altogether out of the question. The few returns hitherto given represent very imperfectly the degree of severity or precise nature of injury; nor are the conditions under which the wounded have been received and treated detailed. The returns of the hospital in the Caserne d'Asfeld at Sedan are cases in point: they show that of 472 cases of wounds admitted 103 deaths took place, and that of 109 operations of different kinds performed, fifty were followed by death; but among the first are included, indiscriminately, gunshot wounds of the head, face, and neck, penetrating wounds of the chest, abdomen, pelvis and joints, sprains, burns,

contusions, &c.; while among the latter are disarticulations, resections, amputations, and ligatures. Of the latter we have, indeed, more definite information than is furnished in regard to any others. In all cases the operation was performed for secondary hæmorrhage; of two cases, when it was performed in the subclavian artery, death followed in both; of two of common carotid artery, in one; and in the only case of the femoral artery. The dorsal artery of the penis was severed in one case, and in it successfully.

## Notes on Current Topics.

### Comfort for the Teetotallers—Hard Work, no Strong Drink, and Perfect Health.

THE *Edinburgh Courant* says:—

Captain Huyshe, in his description of the journey of the Red River Expedition, gives some very interesting accounts of the toil which it endured and the obstacles it overcame. One of the most toilsome obstacles was that of a "portage," where the boats must be hauled upon log rollers, over a road cut through the woods, from one lake or river to another. There were forty-seven such portages between Lake Shebandowan and Fort Garry. The boats were stoutly built, 25 ft. or 30 ft. long, and 6 ft. or 7 ft. wide. The guns weighed 200 lb. each, the barrels of pork each 2 cwt., the flour barrels 120 lb., the biscuit barrels 100 lb.; and these heavy burdens were carried on the backs of the men. Some of them used "portage-straps," consisting of a band of leather  $3\frac{1}{2}$  in. broad, which rests upon the forehead, while its two ends are fastened round the package behind, which is held in its place by the hands. Others preferred letting the burden rest on a pair of slings between two poles, which were supported by two men, each man walking between the poles, as in a sedan-chair, and either holding them in his two hands or suspending them by straps to his shoulders. The men endured their great fatigues and continual exposure to the wet in the most praiseworthy manner; none of them complained, and none suffered in health. They had not a drop of alcoholic or fermented liquor all the way; tea or coffee, with sugar, was the only stimulant allowed. Their daily rations were, of biscuits, 1 lb.; of salt pork, 1 lb.; and one third of a pint of beans, or  $\frac{1}{4}$  lb. of potatoes. Upon this fare, alike for officers and soldiers, and upon the teetotal principle with regard to drink, they worked fifteen hours a day, as hard as ever any man could work. They were "constantly wet through, wet sometimes for days together." Yet, we are told, "they looked as healthy and cheery as possible, and there was not a sick man amongst them." Captain Huyshe is decidedly of opinion, after this experiment, that the practice of issuing spiritations to British troops in the field should henceforth be totally abolished.

### Professor Huxley on Motion and Consciousness.

On the 30th ult., Professor Huxley commenced at the London Institution a course of eight lectures on the elements of the physiology of bodily motion and consciousness. The lecture was devoted to the phenomena of motion and consciousness exhibited by the living body, and the general conditions on which they are depen-

dent. Having explained the distinction between the phenomena of motion and those of consciousness, the lecturer showed that all movements whatsoever might be absolutely involuntary, and that only a certain class could be separated as being under ordinary circumstances subject to the dictation of the will. Some forms of bodily motion were not capable of being affected by the will, others were entirely dependent upon voluntary operation, and some were partly voluntary and partly involuntary. His object was not to account for the connection between bodily motion and mental states, but to analyse them, and to show the steps that intervene between bodily motion on the one hand, and the states of consciousness on the other. The lecturer then demonstrated the chain of operations involved in the reception by the ear of a request to raise the arm, and its ultimate result, and afterwards dwelt on the structure and properties of contractile matter.

### Doctors and Lawyers.

A GOOD illustration of the propriety with which lawyers can taunt the medical profession with their differences in legal testimony, is contained, says the *Pacific Med.* in the following statement: The decisions of Lord Giffard, Chief Justice of England, in appeals from the lower courts, for the first six months of the year 1870, cover forty-one cases. The judgment of the lower courts was affirmed in only seventeen, modified in five, and positively reversed in nineteen. The *Phil. Med. Times*, in commenting on the matter, remarks that a physician who is called into court will see in six hours more quarrelling by lawyers over points of difference of opinion than among his brother practitioners in six months.

### A Word to Chicago.

CHICAGO lives! Next to the terrible interest of the burning of Chicago is the life that still exists amid the ruins, and the energy that sets about to repair it. Advice to such men may seem futile, but as our exchange copy will in all probability be received by our brethren there, we would venture to say that the sad lesson of the fire should lead those about to rebuild the city to consider how the materials used may best be made non-inflammable. It is a problem that ought to be solved before Phoenix-like, the city rises from its ashes.

### The Sanitary State of Ireland for the past Quarter.

*Births.*—The births registered during the second quarter of the present year amounted to 40,855; affording an annual ratio of 1 in every 33.1 or 3.02 per cent. of the population. The average for same quarter of the previous five years was 40,004.

*Deaths.*—There were 22,446 deaths registered during the quarter; 1 in 60.2, or 1.66 per cent. of the population. The average of same quarter of the previous five years 23,823.

It is but too apparent from the foregoing figures that the registration of births and deaths is still very imperfect, the annual ratio of births to the estimated population in England being about 1 in 29 or 30, and of deaths 1 in 44 or 45; whilst in Ireland, according to the present return, the ratios are—for births, 1 in 33.1; and for deaths, 1 in 60.2. The registration of marriages under the provi-

sions of the 26 and 27 Vic. cap. 90, it is greatly to be regretted, is still more unsatisfactory.

*Estimated decrease of the population.*—The number of births being 40,855; the deaths 22,446; and the number of emigrants 32,709. A decrease of 14,300 would, therefore, appear to have taken place in the population of Ireland during that period.

*Pauperism.*—The average number of persons in Ireland receiving in-door relief on Saturdays during the quarter was 45,991, against 50,168 for 1870. The average out-door relief was 24,446 against 21,614 during 1870.

*Health of the people.*—The state of the public health during the quarter was, on the whole, satisfactory. The number of deaths registered was 1,377 below the average of the corresponding period of the previous five years, and 1,045 less than in the second quarter of last year. The majority of the Registrars have reported favourably as to the healthfulness of their districts, and the comparative immunity from epidemic disease. As small-pox was epidemic in Great Britain, and no quarantine regulations had been adopted to prevent the importation of the disease, fatal cases occurred in various parts of the country. Since the introduction of the Compulsory Vaccination Act in 1864, the deaths from small-pox have decreased in a remarkable manner. If the disease when imported should, unhappily, extend over the country, such an event could not seriously depreciate the protective powers of vaccination, for the Compulsory Vaccination Act only affects those born after the 31st of December, 1863; it has no retrospective power. There had been always a large proportion of the people hostile to vaccination—so at the present time the number of adults unvaccinated, and therefore unprotected, must be very considerable. It is much to be regretted that information as to previous vaccination is not always furnished in the returns. Twenty-nine of the Registrars report the presence of small-pox in their several districts. In Longford two fatal cases of small-pox occurred, they were "attacked immediately after their arrival from Dublin. The disease extended no farther." In Dundalk "about 13 families have been attacked, and there have been 5 fatal cases registered, 1 in the workhouse, and 4 in the town—1 young man aged 20, said to have been vaccinated; 1 young girl aged 17, ditto; 1 little girl aged 10, ditto; 1 child at workhouse, aged 7 months, not known; and 1 child, 3 months, unvaccinated." At Queenstown "there were three deaths from small-pox during the quarter; the disease was imported in ships outward bound from Liverpool. As far as could be ascertained none of the persons had been vaccinated." In Carlow "one case of small-pox is reported in which the patient passed through the illness favourably and recovered. The disease in this instance was imported from Liverpool through the medium of some clothes worn by a victim to the malady." The Poor-law Medical Officers have shown a praiseworthy zeal in carrying out the provisions of the Compulsory Vaccination Act, and the fact that up to the present time (notwithstanding the many cases of small-pox imported from England and Scotland into the country) the disease has not spread to any great extent, shows how valuable their labours have proved to the community. As before stated, there was a general absence of epidemic disease. In some districts scarlet fever prevailed, especially in those where sanitary laws were ignored. There has been in some parts of the country a considerable improvement as regards sanitary

arrangements. The numberless complaints of deficient sewerage, imperfect supply of water, &c., merely show that the provisions of the Sanitary Act of 1866 are not carried out. The success of the Compulsory Vaccination Act proves that a law when properly administered will prove effective.

*Deaths in Provinces.*—There were registered in Leinster 6,313 deaths, 1 in 52 of the estimated population; the number registered in Munster was 1 in 60; in Ulster, 1 in 62; and in Connaught, 1 in 74. The average ratios afforded by the deaths registered in the second quarter of the previous five years were—in Leinster, 1 in 50; in Munster, 1 in 58; in Ulster, 1 in 57; and in Connaught, 1 in 73.

### Unqualified Medical Practitioners.

LAST week the Coroner for Middlesex held an inquiry respecting the death of Mary Elizabeth Pope, aged forty-three.

William Pope said deceased was his wife. On Sunday, Oct. 22, she was in her usual health, but got ill towards night, and gradually worse until Wednesday, when he went to Mr. Morris, a chemist in Virginia row, and he came and saw deceased and gave her medicine. He charged three shillings, and promised to continue his visits for three shillings a week, saying that the wife was suffering from a severe attack of erysipelas. On Thursday morning the husband woke up at 6.30, and found her dead in bed. She had had four doses of the physic.

Mr. Phillips, divisional surgeon of police, made a *post-mortem* examination of the deceased and found the lungs the seat of extensive inflammation, and it extended to the heart. There was not the slightest trace of erysipelas. The chemist was not called in until Wednesday, it would have been impossible for him or any one else to have saved her.

The Coroner, in summing up, said that "Government ought to step in and stop the pernicious practice which exists whereby duly qualified doctors are cheated out of their fees; for if a chemist visits a patient and receives a fee he is liable to a fine of £20. A chemist is a very useful man in the sphere in which the Government directs he should move, but the law should be enforced in all cases where he oversteps the prescribed limit."

### The Female Medical Students.

At a meeting of the Senatus Academicus of the University of Edinburgh, the following letter addressed to the Secretary, was read:—"Craig-house, Lothian Burn, Friday, Oct. 27th, 1871.—Sir,—In the absence of the hon. secretary, I am desired by the Executive Committee for Securing a Complete Medical Education to Women in Edinburgh to inform you that they have passed the following resolution, in the hope that the removal at least of all pecuniary difficulties may facilitate the arrangements of the Senatus for completing the medical education of those ladies who have already matriculated in the University:—"That the Secretary be instructed to write to the Senatus, in view of their approaching meeting, to state that, in the event of special lecturers being appointed by the University to give qualifying instruction, to women, the Committee are willing to guarantee the payment to them of any sum that may be fixed by the Senatus for their remuneration, in case the fees of the

ladies are insufficient for that purpose, and that, if necessary, they are willing further to undertake to provide such rooms and accommodation as may be required for the delivery of the said lectures, if it should be found absolutely impossible for the University to provide space for that purpose.—I am, &c., KATHARINE BURTON." The Senatus, by a majority of 14 to 9, refused to adopt the proposal, as it was considered impracticable. Mrs. Thorpe, Miss Chaplin, and Miss Peachy have successfully passed their final professional examination.

**The Cooking of Ophthalmic Statistics.**

THE *Boston Medical and Surgical Journal* publishes in its issue of October 12th a communication made by Dr. Edward Loring, of New York, to the American Ophthalmological Society, which appears to us a very instructive contribution, not only in its scientific bearing, but from its exposition of the falsity of statistics which are made to order in favour of certain surgical proceedings. Dr. Loring selects for comparison the proportionate successes in the extraction of cataract by the old flap operation and by the fashionable modified linear method. He observes that in the 1,500 cases of flap extraction collected by Graefe in 1863, the successes were set down at 80 per cent., *the standard of success being taken at one-fourth*. In 1865 the same writer published a separate series of similar cases, in which the successes, by the same standard, were 84 per cent. of perfect results, and 11 per cent. of half success; and he then states that in his private practice the success of the old flap extraction produced a proportion of 91 per cent. of perfect cures. The peripheric linear method then became the rage, and it has since become the fashion to sneer at flap extraction, as if no surgeon who was not mad would think of removing a cataract without snipping off a bit of iris at the same time. Dr. Loring, however, points out that in the 300 cases published by Graefe (by no means, be it observed, so large an experience from which to judge) the success was put down at 90 per cent. But if it were, the standard of success was lowered from one-fourth to one-sixth, so that in reality, with this deduction of 9 per cent., the successful cases were only 81 per cent., so that it seems that, calculated by the same standard, Graefe's balance swings rather to the side of flap extraction. Dr. Loring accuses Dr. Knapp, who published with great admiration of the fashionable procedure, three sets of cases of 100 each, of making his calculations of success by a standard not of one-fourth, or even of one-sixth, but of one-tenth, and Dr. Loring says it strikes him as manifestly unjust and unscientific to maintain the superiority of one operation by statistics *in which the standard of excellence used is two and a half times less than the other*. And so say we. Before any sound surgeon ingests the laudations which a surgical inventor lavishes upon his *soi disant* improvement, he should take care that he knows what is meant by success. To our knowledge many a cataract extraction is called a success, when the patient is able to keep from falling down stairs.

**Stimulants in Workhouses.**

At the special committee of the West Derby Guardians appointed to inquire into the excessive use of stimulants in the workhouse of that union, the Chairman said they had spared no pains in endeavouring to arrive at the

facts in reference to which they had been appointed to report. He was sorry to say that the result of the investigation showed that the West Derby Union occupied a very unenviable position in regard to the consumption of stimulants. In the last year the West Derby Union was at the head of the other unions with regard to expenditure on stimulants, with one exception, being 7s. 3d. per head, while the death-rate—1 in 9—was also the highest. The natural inference was that it would have been better if the consumption of stimulants had not been so great. He hoped the guardians would co-operate in the endeavour to diminish the supply of beer and spirits to the poor of the union.

Dr. Costine said, unfortunately for that union, about 75 per cent. of the poor who were brought to the workhouse had been improvident, and were suffering from diseases arising from drunkenness, which materially assisted to propagate fever and other diseases. He did not know whether it was from any peculiarity of the locality, the air, or the beer, or the water, but it was a fact that three-fourths of the poorer classes were suffering from a thirsty madness for drink, and were in a chronic state of alcoholism, or charged with alcohol. That being the case, when a medical man came to treat them he found that an ordinary quantity of stimulants was not sufficient.

Mr. Lancaster thought it should be taken into consideration that the union had been suffering from one of the most severe epidemics which had been known for a long series of years. He noticed that in Toxteth Union the use of stimulants exceeded that in the West Derby Union, being 8s. 4d. per head last week.

Mr. J. Davies (West Derby) said Mr. Chambers had made a return, showing the consumption for the twelve months ending the 30th Sept. The admissions of sick persons had been 2,254, and the total amount spent on stimulants £880 15s. 2d., the cost of each case per head being 7s. 9½d. The average length of time each person had remained in the hospital was 3½ weeks, and the number of weekly cases in the house was 8,710, and the individual cost had been 2s. 0½d. per week, the per centage of deaths being 7 in 100. The total cost of beer consumed by the 21 officers of the house was £65 7s. 8½d. in the year, the average cost per week being 2s. 2¾d.; the average cost of stimulants for each officer being 1s. 2¼d. He thought such a return showed that the West Derby Union need not hide its head behind any other.

The report was adopted, and ordered to be circulated amongst the guardians and officers of the Union.

There was no other business of public interest.

Mr. Young, who is chief of the Bureau of Statistics of the United States Government, gives as an estimate of the sales of liquors in the United States during the fiscal year ending June 30th, 1871, the following:—

|   |                     |
|---|---------------------|
|   | Dols.               |
| Whiskey, 60,000,000 gals. at 6 dols. retail.....                            | 360,000,000         |
| Imported spirits, 2,500,000 gals. at 10 dols. retail                        | 25,000,000          |
| Imported wine, 10,700,000 gals. at 5 dols. retail                           | 53,500,000          |
| Ale, beer, and porter, 65,000,000 bbls. at 20 dols. retail.....             | 130,000,000         |
| Native brandies, wines and cordials, quantity unknown, estimated value..... | 31,500,000          |
| <b>Total.....</b>   | <b>6,00,000,000</b> |

Estimating the population at forty millions, the annual amount expended for intoxicating drinks by each man, woman and child of the population is fifteen dollars.

**Liberality!!**

At Bideford, a medical officer to the Local Board has been appointed; salary *ten guineas a year!*

**Medical Society of London.**

On Monday, November 13th, Dr. Carpenter, of Croydon, will show two very interesting cases of Locomotor Ataxy before this society.

**Dr. Dalrymple, M.P.**

DR. DALRYMPLE, M.P. for Bath, who went out to New York in August for the purpose of collecting information as to the treatment of habitual drunkards, has been suffering since his arrival from intermittent fever

**Old St. Thomas's Hospital.**

OLD St. Thomas's Hospital, or at least a considerable portion of it, has been taken by the London Pantechneion Company, and the wards are now to be devoted to the storage of carriages and furniture of all kinds. The company have obtained possession of what was known as the new wing of the hospital, which has been repainted and is ready to receive goods at once. The company have a sufficient extent of open spare ground to enlarge the premises very considerably as the requirements may demand; they include at present, besides the ordinary warehouses, fire-proof rooms and sale rooms.

**How to Collect Diatoms.**

THE *American Journal of Microscopy* recommends, as the best plan of collecting diatoms in large quantities, to tie a thin, fine piece of linen over the faucet of the hydrant in the evening, and allow a small stream of water to pass through it all night. In the morning take off the cloth and rinse it in a little water in a goblet. When ready to examine, take a drop of water from the bottom of the goblet with a small pipette, or glass rod, and place it on a flat slide, or a slide with a concave depression, holding a few drops. Then, with a power of 100 or 350, sweep the field, and you will be rewarded with the sight of a wondrous collection of beautiful and unique forms.

**Compressed Air in Hail.**

PROF. REINSCH, says the *Journal of the Franklin Institute*, mentions the curious fact that in some hail which he examined beneath the microscope, there was found at the centres of the stones a spherical globule, which proved to be air. When these globules were nearly freed by the melting of their icy confinements, they burst the last portion of the shell with energy, and, expanding, occupied in a bubble form a space more than fifty times greater than when confined; showing that they had been subject to a pressure equivalent to more than fifty atmospheres. Cold may possibly have had some part in this diminution of volume; but the temperature necessary to produce so great a reduction in volume must have reached 214° C. at the point where the hail was formed, if cold had been the only cause in play. Whatever explanation we assign to this interesting observation, it certainly must be regarded as the most unexpected one which has appeared in the study of this puzzling phenomenon. Prof. Reinsch recommends the diligent use of the microscope as the only means of solving the problem of the history of hail.

**Diploma Forgery in England.**

It would appear that a traffic in diplomas even more dishonest than the trade in degrees "in Absentia" is going on in England. The *British Medical Journal* gives a narrative of circumstances which have led to the discovery of the affair and illustrates the impossibility under English law of obtaining anything like protection for public life and limb. A stationer in Holborn was applied to to insert in a form of diploma the name of the person who handed it to him. The diploma was from New York and was duly attested by the names of the examiners and the college seal. The stationer, when the customer had departed, suspected that the parchment was not all right took it to the College of Surgeons where, on further inspection, it was ascertained that the names of the examiners were all forged by facsimile lithography. After unceasing efforts to arouse some action on the part of diplomatists and the law, Mr. Trimmer was at length obliged to get the document photographed as the only protection possible against the carrying out of the fraud.

**A Preservative for Surgical Instruments.**

MR. SPILLER, the eminent chemist, contributes to the *Photographic News* a paper on nickel-plating. He suggests the universal application of this process to all steel instruments and declares it is a perfect and lasting preservative against rust and corrosion. He caused a regulation sword to be so plated and has ascertained that it is perfectly secured against rusting in wet weather and easily kept in condition by simply wiping it with washleather. A small bar of steel similarly coated has been repeatedly immersed in water for hours together and even immersed for days without in the least tarnishing its surface. There is no direction in which this invention will be as applicable as to surgical instruments.

**The Hampstead Hospital Inquiry.**

WE have delayed any comments on this investigation until its conclusion. The inquiry being now over, we at once commence the publication of a critical review of the case, prepared expressly for this journal, and to which we particularly invite the attention of all interested in the matter.

This review is not a mere analysis of the evidence produced at the inquiry, nor is it founded upon the reports that have appeared in the daily papers. The writer of it was present throughout this protracted investigation, and we have no hesitation in expressing our belief that no journal was more ably represented than the MEDICAL PRESS AND CIRCULAR. To give a mere report of the proceedings would have been easy enough—had we had the space at our disposal. To present a *précis* of the whole, with the suggestions and comments of one qualified to pass a judgment, and who watched day by day the progress of the proceedings, is a very different thing. This, however, we have been able to compass, and we are sure that our readers will appreciate the skill and patience displayed by the author of the special review we commence to-day.

The Committee of Council of the British Medical Association have elected as secretary, out of nearly 200 candidates, Mr. Francis Fowke, House-Governor and Secretary of the Birmingham General Hospital.

THE Session of the Epidemiological Society opens this evening (Wednesday).

SIR H. SUMNER MAINE has taken his seat in the Senate of the University of London, as successor to the late Mr. Grote.

THE *Warrington Guardian* announces that Mr. James Hatton, of Hatton, has given £5,000 to the Warrington Dispensary.

SIR WM. FERGUSSON and Dr. Morell Mackenzie have been elected Corresponding Members of the Royal Buda-Pesth Society of Physicians.

MRS. THORNE, Miss Chaplin, and Miss Pechey were successful in passing their first or professional examination in Edinburgh last week.

THE Brown Institution will be opened next month, and comparative pathology will probably be largely studied in the new laboratories.

A "SOLLY MEMORIAL" has already made good progress, more than £300 having been subscribed in memory of that amiable surgeon. A scholarship and a bust are talked of.

THE last Hospital Sunday in Liverpool produced a collection amounting to £4,869 from 195 congregations, or about £25 for each. Of the gross sum £4,500 were distributed to the hospitals.

DR. MASSEY, C.B., head of the Sanitary Branch at Whitehall yard, will, it is said, embark for India early next year, and be succeeded in his present appointment by Dr. Muir, who will probably be the next Director-General of the Army Medical Department.

THE department of the Medical Director-General of the Navy is in a few days to be moved from Somerset House, to share with the Royal Marines Office the premises at No. 7 New street, Spring Gardens, thus making the twelfth distinct location in which the Admiralty departments are now assembled.

THE *London Mirror* records an altogether unprecedented list of bequests and donations to various charitable institutions in one single week. It comprises one of £1,400, 17 of £1,000 each, 5 of £500 each, 6 of £300 each, 4 of £250 each, 22 of £200 each, 5 of £150 each, 27 of £100 each, 23 of £50 each, and 4 of £25 each, besides several smaller sums, amounting in all to about £33,000.

It is reported on apparently good authority, that a much needed reform in fever hospital administration is shortly to take place. In each fever hospital a certain number of private wards are to be set apart for the reception of patients from the well-to-do portion of the community. When an infectious disease attacks one member of a family it seldom ends there, but frequently overtakes others under the same roof. If the report be correct the adoption of the plan will have a good effect in more ways than one, and we therefore hail it with satisfaction.

ON Thursday last, a man, suffering from concussion of the brain, was taken to King's College Hospital where his wound was dressed. Upon application he was refused admission as an in-patient by the then house-surgeon, Mr. Roche, and was carried away by those who had picked him up after his fall, in a very dangerous state. He soon after died, and at the inquest Mr. Roche's conduct was severely censured by the coroner and jury, and in the absence of this gentleman who was reported to have left the hospital, the enquiry was adjourned, in order to compel his attendance to offer explanations.

## SCOTLAND.

### GENERAL COUNCIL OF THE UNIVERSITY OF EDINBURGH.

THE statutory half-yearly meeting was full of interest to the medical profession.

The Principal, Sir A. Grant, presided.

Dr. Alexander Lindsay was elected assessor.

The Council were urged to expedite their movements to improve the graduation in law.

The subject of the influence of the General Council was considered, and the committee on entrance examination was re-appointed.

#### GRADUATION IN ARTS.

PROFESSOR MASSON gave in this report, which stated that "the committee, in the absence of any information of what has been done by the University Court in consequence of the representation of the General Council at its meeting in April, have no further recommendation to make at present on the subject of improved regulations for graduation in arts; in view, however, of the expected deliverance of the Court, also because there may be further data on this subject from other quarters, they advise the reappointment of the committee, with the same powers, and instructions to report to next meeting of the General Council." In supporting the motion, Professor Masson said there was no deliverance on the subject by the University Court. He thought it was to be regretted that during six months there should have been an absolute ignorance on the part of those indirectly concerned of what the Court had done in consequence of the Council's previous representation, or whether they had done anything. Had it been possible for the Court to have come earlier to some resolutions on the subject, and these had formed part of the newspaper reports, then it would have been perfectly possible to consider them, and to have come to this meeting with some definite observations either in correction or agreement, and so this great question, which, since he came to be connected with the University, had been bandied to and fro. If the Court had made a communication on the subject, the solution of this great question would have made some progress between their last meeting and the present. As it was, they were where they were before; while, if the Court had done otherwise, the question whether there was to be a broadening of the basis of their graduation, and the bringing in of great studies hitherto kept out, would have been a little nearer solution. He concluded by moving as follows:—"That the report be approved of, and the committee reappointed accordingly; and that the last communication from the University Court on the subject be referred to the committee as part of the matter for their next report." Professor Calderwood seconded the motion; which was agreed to.

#### THE MEDICAL EDUCATION OF WOMEN.

DR. ALEXANDER WOOD submitted the following resolution:—"That, in the opinion of this Council, the University authorities have, by published resolutions, induced women to commence the study of medicine at the University; that these women, having prosecuted their studies to a certain length, are prevented from completing them from want of adequate provision being made for their instruction; that this Council, without again pronouncing any opinion on the advisability of women studying medicine, do represent to the University Court that, after what the Senatus and Court have already done, they are at least bound in honour and justice to render it possible for those women who have already commenced their

studies to complete them." I should like, in speaking to this motion, to commence by clearing myself from any supposition that may be entertained in regard to the exact position which I occupy in regard to it. I am not here as an advocate of women's rights, whatever private opinions I may hold upon the subject. I am not here to argue the question as to whether it is a right and proper thing that women should study medicine, whatever opinion I may hold upon that; still less am I here to argue the question whether we should have mixed classes of males and females to study medicine, whatever opinion I may hold in regard to it. These matters have all been settled and settled by the constituted authorities of the University. With these, therefore, we have nothing to do. I do not approach the question as the champion of these females at all. I approach the question from the other side altogether, as a member of this University Council—as one who has been long interested in the prosperity of this University—as one who deeply deprecates the most unfortunate position in which the University has placed itself. (Cheers.) I do think that for the sake of our *Alma Mater* we should now do all that is in our power to extricate it from the false position which it has taken up—a position so false that at every step it takes into the matter it seems to fall into inextricable blunders. Dr. Wood then quoted the calendar as the official guide to show that women had been, as it were, invited, and regulations laid down for their instruction. He then said: Here is a plain invitation to women to present themselves at the University of Edinburgh to enter the medical classes of the University of Edinburgh for the purpose of studying medicine. That this was generally and universally understood is plain and evident from the fact that the whole press of the country was full of the question; and the University of Edinburgh reaped praise in many quarters, and blame in a few, for what was called the liberal step she had adopted. I am not here to say whether that step was a right one or a liberal one, or anything about it at all. It may have been very good—it may have been very bad; but the step was taken, and it would be insulting the wisdom which decorates that platform, if I supposed it was taken without full deliberation, without a full knowledge of the consequences which it entailed upon the University. (Cheers.) I cannot suppose that such a step would be taken without the advice of my distinguished friend the medical Nestor of the University, whose voice on all medical questions influences the University so much, Dr. Christison. I cannot suppose that the step would be taken without the advice of the other medical professors, who had at all events a voice in the several courts. But what I argue is this, that, having duly deliberated and put the question through all the processes which the University Act demands, the University did see it to be their duty—did see it advantageous to them—to open the classes to women. (Applause.) I will be told, I have no doubt—for we are told strange things in this discussion—that while the classes were opened, there was not a word said about examination. Well, there is an ingenious instrument which I have sometimes seen with a door at one end which lets an animal in, and has a bar at the other which does not let the animal out, so that as soon as he has got in by the door it shuts. That is called a trap. I have no notion that dignified professors, or that the University Court, would set a trap to catch women, but most certainly a trap was set—most certainly a trap was baited against certain innocent, simple women, who were betrayed to go in; and most certainly when they got in and got half-way through they found the door shut in front of them—the excellent Principal without authority of any man, so far as I can make out, shutting the door behind them. Well, this is our position, and I seriously ask whether this is a dignified and right position for the University? (Hear.) Look at what it compelled them to do. The other day the Medical Faculty—a body scarcely recognised at all—took upon them to set all these regulations aside, and put my unfortunate friend, Dr. Balfour, into a position in which, to get out of the fangs of the law, he had to rescind the one day the intimation the Medical Faculty compelled him to make the previous one. I do not think it can be argued with any strength of argument that the fact of the examination not having been mentioned is proof that examination was not intended. We have the opinion of the Lord Advocate and Mr. Fraser that it implied they were to be allowed to go to examination. There is no provision made by which the professors can be compelled to teach women. I think if professors entertain the strong views we had from Professors Turner and Liston, at one of our meetings, in regard to the impropriety of teaching women, that it would be an improper thing to compel them to do so. But it

remained with the University authorities to deal with the recusant professors. If they had not made arrangements by which every professor was to receive women for the purpose of educating them, they should have adopted the alternative of providing for the education of women. I say they did a wrong thing—they did a rash thing—and brought the University into a false position. You may shut the doors of your University Court—you may prevent anything transpiring as to what takes place in your *Senatus*; but you will not prevent the public from becoming aware of the wrong you are doing to these women, and very deeply sympathising with that wrong. I have in my possession at this moment what I don't intend to present to the Council, but it was sent to me this morning—a petition which is signed by upwards of nine thousand females in Scotland. The petition is a short one; but because I think technical objection may be taken to its presentation, I will only read the words of it:—“*To the General Council of the University of Edinburgh.*—Gentlemen,—It being often said that women have no desire for the medical services of their own sex, and take no interest in the struggle for professional education in which some women are now engaged, we, the undersigned, desire to record our emphatic protest against these statements, and to express our earnest hope that it may soon be possible for those of us who desire it to consult thoroughly educated physicians of our own sex. We venture further to thank you, and the University of which you are members, for the foremost part which Edinburgh has already taken in providing for the instruction of women in medicine; and to entreat you to carry forward your good work and complete it, by making such regulations and arrangements as shall afford to women the means of obtaining a complete medical education, and the usual medical degree at the hands of your time-honoured University.” The feeling which has been engendered against this University by the treatment of these women is certainly very strong. Whatever may be the law on the question, I say, according to every moral consideration, that you are bound to give to these women what you promised them when you admitted them. I do think that, morally, you are bound to give them a full and complete education, and even to take in the examination for finding them fit to pass as doctors of medicine. It may be a wrong thing; I may not wish to see women doctors of medicine—I do not say whether I do or not; the responsibility of that does not rest with me, but with the University authorities, who have begun, and have not the courage apparently, nor the talent, to see how it is to be continued. (“Hear, hear,” and hisses.) If that is to be the case, the sooner they confess their error—the sooner they make compensation to those who have spent their time and money in consequence of that the better. But it must be done in a legal way; not by some illegal motion instructing their servant to refuse admission to what this Council and the University Court have given admission—not by the fiat of the Principal forbidding women to become matriculated students of the University, although there is law and authority for them doing so. Under these circumstances, then, what I ask this Council to do is, without committing itself in the slightest degree to the general question of the medical education of women, without committing itself in the slightest degree to the way as to which the difficulty is to be solved, to urge on the University Court and *Senatus* to carry out what they have begun.

PROFESSOR TURNER, in moving an amendment to Dr. Wood's motion, said that in the course of last summer the question came before the *Senatus Academicus* with reference to whether the ladies who had been admitted to study in the University would be qualified to present themselves for examination, should they desire to do so; and, on the motion of one of my colleagues, a memorial was prepared and transmitted to eminent counsel for the purpose of obtaining their opinion as to whether the University should admit women to examination in medicine. This memorial was prepared by the law agent of the University, instructed by the Deans of the Faculties of Law and Medicine. Care was taken that the memorial should be a fair memorial—without presenting the view of one party or the other—that it should be a fair and accurate statement of the fact. Counsel in reply stated as follows:—“It may be that the *Senatus* or other authorities can give permission to the professors of the University to teach persons not legally entitled to demand admission as students; but we do not think that persons who have attended lectures by virtue of such permission have, even when permitted to matriculate, any right to claim the position or privileges of students. We are of opinion that the *Senatus* have not power to admit to exami-

nation for a degree persons who, though they may have attended the course of lectures necessary to graduation, were not, in our estimation entitled to the legal status of students of the University." (Applause.) Now, in the month of October this year, the Medical Faculty were informed that certain ladies wished to present themselves for the preliminary examination and others for the first professional examination. The Medical Faculty had a meeting, and with this opinion of counsel staring them in the face the Faculty came to the decision "that it was not prudent to admit them for examination until the Senatus had fully considered the matter in connection with the opinion given by counsel; and that in case the Senatus decided in favour of the candidates, a special examination should be provided at the earliest possible date." (Applause.) It just suspended the examination till the Senatus had sanctioned it. The term "interdict" was unfortunately employed by the Dean, but the Faculty never instructed him to interdict anybody. It was simply an unfortunate expression of his own, which had been commented upon to the prejudice of the Faculty. Such is the position the Medical Faculty has taken in connection with this matter; and I trust this simple statement of facts will be looked upon by the Council as one which absolves the Faculty from the charge of abrogating a statute of the University. It is moved by Dr. Wood:—"That in the opinion of this Council the University authorities have, by published resolutions, induced women to commence the study of medicine at the University." Now, did the University authorities "induce" women to enter the University? To find out that we must look a little further back than Dr. Wood did. Professor Turner has cited a letter dated March, 1869, from Miss Jex Blake, who wrote:—"As I understand that the Statutes of the University of Edinburgh do not in any way prohibit the admission of women, and as the Universities of Paris and Zurich have already been thrown open to them, I venture earnestly to request from you and the other gentlemen of the Medical Faculty permission to attend the lectures in your medical school during the ensuing session. I beg to signify to you my willingness to accept any such conditions, or agree to any such reservations, as may seem desirable to you; and, indeed, to withdraw my application altogether if, after due and sufficient trial, it should be found impracticable to grant me a continuance of the favour which I now request." Now, you will observe that this lady comes forward, and she asks to be allowed to attend our lectures, and she expresses her willingness, in case any difficulty should arise—and she obviously thought it might arise—to withdraw. That went before the Medical Faculty, which gave not an absolute acceptance but a modified one. The resolution of the Faculty was that she "should be allowed to attend the summer classes of botany and natural history as a student of medicine, by way of experiment; and that in the event of her attendance interfering in any way with the discipline of the classes, the privilege should be withdrawn; that the consideration of her request to attend other medical classes should be postponed until the Faculty have seen the result of the experiment." That was the reply of the Faculty to the first application. The Medical Faculty consists of twelve persons. Six were present and one dissented, so that the resolution was adopted by a minority of the Faculty.

DR. WOOD: Not a minority.

PROFESSOR TURNER: A minority of five out of twelve. We must look to the regulations of the Court; and I ask any one who considers these regulations to say whether the University is bound to complete their education? I see nothing that binds them to do it. I see only this, that there is a permission to study medicine if the professors in the Faculty of Medicine will instruct them. It is a permissive measure altogether. I beg to move the following amendment:—"That the subject to which the motion of Dr. Alexander Wood refers being at present duly under consideration of the proper authorities of the University, the General Council decline to interfere in the matter at present, being confident that the cases of the several ladies who have commenced their medical education will be considered with all favour compatible with the Universities Act, the University Statutes, and the University Charters."

PROFESSOR WYVILLE THOMPSON seconded the amendment.

PROFESSOR CHRISTIE said: It was not my intention to take any part in the discussion, but Dr. Wood has referred to me, and I wish to put him right. Dr. Wood stated that the proceedings of the Senatus Academicus and the University Court were not taken without the advice of the most venerable of the professors. Of course I must take the imputation that I am venerable, although I have no sensation of being vener-

able; and except in regard to one peculiar quality which is venerated, that of white hairs, I don't think there is any very great difference between myself and Dr. Wood. But I did give advice. My advice was this, that the Faculty and the Senatus were running on very dangerous ground; that they did not know what they were to commit themselves to; and that they had better pause and consider well before they took any step. Dr. Wood has talked of a trap. Who made that trap and who laid it? Not the opponents of the ladies. It was their friends who laid that trap. We had nothing to do with it. We opposed the intention of the ladies to get into that trap—"hear," and applause)—and we opposed it in this way, and showed there was no disposition on our part to deceive the ladies at all, because when these resolutions were first passed by the Senatus, and forwarded to the University Court, I stated, and another member, whose opinion on that matter was of far greater consequence than mine—our Professor of Scots Law—stated that that decision did not decide the question of graduation. It decided that they were to be admitted to the classes to be instructed, but not to graduation, and the Professor challenged the friends of the ladies to bring up that question, but they did not do it. Therefore that question still remains undecided to the present day. I do not consider that the regulations agreed to by the University Court finally settle the question of graduation. Well, I am prepared, nevertheless, to accept of this amendment—viz., that the case of these ladies be considered. No doubt the University has been brought into a difficulty, but it has been brought into that difficulty not by those who opposed the wishes of the ladies, but by those who have been barking them and putting them forward. They are those who brought the University into a difficulty, but there is no doubt that these ladies have been brought into a difficulty too, and if we can get them out of it, I for one shall be glad to assist in getting them out. But how is that to be done? That is another question. There is one very obvious way in which it may be done. It is a way which many of our male students follow—that is, by going to other universities, which it is either more convenient to attend, or which they prefer to attend on account of the eminence of particular professors. Our students are a very migratory set; very few are educated entirely at our own universities. Many go abroad—some to Paris or the universities of America, and some to the universities of Germany, and there is nothing whatever to prevent these ladies going to these universities. They have already finished all the university education they require for going forward for examination, and there is no difficulty in them taking the remainder of their education abroad if they cannot get it in this country. If strangers go to one university, it will cost them very little trouble to exchange it for another. It would have been a difficulty for Edinburgh ladies staying here being asked to go abroad, and they would have pleaded that it was a great hardship to send them to a foreign university. But those ladies are strangers here, and they will not be more strangers where they go. (Laughter.) That is one way by which they can get out of the trap. But we know that the way pointed out in this motion, although it says nothing, refers to an innovation in the constitution of this University entirely new; because, look at it in any way you please, the real way in which you must look at it in the end is that it cannot be done without appointing new professors. Assistants you may call them, but they are substantially professors. Now I ask you is a proposition of this kind to be entertained—a proposition to extend the extra academical privilege, that of twelve subjects of medical study four may be taken with extra academical lectures? One of the propositions of Miss Blake is that this be extended to a greater variety of subjects; and it will require to be a question of a great variety of subjects indeed; because of the professors in the Medical Faculty I don't believe there is one, or more than one, at all events, who will be ready to give a separate course of lectures to the ladies. I believe that those professors who made the experiment in the winter are not likely to make it again—(laughter)—and, at all events, those who have not made it will not try it; and therefore the whole education will be given outside the University. Is that an innovation you would like to be exercised? Don't take a leap in the dark. Don't agree to a motion until you see what the consequence is to be.

DR. PITCH said: I wish the Council to know what I regret was not communicated through the newspapers, but what would have been communicated if the newspaper reporters had been present during the recent meeting. There was presented to the University authorities a decided legal opinion by two of

the most eminent counsel at the Scottish bar, that what the University authorities proposed to do with reference to women was contrary to statute, and that what the University Court and the Senatus had approved of was inconsistent with law; and that being the case, I ask this Council if it was not reasonable for the University authorities, for whose conduct in the matter I am in no degree responsible, to pause before they went forward in the course which had been pronounced by the highest legal authorities to be contrary to law.

PROFESSOR CALDERWOOD said that while it is true that a legal opinion was given that what had been done by the Senatus and by the Court—composed to a great extent of eminent lawyers—was illegal, it was also a fact that there was laid on the table of the Senatus an opinion from counsel stating that it was legal. Then Dr. Phin describes the opinion as having been got from the highest legal counsel. All I can say is, that there is an opinion in favour of it from a still higher counsel; and if there be anything higher than the highest, then we have got a little higher opinion than the highest in favour of the legality.

Dr. Alexander Wood replied, and the House then divided.

The result of the vote was as follows:—

|  |     |
|--|-----|
| For Dr. Wood's motion . . . . .            | 97  |
| For Professor Turner's amendment . . . . . | 107 |
| Majority for Professor Turner's amendment  | —10 |

THE opening lecture of the Edinburgh Medical School was delivered by Mr. Annandale. In consequence of the resignation of Dr. Gillespie, Mr. Annandale will in future devote himself to clinical teaching, Dr. John Chine, assistant-surgeon Royal Infirmary, succeeding him as lecturer on Systematic Surgery. Dr. Watson and Dr. Joseph Bell will also lecture clinically.

### SANITARY PRINCIPLES OF SCHOOL CONSTRUCTION.

Now that new school boards are preparing for the construction of new school-rooms, it is of importance they should be apprised of the sanitary defects that require amendment in the greater proportion of those existing for the elementary schools in this country. Mr. Edwin Chadwick, C.B., has, in a communication to the *Journal of the Society of Arts*, undertaken this service. He considers that the chief sanitary defects of these schools are—(1) Defective ventilation; (2) Defective warming; (3) Bad drainage and foul latrines; (4) Want of means of maintaining personal cleanliness; (5) Bad lighting; (6) Bad arrangements of desks and seats; (7) Want of proper means of gymnastic exercises; (8) Insufficient and ill-paved play-grounds. He would submit that it is important that school boards should require, in the competition for plans, that these evils should be first specially considered and provided for, and that the architectural designs and elevations be made of secondary consideration.

It is painful to observe the condition of children in the common schools in winter time, going there in cold and wet, in driving sleet and snow, frequently ill-shod, and commonly ill-clothed—kept in the school during excessively long hours under any conditions for children, with feet and hands painfully cold—fingers often so benumbed as to be scarcely able to hold their slates and pencils; the open fires at one end of the school not freely to be approached, and when approached, the warming or heating on one side, “roasting in front and freezing behind,” so as to give inflammations or colds from the disturbed and unequal circulation. The confinement of children for five or six hours in such conditions, overtaken mentally, and painfully constrained bodily, are surely evil conditions requiring active intervention for their relief.

Mr. Chadwick considers that of the modes of warming, those by hot-water pipes and iron surfaces are of inferior, and sometimes, when for high heats, are of pernicious effect, and are very expensive. Besides, they are apt to warm only the sides of the rooms, or the upper parts of them, and to leave the

feet cold, unless an inconvenient and objectionable degree of heat is created over the whole room. It is, moreover, matter of considerable experience that warming by earthenware surfaces, or stone surfaces, especially by heat diffused over wide earthenware, or concrete surfaces, is more agreeable and more salubrious than any warming by iron surfaces. Mr. Chadwick has long advocated the principle of floor warming.

Next to the foul air from overcrowding—from the breath—there is the foulness arising from a congregation of dirty skins, as well as of dirty clothes. Medical officers, who have to do the work of vaccination with children of the lower and middle class, are aware how small is the proportion of them who are ever properly washed, and how painful, and at times how dangerous, is the duty of operating upon numbers of them consecutively in confined rooms. The economical fact should be inculcated that a pig that is regularly washed puts on a fifth more flesh, and that flesh of a better quality, than the pig that is unwashed; and that the same rule holds good with washed, as against unwashed children. Five washed children may be sustained on the food requisite for four that are unwashed, to bring them up in the same condition. Besides, the washing itself is preventive of infections and contagions, such as the itch and other diseases.

In the large children's institutions, where children are boarded, the effects of progressive sanitary improvement have been distinctly marked. In one, where the death-rate had been about twelve per thousand, the foul air from cesspools and bad drains was excluded, the latrines were mended, and the ventilation was improved, when the death-rate was reduced to eight in a thousand. Next, regular tepid ablution, and, in summer time, cold water bathing, and careful skin-cleanliness was introduced, and the death-rate was reduced to four in a thousand.

To deal with these cases, there is, in well-appointed schools in Holland, usually a female attendant on the schoolmistress, some old woman, who takes the dirtied children into an apartment and washes them, the schoolmistress herself being of an occupation of a quality above such service.

On such experience it is to be insisted upon that every elementary school should be provided with a retiring room or closet, with warm water, with the proper appliances for the cleansing of children. It is a provision of a very high order of importance for the infant schools of the lower districts.

The common play-grounds for children are either the natural soil, which is very dirty, or a gravel, which is sharp and wasteful in the excessive wear of shoes and clothes; children fall down upon it and seriously bruise or lacerate themselves, and the sharp grit gets into their eyes or the lungs. A Val de Travers' asphalted paving would, with its peculiar elasticity of feel at the surface, serve much better, especially for gymnasia. Where very good smooth paving of the quality in question is laid down, Mr. Chadwick does not see the necessity of children, or at least those of the poorest class, kept in public institutions, wearing either shoes or stockings in dry, summer weather. If the feet be regularly washed and kept clean, he questions whether they would not be better bare at such times.

As the efficiency and economy of teaching requires the children to be gathered from wider areas than heretofore, often from considerable distances, it will often be necessary to make provision of food for them. In the great middle-class school of the City of London, it has been found requisite to provide cheap dinners for those boys who do not bring their food with them, in what the Rev. Mr. Rogers, the governor, calls their “nose bags.” In the great metropolitan Jews' school, which provides for 1,700 children of the poorest class of Jews, its leading supporters, the Baron Lionel de Rothschild and the Baroness, of their own munificent educational grants, have been accustomed to bestow on that one school £800 per annum,

to provide a portion of bread and some milk for the very destitute and necessitous children, to enable them to attend.

On this subject Mr. Edward Tuffnell observes—"In many schools the children bring their dinners, usually miserable enough, and eat them between twelve and one, when there is an interval of school. Now, I think every school should have a small cooking apparatus, in which some girls should be taught to cook cheapsoups, stews, &c., and then the children, girls, at least, should be kept in school, and given dinners so cooked, which might be done, as I have ascertained, at a penny a head, the parents paying."

There is yet a very frequent and serious defect in the constructions of the common schools, which requires to be guarded against, namely, the bad distribution of light. From a paper by Dr. Varrentrapp, of Frankfort, it appears that from the insufficiency of light, and from the bad distribution of light, in the schools of Germany, nearly a third of those who remain in them during and beyond the secondary stages, are subject to short-sightedness. A great deal of distortions and curved spines are, as Dr. Varrentrapp shows, occasioned by the wrong adjustment of seats, a topic which, as well as others of the wall-colourings and school-fittings, is beside Mr. Chadwick's immediate purpose, who considers that schools ought to have more of window space, of windows made with double or with very thick glass, which is economical, as saving heat, and is, moreover, advantageous, as lessening the transmission of sound from the streets.

## SPECIAL CORRESPONDENCE.

### THE MEDICAL CONGRESS AT ROME.

(FROM OUR SPECIAL CORRESPONDENT.)

ROME, 25th October, 1871.

I have great pleasure in sending you a brief account of the Medical Congress here for your ably conducted journal. We have had a great success—so great that it is not easy to say in a few words how successful we have been.

The great questions that have occupied us have been:—

1. The cultivation of rice. This must be restricted, and a knowledge of the subject should form a part of the education of all practitioners in the provinces.
2. The measures for preventing the spread of venereal diseases—such as the increase of hospitals for syphilis, and adding to the number of inspectors.
3. University organisation. We have confided to a commission of medical men from different parts of the Peninsula this question, including the proposal to transform the theoretical chairs into experimental and practical professorships, and also that of extending the curriculum over six years.
4. Fees. We have condemned the plan of a legal tariff, as we desire to leave every practitioner free to fix the fee which he thinks fit for his services.

The discussion on all these points was very interesting, and is sure to lead to good results.

A very important decision has also been adopted on the proposition of Dr. E. Rey, one of the delegates at the Congress. It is to the effect that at the next congress, which is to be held two years hence, a discussion shall take place as to how we can proceed to establish true liberty of instruction and obtain the benefit of free competition in medical education. Several other questions have also been proposed for discussion at the next congress which is to be held at Bologna. Among these I may mention another brought forward by the same distinguished delegate, Dr. Rey. It will interest your readers and your well known liberal views will receive it with fair consideration. It is this—considering the actual scientific

and commercial relations of various nations, whether it is not time to admit the universality of the diploma of doctor, and establish a true international authority to practise our profession. Particularly since the Convention of Geneva it becomes clear that there are contradictions in the laws that prevail in different countries and in questions of science it is time to reconcile them. Nations that have adhered to the Geneva Convention may perhaps carry their relations a step further towards international fraternity.

The Congress was honoured by the presence of Virchow, who was received with acclamation and enthusiasm. Everyone here knows that the illustrious author of "Cellular Pathology" was the first to propose to his government to recognise the Kingdom of Italy in 1862, and we all appreciate him most completely.

Adieu, my honoured colleague. I shall have great pleasure in penning a few lines from time to time for your English readers from this city.

## IRISH COUNTY INFIRMARIES.

The *Tyrawley Herald* says:—At the last Assizes, the Grand Jury passed a resolution, recommending that any future appointments to offices in county infirmaries should be made contingent on the retention of those institutions—conveying the opinion of that body, that the work of the county infirmaries was done, and that their days were drawing to a close. At the ensuing Assizes, the Grand Jury ought to add to the resolution already passed, one calling on the Government to issue a commission of inquiry into management, expenses, and results so far as these infirmaries are concerned, with a view to test their practical efficiency, and their superiority or otherwise to the workhouse infirmaries, which are claimed rather than they to be the true helpers of the sick poor of the country. Such a resolution would follow naturally and properly the one on record, and would hasten the solution, so anxiously desired by many of the best friends of our suffering humanity, of the question as between the respective institutions. The expense of both upon the tax-paying community is felt to be very grievous, and it is insisted on every hand that one should yield to the other. Let the question then be fairly tested—which does the work, or which is best calculated to do it? It will admit of easy decision, and no time, in our opinion, should be lost in deciding it.

The view which the *Tyrawley Herald* in identifying the function of the County Infirmary and the Union Workhouse is not new, but it is totally fallacious. There is really no such identity, and it would be as reasonable that the necessity for a Blind Asylum or Incurable Hospital should be judged by the efficiency of a general Surgical Hospital, as to attempt to pass a verdict on the County Infirmaries by comparison with Union Workhouses. Everyone knows that a very considerable portion of the medical constituency of a county is in the small farming class, who are in independent, but struggling circumstances. Such persons do not, as a rule, take dispensary tickets, but they pay a small sum for the doctor when they are sick. But when their illness becomes one of life and death, which would require hospital treatment, or involve an operation, it would be very unfair to put them to the alternative of becoming paupers and going into a pauper hospital where their companions would be destitute persons supported by the rates, or on the other hand, of paying to a doctor such remuneration as would be necessary for a long attendance. For such persons the County Infirmaries are provided, and if such institutions did not exist, the petty farming class would be

compelled to remain in their own houses badly nursed and insufficiently attended to.

The very feeling prevents such persons from becoming paupers, whether we call it pride or self-respect, and is by all means to be encouraged and certainly ought not to be regarded as a mere matter of sentiment which is not worth setting against a money saving.

## Literature.

### THE ANNUAL ORATION DELIVERED BEFORE THE MEDICAL SOCIETY OF LONDON, 1871.\*

"THE work of the Medical Society of London in the Advancement of Therapeutics and the Science of Medicine" is the subject of Dr. Cholmeley's eloquent discourse, which we should like to see in the hands of not only the Fellows of the Medical Society of London, before whom it was delivered, but also in the hands of the entire Profession, on account of the information it conveys as to the doings of our medical fathers from a century past to the present time, and their opinions on subjects that even now keep in a state of active fermentation the medical mind—Vaccination—Electricity—Transfusion of Venous blood—Bronchotomy—Venesection—The Hygiene of Public Institutions, Towns, &c. In verity, Dr. Cholmeley has engrasped within the space of thirty-five pages of carefully-composed letterpress the rarest gems of medical literature that have been submitted to us for some time, and, diverse as are the subjects treated, the reader will be agreeably surprised to find in this Oration, instead of a limping, unconnected literary essay, a golden chain of medical facts, cohesively united, eloquently rendered, trite, pithy, and masterly.

## Correspondence.

### INNOCENT ADULTERATIONS AND THEIR RESPONSIBILITIES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the last number of the MEDICAL PRESS AND CIRCULAR, there is an article on "Innocent Adulterations and their Responsibilities," which commences thus:—"It is a satisfaction to observe that Dr. Lethely's view that adulteration is not a fraud, or to be tolerated as long as the adulteration is not noxious to health, is repudiated by a body of traders, amongst whom it has been the general impression that adulteration is rife. We have heard a good deal about effervescent citrate of magnesia made up with tartaric acid and washing soda, and such practices have been defended in high pharmaceutical places as innocent and unavoidable. Our view has always been that the buyer ought, in common honesty, to have what he pays for. Let him pay for, and have a mixture of mustard, bath-brick, and turmeric, instead of real mustard; or of sugar, potato starch, and cocoa, instead of real cocoa." Now, although it is difficult to arrive at the exact meaning of the author, through the maze of bad grammar, and exaggeration which pervade the sentence, yet I presume he intended to say that in my view innocent adulteration is not a fraud, and may be tolerated as long as it is noxious to health. Permit me to state that to a certain extent, this is my opinion, but not altogether, for even such adulterations are described by me as fraudulent when practised on the public without their knowledge and sanction. If the writer of the article, in question, will trouble himself to read the report of my paper on "Legislative Measures for Preventing the Adulteration of Food, Drink, and Drugs," in the "Sessional Proceedings of

the National Association for the Promotion of Social Science," for Thursday, March 9th, 1871, he will find that I have clearly described two kinds of adulterations, namely, innocent and noxious; the former being, in my opinion, fraudulent, when practised on the public without their knowledge and consent, and the latter always criminal. As regards the former, which is generally the result of that kind of competition in trade which the public encourage, and from which, in the end, the public derive advantage, where is the harm provided the adulteration is innocent, and the public have full knowledge of it? What good reason, in fact, is there, why we should prevent the dealer from increasing the bulk of an article, or improving its appearance, or adding to its flavour, providing he does it without injury to the nutritive quality, the dietetical uses, or the wholesome nature of the substance. All that is required to guard against fraud in such cases is, that the dealer should sell the article for what it really is, and should specify by means of a distinct label what the mixture is composed of, and the proportions of the several constituents. If he failed to do this, and sold a mixture of things for a genuine article, he should be liable to penalty for fraudulent dealing; and with these safeguards, I would let the manufacturer employ whatever materials he likes to cheapen or improve his wares, provided always that the materials are harmless. It must be otherwise, however, with the use of mineral, poisonous, or unwholesome compounds—the addition of alum to bread, of mineral pigments to confectionery, or, indeed, of any mineral substance to food, as well as the use of unsound or decayed articles of diet should be regarded as adulterations of a serious nature, and should be strictly prohibited." These are my views of the subject, as set forth in the paper referred to, and, in reality, they do not seem to differ substantially from those of the writer of your article; for he is clearly of opinion that the dealer should be at liberty to satisfy the demands of the public, and that the buyer should be at liberty to purchase either the genuine or the adulterated article,—that which he condemns, as I do, is fraudulent dealing.

I remain, yours, &c.,

HENRY LETHELY.

17 Sussex place, Regent's park.  
Nov. 4, 1871.

## OBITUARY.

### THE LATE DR. EVANSON.

RICHARD TOWSON EVANSON, the genial poet of the Profession, has passed away in the seventy-second year of his age. Well does the writer remember his last interview with the gentleman and physician, who through life has secured the affection of so many of his fellow men. In his youth he had been a Professor in Dublin. Among his colleagues were Jacob, Marsh, Stokes, Beatty, and others, whose names are household words. Maunsell and Evanson on "Diseases of Children" was for many years without a rival as a Manual; and, notwithstanding the many works since published on the subject, may be studied with profit even now. That written in conjunction with his friend Dr. Maunsell, was Dr. Evanson's most important medical work, but he contributed to this Journal a number of valuable papers. Three years ago he collected his poems into a handsome volume, under the title of "Nature and Art."

### THE LATE LANGSTON PARKER.

For many years the late Mr. Langston Parker has been regarded as an eminent syphilographer. He too has died at a ripe old age, sixty-seven, having been born in 1803, at Birmingham, where his life has been passed. He was from the first connected with Queen's College, and held the Chair of Anatomy, and the Surgeoncy to the Hospital for many years. His chief work was the "Modern Treatment of Syphilitic Diseases," which has reached a fifth edition; but he was also the author of many papers on this and other subjects. Indeed, he was interested in subjects outside his profession, and *au courant* with all that passed in medicine, science, and general literature.

\* "The Annual Oration delivered before the Medical Society of London, 1871." By Wm. Cholmeley, M.D., F.R.C.P., Physician to the Great Northern Hospital, and to the Margaret street Infirmary for Consumption and Diseases of the Chest. London: J. and A. Churchill.

**THE LEGAL RESPONSIBILITY OF MEDICAL CHARITY.**

THE profession in Ireland has been much exercised in the consideration of the relations of medicine to the prosecution now under trial in Dublin, and the novelty of the position in which surgery has been placed by the line of defence adopted, cannot fail to produce decisions and discussions which will yet turn to profitable account, by defining more accurately the relations of hospital surgeons to criminal law, and the moral position of medical witnesses. It has never, as far as we know, occurred before that the entire burthen of the defence has fallen upon the medical evidence, and, in this case, it has not so fallen from any real flaw in the medical testimony, which should tempt the defending counsel to select it as the weakest point, but rather because there seems to have been no shred of a defence on any other ground, and thus it was necessary desperately to contest a disputed point which, in the construction of a strong case, would have been of little or no importance.

But the decision of the Lord Chief Baron in favour of the admission of expert medical evidence is of great importance, because it lays open to legal attack, the competency of medical men which the law had already recognised, through the medium of the Medical Register. In other words, the official certificate of competence which the law had conferred was set aside, and the defending counsel was allowed abundant latitude in raising the question as to whether a registered practitioner was, or was not, up to the proper educational standard. Henceforth, no medical witness can give his opinion in the witness box as a recognised authority, but must be prepared to see his opinion stand or fall by other evidence produced in contradiction. The arguments on this point were of such importance as to justify their republication here:—

The Solicitor-General said: It is not competent for my learned friend to go into what the opinion of other medical men might be. That is the very thing Judge (afterwards Chief-Justice) Erle says would be objectionable; for he says to admit the evidence would be to raise a collateral issue in every case as to the degree of skill a medical man possesses. The question will arise, not what was the animosity of the man who fired the shot, not what was the natural result of that wound, not was a crime committed, but what was the amount of the skill of Dr. A., and whether Drs. B., C., and D. had more skill and experience, training and education; whether Dr. A. used his skill as rival doctors would approve, they alleging that if another mode of treatment was adopted the man would have lived. It would be a most dangerous doctrine to lay down, and I think the wiser course would be to prevent any such collateral question being raised. I submit the only question here is that the jury must be satisfied,—First, did the prisoner fire the shot, what was the intent with which he fired, and was the shot dangerous to life?

Mr. Butt submitted that the evidence should be received. Lord Hale said: "If a man gives another a stroke which it may be was not in itself mortal, but with good care he might be recovered, yet, if he dies of the wound within a year and a day, it is homicide, or murder, as the case is. But if a man receives a wound or hurt that is not mortal, but with the ill applications of those about him of unwholesome salves or medicine, the party dies, if it can clearly appear that the medicine, and not the wound, was the cause of his death, it seems it is not homicide, but this must be made to appear clearly and certainly to be so." He (Mr. Butt) intended to bring the case within the principle so laid down by Lord Hale. He would give evidence that Talbot's wound was not mortal; that it was the ill application of Dr. Stokes that made it so; it would be made clear that it was the operation, not the wound, was the cause of death, and, therefore, there was no homicide.

Serjeant Armstrong (for the Crown) contended at great

length against the admissibility of any such evidence. The law, he should contend, ran thus: If a man of malice aforethought inflicted a dangerous wound, he is answerable for the death which may ensue, though that death be immediately caused by the treatment of a fit and competent surgeon, acting on that treatment in good faith and to the best of his skill and knowledge. The settled law of the land and the law of common sense was, that when a man wilfully wounded another he was responsible for all the consequences of his act and of his victim's death, even if the death arose from the mistake of a competent, honest practitioner treating him *bonâ fide*.

The Chief Baron gave judgment, which was in effect that evidence could not be received to show whether the operation was injudicious or not, but that evidence could be taken as to whether the operation was skilfully or unskilfully performed.

The Lord Chief-Justice thought that evidence could not be taken either as to the judiciousness of the operation or the skilfulness of the *modus operandi*, but as when two judges differ the law leaned in favour of the prisoner, the Lord Chief Baron should rule the case.

It is, of course, not our place to express an opinion at present, as to whether or not Dr. Stokes' treatment of the case was skilful and judicious, but, so far as the case has gone up to the moment when we write, the profession has, we think, no cause for shame either of its surgery or its testimony in the witness box. Dr. Stokes' demeanour there and the nature of his evidence throughout the terrible ordeal to which he was subjected, was in the highest degree honourable to him and to his profession. With gentleman-like frankness and an evident readiness to tell the truth—the whole truth and nothing but the truth, he combined lucidity in his explanations and a manifest intimacy with the surgical and anatomical points which were the subject of his examination, and he retired from the witness box, leaving behind him the assurance that whether in this case his treatment was judicious or the reverse, he possesses in a high degree the qualities of a good surgeon and an honourable man.

We have yet to hear what is to be said in support of the theory of malpraxis in the case. No doubt a case will be made, but it must evolve new and startling disclosures if it succeed in removing the impression created by the Crown medical witnesses. The gentlemen who have the courage voluntarily to enter the witness box to prove the impropriety of the treatment have submitted themselves to much unfavourable criticism in the Profession. With the censure involved in that criticism we have only a certain degree of sympathy. If any of the medical witnesses for the defence introduced themselves unsolicited into the case for the purpose of throwing discredit on their professional brother, or, if they availed themselves in doing so, of information acquired in confidential consultation, there can be no second opinion that their conduct is unworthy of imitation; but we cannot see that a medical man called upon for his opinion, on a given point, should hesitate to give full and faithful expression to it, because it might happen to be adverse to a member of his own profession.

We are distinctly of opinion that reticence under such circumstances is an honourable quality, and we hope that when such emergencies arise, it will not be open to the public to say that personal pique or professional jealousy, or even political bias, have been served at the expense of our character for good fellowship and *esprit de corps*.

THE first meeting of the thirty-fourth annual session of the Dublin Obstetrical Society will be held on Saturday evening, the 18th inst., in the hall of the College of Physicians, at eight o'clock, when Dr. Kidd, President for the past session, will deliver an address; and an election of officers for the ensuing session will be held. The Council have invited a number of visitors. The Council recommend that Dr. Kidd be re-elected president, and that Dr. J. A. Byrne and Dr. Sibthorpe be elected vice-presidents. They also recommend that Dr. Halahan be re-elected treasurer, and that Dr. Athill be re-elected secretary.

**Tubercular Leprosy.**

At the last meeting of the Ulster Medical Society Dr. H. S. Purdon, physician to the Belfast Hospital for Skin Diseases, exhibited a patient suffering from the tubercular form of leprosy. He had resided for some years in the East, where malarial diseases were common. At the time of coming under Dr. Purdon's care, the lobes of ears, face and wrists were distinctly tuberculated. Skin thickened, and hard over posterior part of both legs, aloe of nose ulcerated; tongue fissured; voice husky; skin of face, hands, arms and legs of a purplish brown colour; complete anaesthesia of arms, and only partial of feet. He had tried different plans of treatment without any benefit. Dr. Purdon prescribed carbolic acid, commencing with four drops thrice daily, and gradually increased. The anaesthesia was slightly improved in the lower extremities, and hardness of skin less; faradization was suggested to stimulate the atrophied muscles of arms.

**NOTICES TO CORRESPONDENTS.**

**THE DYTE APPEAL FUND.**

To the Editor of "The Medical Press and Circular."

DEAR SIR,—In addition to the £12 already announced in your columns as received for the "Dyte, v. the St. Paneras Guardian's Appeal Fund," I have to acknowledge, with best thanks, the following subscriptions. In doing so, however, permit me to mention that, unless further help be speedily forthcoming, Dr. Dyte will be liable to lose some hundreds in the prosecution of his just claims, admitted as such by the Guardians themselves:—

|                            | £  | s. | d. |

Oct. 31, 1871.

**THE SOCIETY FOR THE WIDOWS AND ORPHANS OF MEDICAL MEN.**

To the Editor of "The Medical Press and Circular."

SIR,—Who is the Secretary of this Society, and what is his name and address?  
Yours, in confidence, D. H.

[The Secretary is Mr. J. B. Blackett. The offices of the Society are at 53 Berners street, London, W. We can assure our correspondent that it is a most excellent charity, deserving the support of every member of the profession.—Ed. M. P. & C.]

To the Editor of "The Medical Press and Circular."

SIR,—Will you kindly state in next issue, in whose gift do the Appointments of Physicians to Lunatic Asylums lie?

Subscribers.  
[In the gift of the Lord-Lieutenant.—Ed. M. P. & C.]

Dr. R. E.—We are very much obliged, and will write to you soon. We will send to you the things that you want. We shall be very pleased to see, and in the meantime will do all you propose.

E. R.—We will have the journal sent to the new address, but are not sure that it is correctly deciphered. In case of error, please send it again, legibly written.

AGENT.—Please send us the proper address in full.

**VACANCIES.**

- Hospital for Women, Soho square, London. Assistant-Physician.
- Victoria Hospital for Sick Children, Chelsea. House-Surgeon.
- Hampstead Small-pox Hospital. Assistant Medical Officer. Salary 12 guineas per month, with board and lodging.
- Paddington Parish, Middlesex. Medical Officer. Salary £120, exclusive of fees.
- Wandsworth Union, Surrey. Medical Officer. Salary £250 per annum.
- Liverpool Infirmary for Children. House-Surgeon. Salary £80 per annum.

- Infirmary for Consumption, Margaret street, London. Visiting Physician.
- Royal Infirmary, Edinburgh. General Superintendent. Salary £450.
- Kent Hospital, Canterbury. House-Surgeon. Salary £80 per annum.
- Royal College of Surgeons, Ireland. Assistant Librarian. Salary £100 (See advt.)

**APPOINTMENTS.**

- KENNEDY, D. M., M.D., Visiting Medical Officer to the Kirkdale Hospital, Liverpool.
- MARK, Joseph, M.D., L.R.C.P., L.R.C.S.Ed., Resident Surgeon to the Belfast Union Hospital, vice Dr. Core, resigned.
- MARRIOTT, C. W., M.R.C.S.E., Surgeon to the Warneford Hospital.
- SAUNDRY, J. B., L.R.C.P.L., Resident Medical Officer to the Royal Kent Dispensary, Greenwich.
- WATSON, Patrick Heron, M.D., F.R.C.S., Senior Acting Surgeon, and Lecturer on Clinical Surgery at the Royal Infirmary, Edinburgh.

**MEETINGS OF THE LONDON SOCIETIES.**

- WEDNESDAY, Nov. 8.—HUNTERIAN SOCIETY.—7½ P.M. Council Meeting.—8 P.M. Mr. Bryant, "On Insuperable Constipation and its Treatment."
- EPIDEMIOLOGICAL SOCIETY.—8 P.M. Opening Meeting of the Session.—Address by the President, Inspector-General Lawson.
- Friday, Nov. 10.—CLINICAL SOCIETY OF LONDON.—8½ P.M. Dr. John Murray, "On a Case of Paracentesis Thoracis."—Dr. Anstie: The continuation of a Case previously reported.—Mr. Christopher Heath, "On a Case of Wound of the Uterine during Ovariectomy, with Recovery."—Dr. Ogle: "Notes on the Temperature in Tetanus."
- Monday, Nov. 13.—MEDICAL SOCIETY, 8 P.M. Ordinary Meeting.
- Tuesday, Nov. 14.—ROYAL MEDICO-CHIRURGICAL at 8 P.M. Ordinary Meeting.

**OPERATION DAYS AT THE LONDON HOSPITALS.**

- WEDNESDAY, NOV. 8.
- MIDDLESEX HOSPITAL.—Operations, 1 P.M.
- ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M.
- ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M.
- ST. THOMAS'S HOSPITAL.—Operations, 2 P.M.
- ST. MARY'S HOSPITAL.—Operations, 1½ P.M.
- KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
- GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
- UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.
- ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
- LONDON HOSPITAL.—Operations, 2 P.M.
- CANCER HOSPITAL.—Operations, 3 P.M.
- THURSDAY, NOV. 9.
- ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
- ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M.
- UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.
- ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.
- CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
- WEST LONDON HOSPITAL.—Operations, 2 P.M.
- FRIDAY, NOV. 10.
- ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M.
- ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
- CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
- SATURDAY, NOV. 11.
- HOSPITAL FOR WOMEN, Soho square.—Operations, 9½ P.M.
- ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M.
- ROYAL FREE HOSPITAL.—Operations, 2 P.M.
- ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M.
- KING'S COLLEGE HOSPITAL.—Operations, 1½ P.M.
- CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
- MONDAY, NOV. 13.
- ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M.
- ST. MARK'S HOSPITAL.—Operations, 2 P.M.
- METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
- TUESDAY, NOV. 14.
- ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M.
- GUY'S HOSPITAL.—Operations, 1½ P.M.
- WESTMINSTER HOSPITAL.—Operations, 2 P.M.
- NATIONAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.
- ROYAL FREE HOSPITAL.—Operations, 2 P.M.

**Marriages.**

- DOERSON—BOURNE.—On the 24th ult., at the Parish Church, Edgbaston, Thomson Dolson, of Windermere, to Marianne, youngest daughter of the late Henry Bourne, Esq., of the Limes, Edgbaston.
- HALL—DE LEONAL.—On the 24th ult., at the Parish Church, Bolton, John Hall, M.D., of Raddington, Notts, to Margaret Louise, daughter of the late J. Baptiste P. Chappe de Leonal, of Prestwich, Lancs.
- STEVENS—WINTER.—On the 25th ult., at Pewsey, Wm. Edward Stevens, L.R.C.P.Ed., M.R.C.S., to Eliza, daughter of George Winter, Esq.

**Deaths.**

- ABERCROMBIE.—On the 1st ult., at Cape Town, James Abercrombie, M.D., L.R.C.P., Edin.
- BOWEN.—On the 23rd ult., D. Bowen, M.R.C.S.E., of Newport, aged 32.
- COOKE.—On the 19th ult., F. Cooke, M.R.C.S.E., of Ashton, aged 60.
- EVANSON.—On the 26th ult., R. T. Evanson, M.D., of Torquay, aged 71.
- HILDER.—On the 29th ult., H. H. Hilder, M.R.C.S.E., of Great Berkhamstead, Herts, aged 68.
- LOWDELL.—On the 18th ult., G. Lowdell, F.R.C.S.E., of Brighton, aged 58.
- MOORE.—On the 28th ult., (after suffering for a long time from locomotor ataxy), W. D. Moore, M.D., of Fitzwilliam square, Dublin, aged 58.
- SIMPSON.—On the 24th ult., Edwin Simpson, M.R.C.S., L.S.A., of Long Melford, Suffolk, aged 49.

Established 1848.

## PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY LL.D. M.R.C.S., F.L.S., &amp;c., (KING'S COLL.), and Author of VIA MEDICA,

Has always upon his books a large number of desirable investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &amp;c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for negotiation (in addition to those advertised in Dr. Langley's List, (which is sent post free on application).

**Y 330. DEATH VACANCY.** Dr. Langley has been honoured with instructions to negotiate for the succession to the PRACTICE of the late Mr. Langston Parkes, F.R.C.S., of Birmingham, just deceased. The practice was partly special, with a good family connection, and realised about £1,300 a year. The copyright of valuable works may be included in the purchase, and would afford a fine scope for a specialist in the same department. A very efficient introduction can be given to the private practice, and liberal terms would be conceded to a suitable gentleman. Applications in the first instance, to be addressed to Dr. Langley, as above.

**Y 331. FOREIGN APPOINTMENT with Private PRACTICE.** The succession to a valuable Appointment in the East, is open for negotiation upon easy terms. Salary £400 a year, with the right of private practice, which is estimated to be worth £1,000 a year, in the hands of an active gentleman, the life is pleasant, and the expenses, including horses, servants, &c., need not exceed £300 a year. The Country is beautiful, and the locality healthy.

**Y 332.** In the suburbs of a LARGE TOWN, a non-dispensing practice, realising £550 a year, and capable of great extension. Midwifery fees, £1 ls. and upwards; visits, 3s., 5s., and 7s. 6d. The locality is pretty; the air, clear and bracing; the house is very conveniently situate, with large garden, stabling, &c. Rent, £35. A thorough introduction can be given by partnership or otherwise, and easy terms of payment could be arranged, but no gentleman without £250 at present command, can be communicated with.

**Y 329. ASYLUM.** The resident medical proprietor of a large asylum in a Western County, desires to meet with a gentleman to join him as partner, with option of succession. The mansion stands in its own grounds within sight of the sea, and is within three minutes' of a railway station, and within half an hour's drive of an important junction, affording communication to all parts of the Kingdom. The asylum has been established about thirty years, and is licensed for about 150 patients, male and female. About 100 are at present resident. The rent of the whole, without buildings, &c., is £245. The furniture may be taken at a valuation at the end of the partnership. No gentleman can be communicated with, unless he can give a satisfactory reference as to the capital at his command.

**Y 327. HOME COUNTIES.** An old-established practice in a SMALL TOWN, about 130 miles from London, realising £470 a year, but capable of considerable increase. Patients are chiefly good middle class; very little opposition. About seventy midwifery cases a year. Easily worked appointments produce £150 a year. The house contains every convenience, with garden, meadow, &c., on very beneficial lease; three-fourths of the rental being paid by the produce of the ground. An efficient introduction can be guaranteed.

**Y 323.** Excellent opportunity for a Surgeon with small capital. NUCLEUS of unopposed PRACTICE for transfer, present income, £350 a year. Part of the premium may be paid by instalments.

## The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

|                             |        |
|-----------------------------|--------|
| Seven lines and under ..... | £0 4 0 |
| Per line afterwards .....   | 0 0 6  |
| One quarter page .....      | 1 5 0  |
| Half-page .....             | 2 10 0 |
| One do. ....                | 5 0 0  |

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

**TO MEDICAL MEN.**—To be LET, at HARROW, a Residence in a good locality, where a first class practice can be secured. Apply to B. C., care of C. MITCHELL and Co., 12 and 13 Red Lion court, Fleet street, London.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—The Council of the College will, at the Meeting to be held on Thursday, the 16th inst., proceed to elect a properly qualified person to act as Assistant Librarian, at a salary of £100 per annum.

Sealed applications, accompanied by testimonials, directed to the Library Committee, to be forwarded to the Registrar of the College, on or before one o'clock, on Monday, the 13th. The person appointed, will be required to give security.

By order,

JOHN BRENNEN, Registrar.

COOKESTOWN HOUSE, INSTITUTED FOR

## THE MEDICAL TREATMENT OF THE INSANE OF BOTH SEXES.

This highly respectable Mansion in no respect resembles, either internally or externally, what is usually known as an Asylum.

The Demesne, Conservatories, Graperies, and Grounds are unusually extensive, and in good condition.

There are Billiard Tables for both sexes, with indoor and outdoor amusements, including Vehicles.

Cookestown House is within three miles of Carrick-on-Suir Station, with a like distance from Fiddown, both on the Waterford and Limerick Lines, and in connection with the G. S. & W. and Kilkenny Lines.

For terms, and Form of Admission, apply to the Resident Physician.

JOHN PEPPARD, M.D., &amp;c.

Cookestown House, Piltown, co. Kilkenny.

## ROTUNDO LYING-IN HOSPITAL, DUBLIN.

Consulting Physician—Alfred Hudson, M.D., F.K.Q.C.P.I.

Consulting Surgeon—Robert Adams, M.D., F.R.C.S.I.

Master—George Johnston, M.D., F.K. Q.C.P., &amp;c.

Assistant Physicians—Alex. Taylor, L.K.Q.C.P., &amp;c. J. J. Cranny, L.K.Q.C.P., &amp;c.

This Hospital, the largest Chartered Clinical School of Midwifery in the British Dominions, contains wards for the treatment of diseases of females, in addition to the wards (10 in number) appropriated to lying-in-cases.

A large Dispensary for the diseases peculiar to women is connected with the Hospital.

An Obstetrical Museum, containing upwards of Five Hundred Preparations, and a Library, are attached to the Hospital.

Clinical Instruction in Midwifery, and the Diseases of Women and Infants, is given daily.

The Pupils are privileged to attend the Cow-pock Institution, Sackville street and York street.

The Lectures are recognised by the Royal College of Surgeons in Ireland, London, and Edinburgh; the King and Queen's College of Physicians; the Apothecaries' Hall of Dublin and of London; the Army and Navy Medical Boards; and all the other Licensing Bodies.

The Diploma from this Hospital is recognised by the Poor-law Commissioners as a qualification in Midwifery for all Hospitals and Dispensaries under their control in Ireland.

Accommodation is provided for a limited number of Intern pupils.

Two Courses of Lectures are given yearly—the First commencing early in November, the Second early in May, but pupils can enter at any time.

TERMS OF ATTENDANCE:—Intern Pupils.—For Six Months, £21; for Three Months, £12 12s.; for Two Months, £8 8s.

Extern Pupils.—For Six Months, £10 10s.; for Three Months, £6 6s.; for Two Months, £4 4s.

No Pupil is entitled to the Diploma under a period of Six Months' attendance.

Applications to be made to the Master or Secretary, at the Hospital, Rutland Square,

rabed; a throttling sound is heard in the trachea, and foam mingled with blood rests upon the lips. This blood is derived from the tongue and lips, which are generally cut by the teeth during the clonic spasmodic stage. The fit lasts one minute, two minutes, or three minutes; very rarely longer. This estimation of the time may seem to such of you as have witnessed an attack of epilepsy as understated; but the time has been carefully observed in a large number of cases by Calmeil, Trousseau, and others. The horrible nature of the spectacle no doubt causes it to appear longer than it really is. When the attack is terminated, the sufferer remains in a state of hebetude, exhausted, almost comatose. These events recur from time to time at irregular intervals. Such, in brief, is an epileptic fit.

This is the "grand mal" of the French; but, as has been mentioned, there is a milder form of the disease, the "petit mal," or epileptic vertigo. In this, if there is any convulsion, it is very slight, and may pass unnoticed. There is commonly a transient pallor of the face, but no succeeding suffusion. The tongue is not bitten. No foam is seen on the lips. Consciousness and the mental functions are suddenly put in abeyance. The person affected fixes a steadfast gaze, or rolls his eyes, totters a little, and the attack is presently over. He resumes his conversation or reading; he continues his work, aware that something, he knows not what, has occurred. He feels as though awaked from a distressing dream. There is an infinite variety in this form of the malady. A child, in the midst of his play, stops, slowly turns his head to the right side, and gazes with wide open eyes. There is not the slightest spasm of the facial muscles, and insensibility is at the same time so great that a needle passed through his flesh is unfelt. In five seconds the child regains consciousness, but appears astonished and out of humour. In a quarter of a minute more the affair is terminated, and the child resumes his play. I am indebted for this and the following examples to the classical work of the late Mr. Trousseau. A child, whose mother and grandmother were healthy, but whose aunt and great-aunt were epileptic, utters a plaintive cry, and places her hand over the pit of her stomach, turning her head slowly to one side. She gazes fixedly, and at the same time makes grimaces. A minute is not passed, when the patient rises with a stupefied appearance, reels and sometimes falls. At first she cannot speak at all; then gives utterance to some inarticulate sounds. After five minutes the attack is terminated, and she speaks distinctly. Her own account of her sensations is that she feels at first an acute pain at the pit of the stomach; that almost immediately this pain gains the tongue, and becomes extremely intense; that she then loses consciousness during one or two minutes, and when she begins to come to herself again, she finds that she cannot speak because of a painful paralysis of the tongue, which disappears gradually.

A person subject to epileptic vertigo is playing cards. He holds one ready to throw upon the table. He suddenly rests motionless, his eyes fixed or shut; he heaves a deep sigh and plays his card, consciousness having returned.

An ecclesiastic, whilst performing the ceremonies of his church or preaching, suddenly commences to make grimaces, and to sing or speak in a strange, or incoherent manner. A musician, playing with others in an orchestra, suddenly ceases to see or to hear those around him, but he yet continues to perform his part. These last examples are of great interest, as showing that during the attack the epileptic may, with a degree of regularity, perform some acts automatically. It further sometimes happens that during the fit the epileptic may assault and do grievous harm to some of those present; this tendency to commit acts of violence being a peculiar phase of the disease.

A gentleman of literary pursuits, standing conversing with a friend, suddenly stops short in the midst of a sentence, gazes

wildly around him; then, without warning, falls with fury upon his companion, striking repeated blows with his stick, and truly endeavouring to kill him. A minute passes. He is surprised to find himself struggling, being utterly unconscious of what had occurred. Some of you may recollect a patient in the wards of Mercers' Hospital who, when the fit was almost passed, was accustomed to strike at anyone who happened to be near him. These cases are interesting in a medico-legal point of view, since an epileptic, in company with a single person, might kill him, and morally be innocent of crime, conscious of no evil till he waked horror-struck to find the deed done, when possibly his fears might lead him to conceal the corpse. The character of epileptic delirium is essentially impulsive, and instantaneous in its access; indeed, this rapidity of its invasion, unpreceded by any symptoms, serves to distinguish it from other forms of mania. But I cannot now pursue this branch of the subject.

When detailing the phenomena of a true epileptic fit, the "grand mal," it was stated that it attacked with extreme suddenness. It very frequently happens, however, that there is a premonitory symptom. I allude to the well-known "aura epileptica." This sensation is variously likened to a breeze or a vapour, which, starting from some part of the body or extremities, rises to the head, and the fit at once begins. Sensations of creeping, warmth, or numbness take the place of the aura in many. A shooting pain is the aura in other cases. Sometimes the premonitory symptom is not a sensation, but a convulsion or paralytic attack in one of the extremities, yet to these the generic name "aura" is equally applied, so that we have two distinct classes of "auræ," the "sensory" and the "motor." Among the sensory we class those curious phenomena connected with the organs of special sense, such as sparks of fire and various colours before the eyes; humming, or reports of rifles or cannons, in the ears; odours pleasant or the reverse in the nose, and strange tastes in the mouth. Troubles of the digestive organs, such as borborigmi, eructations, cramps in the stomach, serve as premonitions. Sneezing, yawning, stammering, cramps in the limbs, have also been observed.

Hallucinations replace the aura in some cases. A woman dressed in a red cloak, with a crutch, walks into a room, strikes the sufferer on the head, and he immediately falls down in a fit. A black dog rushes against another, and these phantasms are of regular recurrence in each case before the access of the fit. Quite analogous to these are the mental states, which precede and are the sole precursors of the attack in some. Hoarseness, irritability, quarrelling, or unusual gaiety; in fact, an entire change of disposition and character preceding by some hours the access of the disease.

The aura frequently has its starting place in one of the fingers, more especially in the thumb. The finger thus affected has been observed to grow red and to swell. The ring on the finger, for example, becoming unbearably tight, showing a determination of blood to the part. Strange enough, too, it has been found in some cases that a ligature tied around the point of origin, as it were isolating it, has sufficed to ward off the threatened attack. This may succeed for a few times; but then the attack will manifest itself with doubled or quadrupled force, so that many epileptics who have made trial of the ligature, refuse to resort to it. On the other hand, it must be stated that there are by no means few cases of epilepsy in which the ligature has proved an effective preventive of the threatened attack, and indeed permanent cure has resulted from section of the nerves leading to the part. When the starting point of the aura has been in an isolated portion of the integuments, destruction of the skin by *potassa fusa* has cured the disease. But you cannot predicate with certainty that the disease is peripheral in its character when capable of being arrested by ligatures on a limb. In a celebrated case detailed by Odier, in which cramps in the little finger of the

right hand commenced the seizure, and in which ligatures to the arm and fore-arm arrested the progress of events, after death an enormous tumour was found in the left side of the brain. When the aura assumes the form of spasms or cramps in a limb, forcible extension of the member has often an effect similar to that of ligatures in other cases. By many the aura is regarded as the first convulsion of the fit. That no aura precedes the attack in many persons subject to the falling sickness forms no conclusive reason, in the opinion of M. Brown-Séquard, for denying that the aura epileptica exists in these persons. For, he remarks, the aura may pass through nerve fibres which are not sensory, or the occurrence of the aura and the fit may be simultaneous, and that hence the aura is not perceived. As the aura passes up the arm, this member often becomes stiff or affected with convulsions, and extremely painful. An old cicatrix is occasionally the starting point of the aura, which almost invariably, no matter where it starts from, seeks directly the brain, the convulsions commencing when this goal is reached. However, it happens rarely that the aura, having originated in the body or head, passes down a limb—or, still more rarely, passes downwards and, then returning—attains the head. The aura is found more frequently in connexion with the *grand* than the *petit mal*, and according to the late M. Trousseau may be itself the sole manifestation of epilepsy.

The cry of the epileptic is a peculiar sound, striking with terror not only mankind, but even the brute creation. Animals flee away affrighted at the sound, and a parrot has been known to fall from his perch, and you will hear by-and-by it is a frequent exciting cause of the disease in others. It is caused by spasms of the laryngeal and contraction of the expiratory muscles.

(To be continued.)

## ORIGIN OF SPECIES:

PART OF A LECTURE INTRODUCTORY TO THE COURSE OF  
NATURAL HISTORY,

DELIVERED IN THE

UNIVERSITY OF EDINBURGH,

BY PROFESSOR WYVILLE THOMSON.

MY distinguished predecessor, the late Professor Edward Forbes, appears to have been the first who undertook the systematic study of marine zoology with special reference to the distribution of marine animals in space and in time. After making himself well acquainted with the fauna of the British seas to the depth of about 200 fathoms by dredging, and by enlisting the entire co-operation of many friends, among whom we find MacAndrew, Bailee, Gwyn Jeffreys, William Thomson, and many others entering enthusiastically into the new field of natural history enquiry, in the year 1841, Forbes joined Captain Graves, who was at that time in command of the Mediterranean survey as naturalist. During about eighteen months he studied with the utmost care the conditions of the Ægean and its shore, and conducted upwards of 100 dredging operations at depths varying from 1 to 130 fathoms. In 1843, he communicated to the Cork meeting of the British Association an elaborate report on the mollusca and radiata of the Ægean Sea and on their distribution as bearing on geology. Three years later, in 1846, he published, in the first volume of the "Memoirs of the Geological Survey of Great Britain," a most valuable memoir upon the connection between the existing Fauna and Flora of the British isles and the geological changes which have affected their area, especially during the epoch of the northern drift. In the year 1859 appeared the "Natural History of the European Seas," by the late Professor Edward Forbes, edited and continued by Robert Godwin-

Austin. In the first 100 pages of this book Forbes gives a general outline of some of the more important of his views with regard to the distribution of marine forms. The remainder of the book is a continuation by his friend Mr. Godwin-Austin, for before it was finished, an early death had cut short the career of the most accomplished and original naturalist of his time. I will give a brief sketch of the general result to which Forbes was led by his labours, and I shall have to point out that although we are now inclined to look somewhat differently on certain very fundamental points, and although recent investigations with better appliances and more extended experience have invalidated many of his conclusions, to Forbes is due the credit of having been the first to treat these questions in a broad philosophical sense, and to point out that the only means of acquiring a true knowledge of the *rationale* of the distribution of our present fauna is to make ourselves acquainted with its history, to connect the present with the past. This is the direction that must be taken by future enquiry:—Forbes as a pioneer in this line of research was scarcely in a position to appreciate the full value of his work. Every year adds enormously to our stock of data, and every new fact indicates more and more clearly the brilliant results which are to be obtained by following his methods, and by emulating his enthusiasm and his indefatigable industry. Forbes believed implicitly, along with nearly all the leading naturalists of his time, in the immutability of species. He says:—"Every true species presents in its individuals certain features, specific characters, which distinguish it from every other species; as if the Creator had set an exclusive mark or seal on each type."

He likewise believed in specific centres of distribution. He held that all the individuals comprising a species had descended from a simple progenitor, or from two, according as the sexes might be united or distinct, and that consequently the idea of a species involved the idea of the relationship in all the individuals of common descent; and the converse, that there could be no possibility be community of descent except in living beings which possessed the same specific characters. He supposed that the original individual or pair was created at a particular spot where the conditions were suitable for its existence and propagation, and that the species extended and migrated from that spot on all sides over an area of greater or less extent until it met with some natural barrier in the shape of unsuitable conditions. No specific form could have more than a single centre of distribution. If its area appeared to be broken up, a patch not in connection with the original centre of distribution, occurring in some distant locality, it was accounted for by the formation, through some geological change, after the first spread of the species, of a barrier which cut off part of its career, or by some accidental transport to a place where the conditions were sufficiently similar to those of its original *habitat* to enable it to become naturalised. No species once exterminated was ever recreated, so that in those few cases in which we find a species abundant at one period over an area, absent over the same area for a time, and recurring at a later period, it must be accounted for by a change in the conditions of the area which forced the emigration of the species, and a subsequent further change which permitted its return. Forbes defined and advocated what he called the law of "representation." He found that in all parts of the world, however far removed, and however completely separated by natural barriers, where the conditions of life are similar, species, and groups of species, occur, which, although not identical, resemble one another very closely; and he found that this similarity existed likewise between groups of fossil remains and between groups of fossils and groups of recent forms. Admitting the constancy of specific characters, these resemblances could not be accounted for by community of descent, and he thus arrived at the generalisation that in localities placed under similar circumstances, similar though specifically distinct, specific forms were created. These he regarded as mutually representative species. Our acceptance of the doctrines of "specific centres" and of "re-

presentation," or at all events the form in which we may be inclined to accept them, depends greatly upon the acceptance or rejection of the fundamental dogma of the immutability of species; and on this point there has been a very great change of opinion within the last ten or twelve years—a change certainly due to the remarkable ability and candour with which the question has been discussed by Mr. Darwin and Mr. Wallace. I do not think that I am speaking too strongly when I say that there is now scarcely a single competent general naturalist who is not prepared to accept some form of the doctrine of evolution. There are no doubt very great difficulties in the minds of many of us in conceiving that, commencing from the simplest living thing, the present state of things in the organic world has been produced solely by the combined action of "atavism," the tendency of offspring to resemble their parents closely, and "variation," the tendency of offspring to differ individually from their parents within very narrow limits; and many are inclined to believe that some law, as yet undiscovered, other than the "survival of the fittest," must regulate the existing marvellous system of the extreme and yet harmonious modification. Still, it must be admitted that variation is a *vera causa* probably capable within a limited period, under favourable circumstances, of converting one species into what, according to our present ideas, we should be forced to recognise as a different species; and such being the case, it is perhaps conceivable that during the lapse of a period of time—still infinitely shorter than eternity—variation may have produced the entire result. The individuals composing a species have a definite range of variation strictly limited by the circumstances under which the group of individuals is placed. Except in man and domesticated animals, in which it is artificially increased, this individual variation is usually so slight as to be unappreciable except to a practised eye; and any extreme variation which passes the natural limit in any direction clashes in some way with surrounding circumstances and is dangerous to the life of the individual. The normal or graphic line, or line of safety, of the species, lies midway between the extremes of variation. If in any period in the history of a species, the conditions of life of a group of individuals of the species are gradually altered with the gradual change of circumstances, the limit of variation is contracted in one direction and relaxed in another; it becomes more dangerous to diverge towards one side, and more desirable to diverge towards the other, and the position of the lines limiting variation is altered. The normal line, the line along which the specific characters are most strongly marked, is consequently slightly deflected, some characters being more strongly expressed at the expense of others. This deflection, carried on for ages in the same direction, must eventually carry the divergence of the varying race far beyond any limits within which we are in the habit of admitting identity of species. But the process must be, so to speak, infinitely slow. It is difficult to attach any idea to ten, fifty, or a hundred millions of years; or of the relation which such periods bear to changes taking place in the organic world. We must remember, however, that the rocks of the Silurian system, overlaid by ten miles thickness of sediment, entombing a hundred successive faunæ, each as rich and varied as that of the present day, are themselves teeming with fossils representing all the existing classes of animals except perhaps the very highest. If it is possible to imagine that the marvellous manifestation of Eternal Power and Wisdom involved in living nature can have been worked through the law of descent with modification alone, we shall certainly require from the physicists the very longest row of acyphers which they can afford. Now, although the admission of a doctrine of evolution must affect greatly our conception of the origin and *rationale* of so-called specific centres, it does not practically affect the question of their existence, or of the laws regulating the distribution of species from these centres by migration, by transport, by ocean currents, by elevations or depressions of the land, or by any other causes at work under existing circumstances.

So far as practical naturalists are concerned species are permanent within their narrow limits of variation, and it would introduce an element of infinite confusion and error if we were to regard them in any other light. The origin of species by descent with modification is as yet only a hypothesis. During the whole period of recorded human observation not one single instance of the change of one species into another has been detected; and, singular to say, in successive geological formations, although new species are constantly appearing, and there is abundant evidence of progressive change, no single case has as yet been observed of one species passing through a series of unappreciable modification into another.

## Hospital Reports.

### ST. GEORGE'S HOSPITAL.

#### *Smallpox and Vaccination.*

We have already given the details of all the cases of smallpox in the late outbreak. An analysis of them shows that out of the whole number recorded by Dr. Jones (27), as stated in the *MEDICAL PRESS*, 6 died, 4 in and 2 out of the hospital. Of these, 3 had other serious organic disease to contend with. 21 cases had been vaccinated; 7 had good marks; 14 indifferent ones. Of the 7 with good marks, 6 cases were very slight. Dr. Jones followed up diligently the inquiry as to how the infection was introduced, and in the new volume of the hospital reports his investigations are detailed at length. He was led to think that the disease might, having been introduced, be propagated through the laundry, as he noticed a correspondence between the changing days of linen and the days of supposed infection.

He states the matter thus:—

Case 1. Saw a friend suffering from smallpox on Nov. 10.

The sheets of case 1, in which the patient had slept one or two nights, were sent to the wash without undergoing disinfection on Nov. 24.

The same sheets returned and placed on the beds on Dec. 1.

Sheets of Case 2 were sent to the laundry after the patient had slept in them two nights, without being disinfected, on Dec. 15.

The infected sheets sent to the wash on Dec. 15 were returned on Thursday, Dec. 22.

Some of the above sheets, returned on Dec. 22, were placed on the beds on Monday, Dec. 26.

Clean (?) sheets placed on beds on Monday, Jan. 2.

The same patient presenting smallpox eruption on Nov. 24 or 25. Probably exposed to infection on Nov. 10.

Smallpox eruption appeared in cases 2 and 3 on Dec. 14 and 15 respectively.

Probably exposed to infection on Dec. 1 and 2.

Eruption of smallpox appeared in Case 26 on Dec. 29. Probably exposed to infection on Dec. 15.

Three cases showed the eruption on Thursday, Jan. 5. They were therefore probably infected on Friday, Dec. 23.

Three presented the eruption on Jan. 7, and were therefore infected on Dec. 25.

Seven cases presented the eruption on Monday, Jan. 9. They therefore received the infection on Dec. 27.

Smallpox eruption appeared in Case 20 on Jan. 15. Infection received on Monday, Jan. 2.

It follows, that if it be true that the disease was propagated through the medium of the laundry, the present

outbreak teaches us some very important practical lessons, some of which are :

1st. That the disease is communicable during the period extending from the commencement of the fever to the appearance of the eruption ; and that any cases showing febrile symptoms during such an epidemic as we have lately experienced should be closely watched, in order that they might be isolated early and the linen be thoroughly disinfected.

2nd. That the ordinary temperature of the water in which infected sheets are washed—which are *said* in this instance to have been boiled—is not sufficient to destroy the fever-poison.

3rd. The importance of disinfection of all linen used by patients suffering from this disease by any of the ordinary disinfectants generally employed. After the 22nd or 29th of December all the cases attacked were discovered before the linen-changing days ; the sheets were therefore thoroughly steeped in a solution of carbolic acid before they were sent to the laundry. It is a fact worth observing, that but two cases were infected that could be attributed to the sheets after the above dates.

This outbreak also supplied us with farther evidence, if any were required, of the protective power of re-vaccination against smallpox. On the 12th of January almost all the patients and inmates were subjected to this operation, and there has not occurred a single case of smallpox since the 14th of January.

Besides the care taken to disinfect the sheets in all the cases after the 22nd of December, much of our immunity from the disease after this date is no doubt to be attributed to re-vaccination.

In connection with this subject, we have to consider the subject of recent vaccination at the same hospital. At the present time this is so important a question, and the profession is so deeply interested with it, that we shall perhaps be thanked for allowing the obstetric assistant, Dr. Richard Wilson, who had charge of the matter, to speak for himself. He says :

In the month of November of the past year (1870) the first case of smallpox broke out amongst the patients at St. George's Hospital (this patient had been an inmate for eleven weeks previous). In a short time several more patients were attacked, increasing the number to eighteen. It will not be necessary for me to give an account of the cases of smallpox, as a full report regarding them will be found in Dr. Jones's paper (see page 229). I propose merely to give the results of the vaccination. As the disease was still spreading, it was resolved by the board of the hospital, at the recommendation of the medical staff, that all the nurses and patients in the hospital should be at once vaccinated, that only urgent cases should be admitted, and that these should be vaccinated, if thought advisable. It was also resolved that the visits of the friends of the patients should be stopped. These measures were speedily taken, and from that time there was no farther increase of smallpox in this hospital : whilst at this date (March 28th, 1871) it is gratifying to observe there is not a smallpox patient remaining in the hospital, proving how necessary it is to apply the usual precautions ; and when these are carried out effectually, how certain is the result. The vaccination was commenced on the 13th day of January.

Three methods of vaccination were adopted, namely, puncture, abrasion or scratching, and vesication. The puncturing was performed in the ordinary way ; that is, by grasping the arm (usually the left) with the left hand, drawing the skin tense, and then making from four to five punctures down to the cutis-vera with an arrow-headed lancet, having a central groove running to the point ; and in this groove the lymph was placed so that it flowed well into the puncture. If points were used, these were slightly moistened, passed into the puncture, and allowed to remain there about three minutes, to give the lymph an opportunity of being absorbed. In abrasion or scratching the arm was held in the same manner as for puncturing, but an ordinary bleeding-lancet used, and two or three small

parallel scratches were made, taking care that they were only deep enough to allow the smallest quantity of blood to exude ; the lymph, if liquid, was then rubbed well in with the point of the lancet ; if points were used, these were first moistened by the breath, and rubbed into the different scratches, until they presented a shining appearance. Vesication : three or four small blisters were made by means of a blistering-fluid the night previous to the vaccination ; on the following day they were pricked to allow the serum to exude, and then the lymph was applied to the raw surface.

From the number of cases vaccinated in the hospital, it has appeared to me that the scratching was much more effectual than the puncturing. I am not in a position to speak as to the success of vaccination by blistering, as only a few cases were treated in that way. I think that it is necessary to take one or two precautions in vaccinating by means of scratching—namely, that persons advanced in years, or those presenting an unhealthy appearance, should not be operated on in this manner, as we have had as a result several cases of very inflamed arms. The arm becomes swollen and red, the inflammation and swelling often extending to the hand ; the glands in the axilla become affected ; and very often the vesicles slough, leaving sores which have to heal up by granulations. It seems also necessary that the scratches should be *parallel*, and not crossed, because under the latter circumstances the skin is much more likely to die.

(To be continued.)

## METROPOLITAN FREE HOSPITAL.

### Ulcer of Stomach.

(Under the care of DR. C. R. DRYSDALE.)

Reported by MR. WILLIAM KIPLING.

*Family History.*—Father living, thirty-six years of age ; mother died at forty-two, of a tumour in the stomach ; three brothers living in good health.

*Previous History.*—Patient is nineteen years of age ; unmarried ; used to work a machine. Had rheumatic fever a year ago, and was laid up for eight months.

*Present attack.*—Came on three years ago with tenderness over her epigastrium and pain at the back between her shoulders, which was increased directly after she took any food and was followed by vomiting, the vomited matter was sour. She also had hæmatemesis, and vomited as much as half a pint of blood at a time, and sometimes twice a day. She has since that time been under treatment at the German Hospital (fourteen weeks) ; Bartholomew's Hospital (six months) ; Brighton Hospital (four months) ; and London Hospital ; and during the intervals at home under medical advice, but has not experienced much relief.

Admitted here August 11th with the following symptoms :—Pain at the epigastrium and between the shoulders, the former increased by pressure, and over a surface the size of the palm of the hand ; vomits about three times a day, and with clots of blood in the vomited matter occasionally ; her lips are very much blanched ; feels faint and languid ; swimming in the eyes and muscæ volitantes ; catamenia absent for two months ; before that, they were regular and attended with pain ; has leucorrhœa ; has flushings of the face through the day.

Pulse 100 ; tongue furred ; bowels constipated, and motions black ; abdomen tympanitic ; heart and lungs normal ; seems to be well nourished.

During the time she has been here, she has had the above symptoms all along, and been under the following treatment :—

R Tinct. opii, m. x ;  
Mucilage, ʒss. t.d.s.

For a week but no benefit.

R Argent. oxydi, gr. j.;  
Pulv. opii, gr.  $\frac{1}{2}$ ;  
Acacia q. s.  
Missi. fiat. pilulæ. ter. die.

Four days no relief.

R Argenti. nit., gr.  $\frac{1}{4}$ ;  
Miccæ. panis. q. s.  
One omni. mane. et. nocte.

For two weeks but of no avail. She has a hypodermic injection of morphia, gr.  $\frac{1}{3}$  every night to relieve pain. Has had her epigastrium blistered occasionally, which relieved the pain a little.

R Acid sulphurosi,  $\overline{5}$ ss.;  
Aqua,  $\overline{3}$ ss. t. d. s.

Four days no good result.

R Tannic acid, gr. j.;  
Zinci. sulph., gr.  $\frac{1}{2}$ ;  
Aqua,  $\overline{3}$ j. t. d. s.

Five days but of no use.

Since then, September 22nd, till the present time, October 16th, she has been taking gradually increasing doses of bismuth trisnit. : commencing at 10 grain doses with mucilage  $\overline{3}$ j. three times a day up to  $\overline{3}$ j. doses in mucilage, the same number of times a day, and says she has received more benefit from it than from anything else she has had. She has had ice to suck when there has been much clotted blood in the vomited matter, but she has only had three attacks of hæmatemesis since she has been in the Metropolitan Free Hospital, to the extent of about five ounces, and that within the last two weeks. October 16th, she has been fed by the mouth with beef tea, milk (sometimes mixed with lime water), brandy, which she alleges "does her good," but which Dr. Drysdale is much opposed to her taking, jelly, light pudding, &c., but she cannot bear solids. She has had no nutritive enemata by the rectum, as she had them at the hospitals mentioned at the beginning of the case, sometimes for six weeks at a time, and was forced to leave on account of their disagreeableness. Her bowels have been kept open by means of warm water injections, but lately they have been opened by means of the primary current of Stöhrer's battery, one pole being placed upon the sigmoid flexure, and the other moved from the ascending colon of the right side along the transverse one, and then down the descending colon, and this has proved to be very effective.

The points of interest in this case up to the present time are, that she has not required the use of injections since Faradisation has been applied by Mr. Kipling: it has been remarked, that  $\overline{3}$ j. doses of trisnitrate of bismuth have been well borne, and lastly, that when the patient made use of (for three days) an entirely milk diet, her symptoms were greatly relieved, and there was less blood vomited than at any other period. This treatment would then have been persevered in, would the patient have submitted to it; but she had such a craving for brandy, that had she not been supplied with a moderate quantity of it, she would have probably left the hospital, as she seemed to have done others in former experiments which did not please her.

## CLINICAL RECORDS FROM PRIVATE AND HOSPITAL PRACTICE.

### I.—OXYGEN IN DISEASES OF THE LUNGS.

By HENRY N. READ, M.D., House-Surgeon, Long Island College Hospital.

THE cases taken from observations extended over about a year's time, during which period oxygen gas has been used in the Long Island College Hospital, and include cases of phthisis pulmonalis, pneumonia—acute and chronic—and chronic bronchitis. Only those cases have been reported in which the gas was used regularly, and for a suffi-

cient time to warrant the drawing of a conclusion as to its effects; and a large number of cases in which the patients left a short time after commencing its use, or in which the observations were not sufficiently accurate, have been thrown out:

CASE I.—Bernard Fratus, aged thirty-four; Portugal; sailor; admitted July 19, 1870. Was admitted to surgical wards for anal fistula, but in a short time was transferred to the medical side for trouble with his lungs. History: Nine months ago he caught cold, which was followed by cough, bloody expectoration, pain in the side, etc.; was in bed only a few days, and then resumed duty on shipboard; from that time, however, he has had a constant cough, with expectoration of thick mucus, but has had no hæmoptysis; has lost flesh and appetite. Physical examination gives dulness at base of right lung, mucous râles, increased vocal resonance, bronchial breathing, etc. Has hectic and night sweats; temperature ranging from 100° to 101°; pulse, 100 to 105. Gives no family history of consumption. Ord. ol. morrh., with three gals. gas daily; generous diet. Weight 128 pounds.

August 10th.—No improvement manifest except in regard to appetite; temperature as at last record; night-sweats continue; treatment continued.

August 26th.—Marked improvement. Night-sweats disappeared; temperature averages from 98° to 99°; has gained four pounds in weight. Ord. one additional gal. of gas, making four gals. in all daily.

September 29th.—During the last month there has been a steady improvement. The expectoration, which was at first copious, has almost entirely disappeared; the râles are no longer heard in the lung, and the respiration is almost normal. Weight 136 pounds. Appetite continues excellent.

October 19th.—Patient discharged to-day, and goes to sea again. Weight 139 pounds—a gain of 11 pounds. Feels as strong as ever and has no cough.

CASE II.—James Mulligan, aged twenty-six; Ireland; sailor; admitted September 8, 1870. Patient gives history of hereditary tuberculosis; has lost several relatives from consumption. He has had cough for ten months, with the characteristic yellow sputa; has had hæmoptysis several times; is much emaciated, weak, and sallow; the general tuberculous "habit" strongly marked. On examination a cavity is detected at the apex of the left lung; amphoric breathing, with the cracked-pot sound, very marked. Anorexia, hectic, etc. Was ord. ol. morrh.; four gals. gas, daily, also the free use of whiskey, with milk and nutritious food. Weight 133 pounds.

October 16th.—Patient's condition slightly better, but no marked improvement; has better appetite and less hectic; still coughs badly; average temperature, 99 $\frac{1}{2}$ °; pulse, 100. No perceptible change in the physical signs.

December 2nd.—Apparently much better; has gained six pounds in weight; night-sweats have disappeared; has a good appetite; temperature 99°; pulse 90 to 92 average; cough still troublesome. Ord. the following *mistura tussis*:

R. Chloral hydrat.  $\overline{3}$  ss.  
Liqu. opii comp.  $\overline{3}$  ij.  
Syr. Tolut.  $\overline{3}$  iss.  
Aq. q. s. ad  $\overline{3}$  iv.  
M. Sig. teaspoonful, pro re nata.

February 1st.—Not so well as at last record; has lost four pounds in weight. Pulse and temperature the same; cough better. Suffers from nausea; bowels constipated. Ord. porridge for breakfast, and a laxative pill after dinner. Same treatment continued.

March 5th.—Has improved steadily the last month. Is stronger than at any time since his admission, and takes a great deal of exercise. Has gained five pounds in weight. Physical signs show improved condition of the lung, and the cavity is quite empty. Treatment continued.

## Transactions of Societies.

MEDICAL SOCIETY OF LONDON.  
OCTOBER 30TH, 1871.

DR. ANDREW CLARK in the Chair.

## FIBROID PHTHISIS DEPENDING ON TRAUMATISM.

MR. VICTOR DE MERIC narrated the following case:—

April 1st.—Continues to improve.  
May 14th.—Patient discharged to-day, and returned to work; but is advised not to go to sea again. Weight 147 pounds. Strength and general condition very good. Cavity still empty, and no abnormal sounds heard beyond the cavernous breathing, and puerile respiration in healthy portions of the lung.

CASE III.—Thomas Hughes, aged twenty-nine; Ireland; sailor; admitted September 8, 1870. On admission right lung was found dull on percussion at apex, dulness extending as far down as fourth rib; bronchial breathing, voice-sounds increased; mucous *râles*, etc. Has considerable aphonia, anorexia, and hectic. Has had cough and expectoration for three months, but hæmorrhage has never occurred. Inherits the tubercular diathesis. Weight 134 pounds. Pulse ninety-five. Temperature  $98\frac{1}{2}^{\circ}$  to  $99^{\circ}$ . Ord. ol. morrh.; four gals. gas daily; good diet, etc.

October 12th.—Some improvements; cough much less troublesome, and expectoration less. Has a good appetite, and has gained one pound. Pulse 98 to 100. Temperature  $99^{\circ}$  to  $99\frac{1}{2}^{\circ}$ .

December 20th.—Has one or two slight hæmoptyses, and has sharp pains through right side, otherwise a little better.

March 5th, 1871.—During the winter months, the patient got alternately better and worse; no very decisive alteration taking place either way. In the month of January the gas was increased to six gals, and the oil to  $\bar{3}$  iij. per diem; but producing no corresponding change, were reduced to the original quantity. At present the physical signs are not so marked as formerly, and the cough is almost well, but he has lost four pounds in weight.

April 1st.—A decided improvement manifest since last record; has gained three pounds; pulse and temperature normal.

May 17th.—Strength and condition of patient very favourable, *râles* disappearing from lung; and the respiration, though exaggerated, is not bronchial; signs of consolidation have almost disappeared. Weight 136 pounds. Does work about the hospital, and is in a condition to be discharged.

CASE IV.—William Dan, aged forty-eight, Denmark, printer, admitted November 5, 1870. Been affected with cough and copious expectoration of yellow mucus for the last four months; is extremely emaciated and weak, and has exhaustive night sweats; has had several hæmoptyses. A large cavity detected in apex of left lung, also slight tuberculous deposit in upper portion of right lung. His father died from consumption. Weight 116 pounds. Temperature  $101^{\circ}$ . Pulse 105. Ord. ol. morrh. with four gals. gas daily, and good diet.

December 17th.—Decided improvement. All bad symptoms have abated. Weight 125 pounds.

March 1.—1871.—For the last two months the patient has been declining; an exhaustive colliquative diarrhœa supervened, which resisted all attempts to check it. The quantity of gas was doubled, but owing to the development of unpleasant effects, was discontinued. He has lost all the flesh he gained, and five pounds besides. Weight 112 pounds.

April 3rd.—Worse. Both lungs hopelessly involved, and the constant expectoration, night-sweats, and diarrhœa, are wearing the patient out. Has lost two pounds more.

May 15th.—Patient evidently sinking, is treated at present only in reference to his symptoms.

The result in this case was unfavourable; a decided apparent improvement for the first month or six weeks, was followed by a steady decline, tubercles rapidly developing throughout the whole of the right lung, which was, at admission, only slightly affected. A thorough trial of the gas was made, assisted by all the usual remedies, but it proved in this case inadequate to check the disease, and, at the present writing, the patient can apparently live but a short time.—The case was analogous to Cases II. and III., the diathesis being hereditary in all, but the disease was much farther advanced at the date of admission.

(To be continued.)

The patient, æt. forty-five, was forcibly raised from the ground by his assailant, who attempted to throw him into a wine vat, some of the lower ribs on the right side suffered fracture near their angles. He was sent to the London Hospital to have a broad bandage applied. On the fourth day the bandage was comfortable, and there was no dyspnoea or fever. During the next few days, the symptoms became alarming; hurried breathing; severe pain in the left side of the chest; restlessness; anxious countenance, and abundant expectoration. On the 11th, the patient was in a typhoid state, the whole of the left side of the chest being dull on percussion, and offering no respiratory sounds whatever. The right side sounded well, the respiration being quite puerile, it was concluded that from pressure or shock, the left pleura had been injured, that effusion had taken place, and that the case was one of acute pleuro-pneumonia. The negative symptoms were absence of pain or stitch, and no bulging of the intercostal spaces. The patient gradually rallied, and at the end of two months left his bed; the physical signs varied but little; the cough and dyspnoea were at no time very distressing. It was thought that, since succussion produced no splashing, false membranes were lining the pleura costalis. About ten weeks after the assault, faint gurgling began to be heard towards the apex of the left lung, and it was supposed that the left lung was getting partially freed. The gurgling soon, however, assumed the character of air passing through a small vomica filled with fluid. It was regarded now as a case of phthisis of long standing, followed by the complications described. The fractured ribs had united, the patient gradually sank and died on the ninetieth day after the accident. P. M.—Right lung collapsed, filled two-thirds of the cavity, adhesions and several tuberculous circumscribed deposits in it, varying in size from a pea to a walnut; on the left side lay a large dense greyish-looking mass, occupying four-fifths of the whole cavity. It was extremely hard, and had contracted adhesions—the pleural fluid on both sides (four ounces) was reddish and small in quantity—the left lung formed a solid mass, composed of tuberculous fibroid infiltration; on section, no trace of vessels, air tubes, or air cells could be made out, no oozing was perceived; not a sign of breaking up or of pus, and, of course, no vomica; heart atrophied; the man supposed himself to be healthy; his occupation was laborious; there was no family history of phthisis, we must, therefore, suspect that the pleuro-pneumonia did the mischief, though it is difficult to believe that the induration would be so extensive, if some previous pathological changes had not been present; the importance of the bulging of the ribs and dyspnoea is shown in this case. The presence of tubercle in the right lung, suggests that it might be present in the left also. Ninety days were hardly sufficient to transform the left lung from a perfectly healthy state to the mass above alluded to.

DR. DOUGLAS POWELL was unable to understand why this was called a case of phthisis, he would consider it from an examination of the specimen, and the clinical history, a case of pneumonia in the grey stage.

The PRESIDENT remarked that it was not a case of what he called fibroid phthisis, which would present ulceration and supuration of a more or less circumscribed non-malignant deposit in the lung. If there was no cavity, there was no phthisis. Some bronchi become blocked by exudative fluid matter collecting in them, and gives rise to gurgling. The specimen was an excellent example of the hard form of grey pneumonic consolidation.

## POLYPUS OF THE EAR.

MR. JOHN PENNEFATHER showed a large gelatinous poly-pus, extracted from the ear by means of a spring forceps, which he prefers as a more simple and effectual method of removing these growths. He then read a paper on

## THE SENSE OF HEARING.

By experiments with the air pump, it was proved that a vacuum surrounding a body rendered it incapable of emitting

sonorous vibrations, that sound is produced primarily by the vibration of a sonorous body, but that the composition of that body and the atmosphere surrounding it, materially affected the radius to which the pulses of sound were transmitted. That the pulses of sound were conveyed in undulating waves which is fully illustrated by casting a substance into the water, the circular undulations gradually expand until the inceptive force is expended. But, on coming in contact with an unyielding structure, the ripples leap up and surround it again uniting, but with decreased force, should there be a hollow space in the fixed object, it will be observed that the water rushes in with increased violence; so in the sonorous undulations of sound, as the pulses strike the sides of the cranium, they surround and rush into the entrance of the external ear, with augmented power. Allusion was then made to the way in which the sonorous vibrations may be directed to a given point by reflectors. Mr. Pennefather then traced the comparative anatomy of the organ of hearing from its first rudimentary structure through the different orders of creation, to its perfect development in the mammalian class, showing what was essential in the organic structure for the mere perception of sound, and for the perfect realisation of the sense. The manner in which the sonorous waves were transmitted to the internal ear was then explained. The author contended that writers on this subject were in error in supposing that the bones of the head, or the air contained in the tympanum, had any power of conduction, unless the sonorous body was in actual contact with the cranium. The structure of the internal ear, with the cords of Corti, was then explained and demonstrated, both by microscopical preparations and plates.

A spirited discussion ensued, in which Dr. Routh, Dr. Symes Thompson, and Dr. Dalby took part.

MR. TEEVAN then exhibited

(1.) A new Lithotrite, having a square heavy handle, and a vertical slide, instead of a button. The heaviness of the handle permitted the lithotrite to glide in more easily than others; its squareness combined firmness of grasp with the greatest delicacy of manipulation, and the pressure of the thumb on the slide was a more simple action than thrusting a button to and fro.

(2.) A syringe for deep urethral injections, very small, of glass, and having an elastic nozzle five inches long, surmounted by a ball, attached to it. An elastic nozzle was infinitely preferable to a metal one, and the ball permitted accuracy of application, for on account of the alterations in the length of the penile, urethra measurement could not always be depended on.

(3.) A syringe for patients to use in gonorrhœa or gleet, made of a small elastic ball, with a bony nozzle three and a half inches long; it was durable and inexpensive.

Mr. Teevan also exhibited the bougie olivaire à ventre, the bougie à trois boules, and M. Mercier's Sondes coudées et bicoudées.

## Foreign Medical Literature.

### DR. ULLERSBERGER ON ELECTRICITY

IN

#### DISEASES OF CHILDREN.

A PRIZE having been offered by the Editor of the *American Journal of Obstetrics* for an essay on the use of electricity in the treatment of the diseases of children, it was won by Dr. Ullersberger, of Paris, and his elaborate essay, translated by Dr. McLean Hamilton, is appearing in the pages of our valuable contemporary.

The following is an abstract of the prize essay in question:—

The notable advantages of the remedy are:

1st. The patient has little or no fear or aversion to this mode of treatment.

2nd. It admits of the possibility of modifying the degree of application.

3rd. It is impossible to produce the special lesions of the skin.

4th. There are means of applying this remedy on all parts of the body, even to the most inaccessible.

5th. The operation of electrification occupies very little time, is of short duration, and requires but few preparations.

6th. The operation, after being performed, does not leave pain, like the cautery, and all the revulsions of more or less intense effect.

The enumeration of the advantages of electric medication leads us to the question: "What is, then, the general effect of medical electrification?" Its effect is to *invigorate and stimulate those nerves* whose function has been weakened: to calm the irritable or irritated nerves; to compel paralysed nerves to contract; and to restore tetanised nerves. It stimulates or suppresses the glandular secretions; it can change solid matters so as to favour their absorption; and will bring together material for the formation of solid matter—*i.e.*, in checking muscular atrophy, a continuous application of electricity excites contraction of the fibres of cellular and connective tissue; it increases the activity of the lymphatics, causes contraction of the capillaries, and increases the tone of the vessels.

Electricity, when used in medicine, is applied in four different ways:

1. *By Frictional Electricity* (rubbing).

2. *By Contact* (galvanism). Of the electricity of contact the following currents are used in preference, and to accomplish the following results. (a.) An electro-dynamic current, in order to change the action of the nervous system; (b.) an electro-chemical, for producing decomposition, reduction, oxidation, precipitation, and coagulation; (c.) an electro-thermal, for calorification, cauterising, and destroying by heat.

3. *By Magnetism* (electro-magnetism); and finally,

4. *By Electricity*.

The two last modes of inducted electricity (Faradisation) can only be employed when the currents intermit to produce shocks, irritation of the nervous system, and of the contractile tissues.

The action of the constant current (*dynamic electricity*) on the motor nerves was made known by Remak;\* previously Nobili, Matteucci, and Eckhardt, had observed that a continuous galvanic current which was used for stimulating rendered a part of a nerve insensible. By this discovery Remak profited, and he used the current to cause contractions for overcoming shortening. A current of 30 elements of Daniel, conducted for several moments through certain contracted muscles, produced a mollification, and re-established the will over the flexors. When used in shortening, deviation, contraction of the muscles, and paralysis, great improvement was manifested in a few minutes; in other cases it was of no avail.

The mollification and relaxation of such contractions are now constantly effected. The electric current acts as a stimulant on all the sensory nerves, and is consequently applicable in all cases in which stimuli are generally indicated.

The degree and duration of stimulation should be proportioned to the individual susceptibility. In an irritable individual it is necessary to commence with a current of the least intensity and duration. It follows that congestions, inflammations, and feverish affections form contraindications.

But what then is the effect of the constant current? It increases the conductivity of the muscle; it is an excitor of the nerves and muscles; it penetrates and agitates, and as a diffusive stimulant congests the tissues it traverses.

The general effects are the following:

1. Increased supply of blood with simultaneous elevation of the temperature of the parts under electric stimulation.

\* Robert Remak: *Galvanotherapie der Nerven- und Muskelkrankheiten*. Berlin, 1858. 8vo.

† Comp. Dr. H. G. Hammer, director der electrischen Heilanstalt zu Dresden: *Die Electricität als fortanfende bildende und erhaltende Kraft*. Dresden, 1855. 8vo.

2. Increased energy of the contractile power of the walls of the vessels.

3. The electric current prevents and overcomes these changes, secondary and consecutive, which are manifested by inactivity of the nervous and muscular radii.

4. It re-establishes the lost or suspended power of the nerves, and it consequently stimulates innervation.

5. It is capable of provoking a supplementary activity in the non-paralysed nerves. We can use the electric current as an excitor of muscular power in paralytic affections.

It is precisely in such cases that it has been heretofore employed, as also in cases of anaesthesia or lost sensibility.

Electric stimulation is capable of restoring, under certain conditions, the vital energy of the motor-nerves and muscles, when weakened or entirely suspended.

It can regulate or effect material transformation in the parts mentioned.

Electricity exerts a special effort on the systems of locomotion and nutrition; it exerts a reflex compensation.

Stimulated innervation can produce absolutely the same physiological phenomenon as electrification—that is to say, elevation of temperature; acceleration of pulse; division of fluids; increase of the secretions and excretions; congestion of the skin and contraction of the muscles.

#### METHODS OF THERAPEUTICAL ELECTRIFICATION.

Medical electricity comprises static electricity, electricity by contact, electric bath, electric spark, discharge by the Leyden jar, electric blowing, electricity by the brush or the pincers. Electrification by these modes is very rarely employed. The dynamic, which is divided into—

1. Electricity by contact (galvanism), subdivided into (a) continuous current, (b) an intermitting current.
2. Inducted electricity (Faradisation), thus called by DuChenne of Boulogne, after the name of the inventor.

They take their source either from a galvanic column (apparatus of Volta, electric or electric-dynamic,) or by magnetism (rotatory magneto-electric apparatus).

#### METHODS OF LOCALISED ELECTRIFICATION, LOCALISED FARADISATION.

1. Electric irritation of the skin. We Faradise the skin, (a) by means of the electric hand, (b) by means of the metallic exciters, (c) by means of the electric wires, electric flagellation, or on a single point the electric moxa.

2. Electric irritation of the muscles, muscular Faradisation, which is direct, or indirect Faradisation of a nerve or muscle in the normal state, produces always a contraction, or sensation. The indirect presupposes an exact knowledge of the position and the direction of the nerves. The muscular consists in that each individual muscle is contracted; we become aware of this when we place the damp electrode over the parts of the skin which correspond to the surface of the muscle. Electricity, under the influence of very strong currents, can penetrate deeply in the tissues.

3. Faradisation of the internal organs—the organs of sense; the genital parts of man; the rectum; the anus; the pharynx; the oesophagus; the bladder; the larynx. The Faradisation of these parts requires special instruments.

Faradisation of the stomach, lungs, or heart, is only affected by the indirect Faradisation of the pneumogastric. Faradisation, applied to the treatment of disease, should be applied every day, or every other day. It is not well to prolong the *séances* more than 10 or 15 minutes. We apply it in centrifugal or centripetal currents, or by irritating the peripheral ends of the nerves by the electric currents.

Localised electrification consists then in this: that the effect of the electric current is confined to the skin, a branch of a nerve, or a nerve-fibre, a single muscular fasciculus, or finally to the internal organs, by irritating directly or indirectly their nerves. These operations do not injure the skin, and we use in their performance wet or dry metallic exciters (sponges in metallic cylinder).

In one instance the dry metallic exciters only produce on the skin an irritation limited to it; in the other, the wet exciters, applied to the wet skin, cause the electric currents to penetrate the skin without irritating it, and diffuses them through the organs immediately beneath.

We have, as established galvano-therapeutical rules, the following:

1. The descending extra polar electronus should be in preference employed, when it is desirable to restore a pathological excitability, an anomaly of irritability, around the peripheries of the nerves, to their normal state.

2. The extra polar catelectronus, on the contrary, should be used where lowered excitability or diminished excitation exists at the periphery of the nerves, that is to say, the muscles that are to be restored.

3. The indication for the production of the anelectronus and of a localised ascending catelectronus, should start absolutely from the same point of view. The electronus is in general contraindicated in increased excitability, while the other, the catelectronus, is contraindicated in diminution of excitability in the central part of the nerves—in the central spinal ramifications and the roots of origin of the nervous fibres.

We have characterised the therapeutical value of the currents of tension “die spannungströme” in the following manner:

1. They are able to render the same service as the Faradaic currents.

2. Against complete paralysis of sensation of the integument; the currents of tension, separated a certain distance from the skin, operate with much more force than the Faradaic and constant currents applied by means of the electric flagellation.

3. It is, without dispute, the energetic effect of the immediate currents of tension directed over the flat muscles and vessels of the skin, which dissipate the passive hyperaemias and puffy swellings of the skin which are secondary in the aforesaid paralysis.

In 1867 Dr. Joseph Dropsy, of Cracow, presented to the International Medical Congress a memoir on generalised electricity, founded on new processes, from which we take the essential points.

It is necessary, in treating diseases of the centrifugal function, to apply positive electricity to the top of the head and to the pit of the stomach, and negative electricity to the hands and feet. It is necessary, in treating diseases of the centripetal function, to use negative electricity at the top of the head and to the pit of the stomach, and positive electricity to the hands and feet.

1. The sensitive nerves can only respond to effects to which they are forced through their physiological nature.

2. The motor nerves will contract or retract.

3. The trophic nerves will only serve the purpose of nutrition, and the transformation of organic and organised substances. They will lend themselves to the processes of secretion and excretion.

We have stated in our general rules of electro-therapeutics, that the causes of the affections submitted to electricity must never be lost sight of, and as diseases of motility are the most frequent, we will examine the etiology of the disorders of motility without paralysis. It can be produced, (a) by alteration of the sensibility, (b) by derangement of the equilibrium of the antagonistic muscular parts, (c) by suspension of the localised power of movement, (d) by a disproportion between normal impulse of will and excitability, as well as the conducting capacity of the different parts of the nervous system, (e) by general disturbance of the cerebral functions without total suspension of the last.

1. The antispastic effects of the constant galvanic current manifest themselves visibly, (a) against the reflex spasms (*i. e.*, cephalosprimes), (b) against trembling of the limbs, (c) against paralysis agitans, (d) against myastagmus (comatrigii), (e) against stuttering, (f) against chorea.

2. The antiparalytic effects are seen, (a) against partial secondary paralysis, and atrophy, with or without contrac-

tions, as the sequela of articular or muscular rheumatism, (b) against primary and secondary atrophies of the muscles "das premierstades," (c) against traumatic paralysis, (d) against hemiplegia, (e) against paraplegia, and tabes dorsalis.

3. The catalytic effects of the constant galvanic current are seen: (1) by dilatation of the vessels which contain blood, and of the lymphatics which clear the cells of blood, or of stagnant lymph, then by reabsorption of effusions, establishing a circulation of fluids in the interior of the tissues. (2) By a chemico-electrolytic change, joined to an electrodynamic removal of the fluids. (3) By diminution of pain after lesions and traumatic inflammations.

We may thus rely on these catalytic effects.

1. Against phlegmon of the joints—either acute, traumatic, or chronic; (a) against chronic articular or muscular rheumatism of the tendons, of the sheathes or periostitis; (b) against neuralgia; (c) against deep-seated inflammations of the spinal cord—the consequences of which are paralysis of the lower extremities, of the urinary organs, and of the rectum; (d) against deep-seated inflammations of the brain, accompanied by trembling and other spasmodic paroxysms. (2) Against exudations (hydrarthrosis). (3) Against painful and inflamed tumors.

The continuous currents, operating rapidly or slowly, then the interruptions, rapid or slow, of the successive currents, produce different effects, consequently a complete apparatus should be constructed in order that the current may operate by shocks which succeed each other rapidly or slowly; the effects of the rapid discharges of the current on the muscular contractility of the muscles is condensed in the inducted current, and is relaxed very soon after the suspension.

In this last case, the less rapidly the discharges follow each other, and the shocks produced by the suspensions diminish, the more rapidly the separate discharges follow. The muscular sensibility is more powerfully stimulated by rapid discharges of the current than by interruptions which slowly follow each other. The muscular tone is increased by the rapid discharge of the current as soon as it is diminished, and returns to its normal state; a prolonged influence of the current can even produce contraction of the muscle.

The nourishment of the muscles is more active under the influence of currents rapidly discharged, which may be observed in atrophies.

The electro-cutaneous sensibility is much more stimulated by a strong current rapidly discharged than by a slowly interrupted current.

#### A New Syringe for Uterine Injection.

At a meeting of the New York Obstetrical Society, Dr. B. F. Dawson exhibited a new instrument for uterine injection. It consisted of a silver tube, which is enclosed by two steel blades or valves, which can be opened by pressure upon the handles of the instrument, thus dilating the uterine canal, allowing all fluid to escape which may be thrown in by the syringe attached to the extremity of the injector tube. The opening and closing of the valves present the additional advantage of breaking up and removing any clots which may be in the uterine cavity, and collect so as to prevent reflux.

Dr. Noeggerth said he had used the instrument, and found it a good one. Where uterine catarrh has existed a long time, and the tissues are soft and readily dilatible, the instrument will be of service; but where the disease is recent the tissues are too firm to allow of much stretching by such an instrument. The facility with which clots can be broken up and removed is a good feature in the instrument. It is not the entrance of the fluid nor the exit which sometimes occasions death; certain substances occasion death by reflex action resulting in an inflammation; the liquid goes to the depth of the utricular glands, which extend deep into the uterine tissue. The sesquichloride of iron, nitrate of silver, and chloride of zinc have occasioned death.

Dr. J. C. Nott said he had also used Dr. Dawson's instrument, and thought it possessed many points of merit; he

asked if there is danger in the injection of iron for hæmorrhage when the uterus is dilated.

Dr. Noeggerth believed the subsulphate of iron less dangerous than the sesquichloride, from the use of which he once occasioned a metro-peritonitis.

Dr. J. G. Perry said he had seen flabby uteri contract vigorously on the injection of iodine. Dr. T. A. Emmet said he had seen such vigorous contraction as to eject the iodine which had been introduced.

Dr. E. R. Peaslee said that in metrorrhœa, metrorrhagia, or hæmorrhage proper, the utricular glands are full, so that by injection he thought no fluid would pass into the glands; it is not necessary to have the injected fluid pass into the glands to get up sudden contraction, for the surface itself is very sensitive.—*American Journal of Obstetrics.*

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 15, 1871.

### MEDICAL ASPECT OF THE FRANCO-GERMAN WAR.—No. III.

*Pyæmia.*—No hospital, whether of the Army or under the Red Cross, seems to have been exempt from pyæmia. Of 117 deaths from all causes in the hospital of the American Ambulance at Sedan, thirty at least were from pyæmia. In other places this affection is alluded to as "that hideous scourge;" and it is stated that it was, under certain conditions, as common in small as in large buildings. On 12th August the disease attacked a case of gunshot fracture of the left arm; others soon followed, and ended in death from the twentieth to the twenty-seventh day after the receipt of the wound. The disease occurred only in cases of gunshot fracture or amputation, and in wards, the conditions of which were most insanitary. Here, for example, is a specimen:—"Cases accumulated to overcrowding for a period of three weeks in a building by no means truly adapted to hospital purposes, the surrounding air being, moreover, strongly tainted with cadaveric miasm."—P. 113. Nor was it found practicable, after the disease had once appeared, to check it by what are usually called "sanitary" means, for "the most thorough disinfection was carried out, the utmost cleanliness maintained, and all available means for securing efficient ventilation were carried into effect; the patients affected with

pyæmia were removed to a large, well-ventilated shed in the garden"—"all in vain." In this war, as in all others, it has been shown that, wherever large accumulations of wounded took place, there pyæmia, in one form or other, appeared, and proved as fatal as it had ever done.

*Disinfectants* would appear to have been more extensively used during the late war than on any previous occasion. Perhaps there were circumstances which justified the profuseness of this expenditure, although the question naturally presents itself, Would they not have been in some measure at least unnecessary had simple cleanliness and free ventilation been fully enforced? Many allusions to the employment of artificial substitutes for these purifiers occur in the Report. At p. 22 we read that, "the advantage of the free use of disinfectants, especially carbolic acid, for purifying the wards, and for washing, when diluted, the wounds, has been shown, and will never be forgotten." But disinfectants were not of themselves sufficient to prevent injury where cleanliness was imperfectly carried out. A large number of cases of bad wounds and diarrhœa having been removed from tents and distributed through the wards of the Anglo-American Ambulance at Sedan, the old patients there contracted diarrhœa and purulent infection, notwithstanding that disinfectants and free ventilation were employed. Pyæmia also prevailed to a great and fatal extent, although "carbolic acid, besides disinfectants, &c., were largely used in washing the floors and deodorising the privies and heaps of refuse abounding in the neighbourhood."—P. 112. The real state of the case seems, indeed, to be, that where sick or wounded are crowded together, or cleanliness neglected, disinfectants were really useless, in so far as prevention of hospital disease is concerned, and the question not unnaturally presents itself,—Is it not now far too much the fashion to trust to them?

## Notes on Current Topics.

### Alum Adulteration of Bread.

The existence, amount, and facility of detection of this adulteration has been thoroughly discussed in Melbourne recently. The *Pharmaceutical Journal* says that samples of the bread of the whole of the bakers in Melbourne were seized by the police, and in every instance the Government analyst found alum. The bakers were punished, but they stoutly denied their guilt, and appealed against their conviction. Mr. Johnson, the Government chemist, gave evidence to the effect that from the quantity of alumina found by him in the bread, he calculated that there was an addition of alum to it, to the extent of four grains to the pound. The cross-examining counsel attempted to show that the alumina had been introduced into the bread in dust, in the impurities of water and salt, and in potatoes. Mr. Johnson said he did not believe that it was the bakers who used the alum, for he had examined six samples of flour, and found alum in all, in proportions varying from eleven to twenty-eight grains to the pound. The judge allowed the appeal, and quashed the conviction in one case in which the amount of alum was so small as to make it possible that it was accidentally introduced, but affirmed the conviction in another case, where as much as eighteen grains to the pound was found.

### Edinburgh University Address.

THE Edinburgh University was opened by an address from Sir Alex. Grant, the Principal. This address was exceedingly interesting, but dealt largely in topics of a non-medical character, or such as most affected the alumni.

The encouraging position of the Medical Faculty was exemplified in the statistics put forth by the learned Principal:—

The increase which has taken place during the past year is chiefly due to the numbers which have joined the Medical Faculty. Everything tends to show the high estimation in which this Faculty is held. There have been 189 first entrances for the purpose of studying medicine during the past session. Of these 26 had previously attended other Scottish universities, 6 had attended English universities, and 7 foreign or colonial universities. Of the whole number it would appear that 98, or at least half, were foreign both by birth and residence to the soil of Scotland, and had come as pilgrims to a shrine of learning. Among the birth lands recorded we find 21 of the counties of England, Ireland, Wales, the Channel Islands, Malta, St. Helena, the Cape of Good Hope, Mauritius, India, Ceylon, Australia, Tasmania, Nova Scotia, Canada, the United States, the West Indies, South America, France, Germany, Spain, and Switzerland. And the record of schools points, in the cases referred to, to a previous domicile outside the limits of Scotland. This circumstance, while on the one hand flattering to ourselves, may, perhaps, on the other suggest some little deduction from the common boast that in Scotland, alone of all countries, one out of every thousand of the population comes under university education. If there be a considerable foreign element in the Scottish universities, that fact must be borne in mind in framing educational statistics for the Scottish people.

It is, in our opinion, of importance to the profession to see degrees in arts more commonly possessed by medical men. We have given prominence to the statements on this subject by the other Scottish University authorities, and we therefore invite attention to the opinions of Sir A. Grant, although we do not pretend to subscribe to them except partially.

### CURRICULUM IN ARTS.

The question still remains unsolved whether our curriculum for a degree in arts as at present constituted is not too rigid and inflexible and too little suited to meet the bent of different minds, and the different shades of requirement for various professions and walks of life. This is, it must be confessed, a very difficult problem for us. On the one hand, we have to meet the views of an exceedingly practical nation, whose tendency is to ask for tangible results and professional advantages in return for all the time and money spent on education. On the other hand, we are bound not to concede too much to such views, which are in themselves sometimes rather narrow and short-sighted. We have to stipulate for a sufficiently broad and liberal basis for all education which is to be stamped with a university degree; but with this proviso, I am still of opinion that the Scottish universities might do more than they have hitherto done to meet the wants of the nation—wants which seem to me to be proclaimed anew by every generation of our arts students. (Applause.) If there are any universities in which a fixed and exclusive arts curriculum might have been maintained, one would have said that the universities of Oxford and Cambridge would have been such; yet the degree system of Oxford and Cambridge, as compared with that of the Scottish university, is flexibility itself; while our curriculum, as compared with theirs, looks like a Procrustean bed, on which minds of all dimensions must be equally stretched. I have heard accomplished scholars declare

that they would not have taken our arts degree without much difficulty to themselves, owing to the amount of mathematics required. But again, many students come to us to whom the prospect of studying mathematics is the chief inducement, and who would be glad to be free of Latin and Greek after passing a moderate examination in these subjects. I find in our "First Year Book," though we do not ask for these details, that three students have entered their names as wishing to study "chemistry and natural philosophy," and one as wishing to study "chemistry and mechanical drawing." Such combinations of subjects evidently imply a desire of scientific preparation for different lines of professional life. Should they not, then, be encouraged, and at the same time regulated, by the University? The only means we have of encouraging and regulating such studies is to constitute them, with such additions as may be found advisable, into a degree curriculum. Whether this can be done, and how it can be done, are complex questions, on which I will not trouble you with any opinions. Facts, in the meantime, seem to indicate that if possible we should introduce more liberty of choice into our degree system. The extremest form of this kind of liberty is to be found in the German universities, where the student, after showing in his "Aliturienten examen" a competent knowledge of Latin, Greek, and elementary mathematics, is allowed to choose any two subjects he likes for his degree as Doctor of Philosophy. And of these two subjects he is expected to make himself profoundly master. Short of this total absence of all prescription of subjects many other systems might be mentioned, allowing the student more or less choice, if not at the beginning, at all events after a certain period of his career. But this is not the place to dilate upon them. I will only allude to one other result of the hard-and-fast curriculum in arts which is common to the universities of Scotland. The result of this system is not only to diminish the number of graduations, and to drive away arts students, who, under different arrangements, might have been induced to prolong their stay in the University, but also to cast a blight on those professorial chairs which remain outside the favoured circle. The class returns show that it may be taken as an axiom that no chair will permanently enjoy full vitality unless the subject which it teaches is available for degree examination. In saying this, I am reminded with satisfaction of the academical legislation of last year, which created a degree in engineering, and in the "First Year Book" I am glad to see that several of the entrants have recorded themselves as students of this subject.

#### Earth Closets.

THE earth-closet system of disposal of household excreta has been found to be practically impossible, in consequence of the bulk of the powdered mould which is necessary, the trouble and expense necessary for procuring it in towns, the difficulty of removing the resultant manure, and the impossibility of finding servants cleanly and regular enough to keep the apparatus clean and full of earth. Mr. Edward Stanford, F.C.S., has made to the mechanical section of the British Medical Association a proposal to substitute carbon in some form for the earth.

By the use of charcoal the amount of deodorizer required is reduced to less than a fourth as compared with earth, and by carbonising the manure removed, a constant supply is secured.

The quantity per head to be removed per annum may be fairly estimated at eight cwt., of which about seven cwt. represents urine alone. The amount of carbon required to perfectly absorb the whole of this quantity is less than eight cwt., so that in an ordinary household of ten persons, the total annual quantity required cannot

exceed four tons, and the whole removal will probably, owing to the drying action of the charcoal, be about five to six tons.

The carbon closets are also arranged to be quite automatic, and require no attendance from within. The charcoal is introduced through an aperture in the roof into a reservoir at the top of the house; a closet on each floor draws on this source of supply, and the whole of the product is discharged in a dry deodorised state into a cemented vault in the basement story of the house.

The reservoir need only be replenished, and the vault emptied, once a year. The manure removed can scarcely be distinguished from cinders by an ordinary observer, and it is equally inoffensive.

The value of the material removed is about one shilling per cwt., or eight shillings per head per annum. The household has the charcoal and the material removed without cost. A company called "The Nitro-Carbon Manure Company (Limited)," has been formed in Glasgow (Office, 154 West street, Regent street), to collect and treat the manure, and supply the charcoal.

#### New Books.

THE past month has been as prolific in medical books and new editions as November always is, and the book circulars devote large space to their enumeration. Dr. Allingham has brought out a small octavo on "Fistula and other Rectal Diseases;" and Dr. Anstie has published a somewhat more pretentious work on "Neuralgia and the Diseases which resemble it." Dr. Arthur Donkin puts on record in book form his views "On the Skim Milk Treatment of Diabetes and Bright's Disease."

"Gant's Surgery" is an immense work of thirteen hundred pages and nearly 500 wood engravings; and Sir James Simpson's book on "Anæsthesia, Hospitalism, and Hermaphroditism" will be read with equal interest.

Williams "On Consumption" is also out, and will, no doubt, take its place at the head of the standard works on the subject. New editions are issued of "Bowman's Chemistry," Matthew Duncan on "Fecundity and Sterility," Watson's "Practice of Physic," and W. H. Walshe "On the Lungs;" and Messrs. Baillière, Tindall, and Cox have turned out a fresh supply of the "Revelations of Quacks and Quackery."

From America we have Beard "On Stimulants and Narcotics," Hale "On Diseases of the Heart," Prince's "Reports on Plastics and Orthopædics," and Holden "On the Sphygmograph and the Physiology of the Circulation."

Among the smaller ware of the library table we find Budd "On the Bristol Epidemic of Cholera," Dr. Cholmely's "Inaugural Oration to the Medical Society," Wilson Fox "On Hyperpyrexia," Florence Nightingale's "Notes on Lying-in Institutions," and Dod's "Notes on Comparative Anatomy."

WITHIN a few weeks a man has been arrested in New York city for perpetrating an abortion on a woman, which killed her. He put her corpse in a trunk, and shipped it to Chicago. This rascal, who claims to be a doctor of medicine, formerly kept a large beer saloon, and about a year ago procured a diploma from a spurious medical college in Philadelphia for 100 dols., since which time he has been practising his profession of abortionist with wonderful success. Besides a house in Amity place, he had several others in different parts of the city, and a numerous corps of assistants.

DR. ROBERT ADAMS's well-known and much valued work on "Pneumatic Disease" is in the press of Messrs. Churchill for a second edition, which will be issued this session.

IN consequence of an outbreak of small-pox in Exeter, the local Board, with praiseworthy activity, have determined to erect a temporary hospital for the reception of cases forthwith.

By the latest advices from the Cape, the sudden death of Dr. James Abercrombie is announced. Deceased was an M.D., L.R.C.S., and L.R.C.P. Edin., and was universally esteemed in the colony.

SURGEON MAJOR J. P. BROUGHAM, M.D., has been permitted to retire from the Indian Medical Service on a pension of £550 per annum from Oct. 1.

AT Constantinople the cholera is alarmingly increasing. More deaths occurred on Saturday last than on any other day since the beginning of the epidemic. The weather is oppressive.

IN the Metropolis last week 1,400 deaths were registered, being 101 below the average. Of the deaths 61 were from small-pox, while those from bronchitis, pneumonia, and phthisis further rose from 315, 347, and 420 to 437 last week; these, however, only exceeded the corrected average weekly number by 14.

THE mails from India give us anything but a reassuring description of the health of some parts of that country. At Bushire, Bassidore, Decca, and Bunda Sungow, cholera has appeared, and is spreading most alarmingly. In the neighbourhood of Calcutta fever is raging with unusual virulence.

DR. ATHILL'S "Lectures on Obstetric Diseases," which we have been enabled to lay before our readers within the past summer, have been reprinted and issued in a form suitable alike for the student's text book and the library shelf.

ANOTHER case as to the competency of Hospital authorities to perform *post-mortems* upon the bodies of patients who have died under treatment, without the consent of relatives, is likely to come before the Court in a few days. The complaint is against the East London Childrens' Hospital, where the corpse of a child was mutilated against the express wish of the parents. In his summing up, the coroner condemned the practice severely, and recommended proceedings against the parties concerned.

THE first business meeting of the Medical Society of the College of Physicians, Ireland, will be held in the College Hall, on this (Wednesday) evening, when the following communications are set down for reading:—

- 1.—Dr. Grimshaw—"On the Prevalence and Distribution of Fever in Dublin."
- 2.—Dr. Eames—"On the use of Phosphorus in Diseases of the Skin."
- 3.—Dr. Hayden—"To Exhibit a Stethometer."

THE Editor of the "Irish Medical Directory" begs that those members of the Profession who have not returned the circular forwarded to them, or communicated details for publication, will kindly do so at once, and without delay. Most of those who have omitted to send back the return are, no doubt, under the impression that their names and qualifications will appear in the "Irish Medical Directory" in the same form as in the "London Directory." This is a false impression, for it is not possible for the editor to copy from any other work unless so specially instructed. The "Medical Register" is thus the only source of information at the disposal of the editor, and those who omit to afford the necessary information will have the dissatisfaction of seeing their names with no other appendage than their legal qualifications.

IN another place we have noticed the issue of many medical publications within October. We are promised still more to come in the course of the current season. Messrs. Baillière, Tindall, and Cox have in the press a monograph of Professor Morgan's, of Dublin, "On the Contagious Diseases"—meaning thereby venereal affections, a reprint of the valuable "Reports on Sewage and its Disposal," which have made their first appearance in our columns, and a work "On Food" from the able pen of Dr. Letheby. The Messrs. Churchill promise the Profession a "Handbook for the Laboratory," "A manual of Surgery" by Dr. Bryant, Dr. Risdon Bennett's new work on "Cancerous and other Intro-thoracic Growths," a book by Dr. Protheroe Smith "On the Mechanical Aids to Labour," a treatise "On Diseases of Women" by Dr. Barnes, a book "On Fracture" by Dr. Sampson Gamgee, and one "On the Functional Diseases of the Reproductive System" by Dr. Campbell Black, and lastly an "Experimental Investigation into the Action of Medicines" by Dr. Lander Brunton. Besides these monographs the same firm are to give us new editions of Dobell "On Winter Cough," Adams "On the Spine," Pirrie's "Surgery," and Lescher's "Elements of Pharmacy."

Messrs. Longman announce an abridgement of Pereira's "Materia Medica" by Bentley and Redwood, the second volume of Lane's edition of Cooper's "Dictionary of Surgery, and the Supplement to Watts's "Dictionary of Chemistry."

Lastly, Mr. Murray announces a book "On the Longevity of Man."

## SCOTLAND.

### NATURAL PHILOSOPHY.

SOME interesting statements were put forward at the opening of the Class of Natural Philosophy in the University of Edinburgh. We take a few of these from Professor Tait's Introductory Address.

In his preliminary remarks, he stated that the fundamental discovery of natural philosophy is that there can be no increase or diminution of the quantity of either matter or force. The laws of matter and energy, or force, are, the whole subject matter of natural philosophy. Professor Tait, gave instances of the necessity imposed on the student of natural philosophy of calculating distances of the largest as well as of the most minute dimensions. He dwelt on the fact that Sirius, the Dog Star, was 80,000,000,000,000, or  $8 \times 10^{13}$  miles distance from the earth, while in a single drop of water there are  $10^{26}$ , or 1,000,000,000,000,000,000,000,000,000 ultimate particles. He endeavoured to give the idea, presented by these incomprehensible figures by saying that each particle in a drop of water

is to the entire drop as the size of a walnut is to that of the earth. The sun, said Professor Tait, if placed in the position of Sirius, the nearest of the fixed stars, would be to us on this earth 400,000 of its present size—a paltry affair altogether inappreciable. The sun, in fact, is in size to the nearest to the fixed stars as is a walnut to the earth. He went on to illustrate the means we have of estimating the motions of the heavenly bodies. The Dog Star, Sirius, is receding from the earth at the rate of thirty miles a second. This star has been under the observation of men for 3,000 years. It has been moving away from the earth for all that time, and yet it has shown no diminution of size. So that in cosmical space, such a retreat—that is, about 2,839,659,120,000 miles since this star began to be observed, adding for the leap years—is as a drop in the bucket. The sun, said Professor Tait, is getting aged. A young star is bright and white. As the stars get older they become yellow and foggy. In their old age they are red. He showed that they sometimes in this latest stage blaze out with jets of hydrogen gas. A remarkable illustration of this had occurred lately in a star which had never attracted the attention of astronomers till it began so to blaze out. The sun is emitting such jets at present—some of them reaching as far as 70,000 miles, or nine times the diameter of the earth. Professor Tait proceeded to remark on the nature of nebulae and comets. He regretted that the great comet of 1858 had not been observed by any one through a prism, and said we should have to wait for another great comet to have the advantage which such an observation would bring. He said—It is all but established that a comet is merely a cloud of detached masses of stones, called meteorites, and as long as these stones are small we may plunge through as many comets as come our way, and we shall experience little or no harm. Our atmosphere is a protection against them so long as they are small; but if each stone were half a ton weight, the consequences of contact with a comet would be serious. The meteoric showers in November are simply results of the earth's passing through the tail of a comet. As to the appearance of comets, the tail is seen by reflected light, like the moon; but the head or nucleus shines by a light of its own, caused by the impact of its particles, just as the flint and steel produce light. The light of the nucleus is generally of a greenish or bluish tint. With reference to the nebulae, Professor Tait said the most recent observations seemed to establish that, at all events, the one studied by Mr Gill, of Aberdeen, was nearer to the earth than the fixed stars. This was important, as showing that Herschel's theory of the nebulae being of the same nature as the milky way was not according to the most recently observed facts. The nebulae observed by Mr Gill enlarged in size under observation, and this proves that it is nearer than the nearest fixed star. The lecture was concluded by an explanation of the difference between a wave and a ripple. The wave is the result of gravity the ripple is produced on the film or skin of the water, and does not depend on gravitation.

#### ROYAL COLLEGE OF SURGEONS.

At the Royal College of Surgeons, Edinburgh, the Introductory Lecture was delivered by MR. ANNANDALE. We take one or two of the more striking remarks from the able report in the *Evening Courant*.

Lectures properly selected and moderately attended are, in my opinion, most valuable; but the incessant lecturing of the times is wearisome to the student, harassing to the teacher, and not calculated to supply the best instruction. I would wish the student to have more time and greater facilities for study in the hospital—more time for work in the practical laboratories connected with physiology, pathology, and chemistry, and more time for practical instruction. In the various classes you are required to attend, you will receive advice as to the best methods of studying the particular subjects taught in them; so that I will only now offer you a few general remarks in connection with your future studies and position as medical students. Endeavour to devote some of your leisure hours to the improvement of your general education by a study of literature, art, general science, and the modern languages, for such studies form an excellent change of diet to the mind. Remember you are not merely working to pass examinations, but that you are preparing for the future practice of your profession. It is for this latter reason

that the course of practical studies is of such importance; and you cannot be too diligent in the wards of the hospital, in the dissecting-room, and pathological theatre. Such work will bring you true and sound knowledge, which will be serviceable all your lifetime. The mere acquisition of knowledge, and facts is not sufficient. You must learn how best to apply knowledge, so that it may be serviceable to yourselves and patients.

*Note-taking.*—The practice of taking notes is most useful, and its results valuable, provided you take notes of the right things in the right way. Don't take notes of what you can read with more advantage in print, but take diligent notes of any original observations of anything you do not understand (in order that you may master it at your leisure); and, above all, take careful notes of all you see and hear in the hospital. It is occasionally the sad experience of my colleague and myself to observe, and be helpless to prevent, the complete disgrace and ruin of a student who has joined us with bright prospects, but who instead of realising them, has given way to temptation, neglected his work, and brought himself to misery. You will all have temptations, many of them difficult to resist. Endeavour from the first to resist them, and their power over you for evil will soon become ineffectual; but once give way to them, and it will be difficult often impossible, to escape their effects.

"Motions to ill resist in their first grass,  
Lest, gaining growth, they shoot into the ear;  
Custom to sin at length will make you pass  
That for a bat which was before a bear."

Learn to respect yourselves and your profession, and in this way prove that you are worthy of your position. In your general intercourse with the public avoid as much as possible special professional conversation. Be liberal minded in the widest sense of the term; and if you wish to be happy in your future practice, avoid all tendency to what is termed gossip. To the patients who come under your care or observation in hospital or other practice fulfil the golden rule, and "Do to them as you would be done by." Ingratitude you may sometimes meet with, but if you honestly do your duty to them, you will receive many happy and pleasing testimonies of gratitude which will more than compensate for the former, and be real encouragement to persevere in your good work.

SIR ROBERT CHRISTISON, BART.—The honor which has just been conferred on Professor Christison is a graceful recognition of the position he has acquired as the representative of the medical profession and of science in Scotland. The expression of satisfaction which it has called forth evinces the universal respect in which his name is held.

EDINBURGH ROYAL MEDICAL SOCIETY.—The session was opened by an address by Dr. Andrew Wood, who dwelt on the undoubted advantages which this Society affords to the medical student.

The election of Lord Rector of Edinburgh took place on Saturday. The candidates nominated by the students were Sir Roundell Palmer and Sir W. Stirling Maxwell, when the latter was elected by a considerable majority.

FEMALE MEDICAL ELECTION.—A meeting of the senatus of Edinburgh University was held on Saturday, when a resolution was carried by a majority of 14 to 13 to the effect that the senatus represent to the University Court the propriety of rescinding their resolution and regulations in reference to the admission of women to medical education in the university, without prejudice, however, to the rights and interests of those ladies who have already entered upon their course of study, and without prejudice to the right of professors to give separate instruction to ladies in such classes as the University Court may approve.

## THE HAMPSTEAD HOSPITAL ENQUIRY.

## SPECIAL REVIEW.

(Prepared expressly for the MEDICAL PRESS AND CIRCULAR.)

## No. II.

As we read over the charges closing our last article, with critical eye, and by the light of more years of medical experience than these young medical practitioners have of life, and with no desire to depreciate the wisdom and skill which Mr. Aikman acquired in his few months' practice in a respectable Northern Hospital with its thirty-nine beds, we more than regret that an appeal should have been made at once to the general public Press—confessedly defective on all medical subjects—and not to the Profession and through the Medical Press first. The ordeal would, undoubtedly, have been more severe; the sensational part of these charges (for, alas! to withhold this term would only be to provoke it), and the hardly dignified egotism of the concluding paragraph, would have exposed the writers to some admonitory hints, but it would have saved a most painful scandal—and let us own that the Profession can ill afford at this critical juncture to amuse the world by evidences of its mutual recriminations and not very dignified jealousies. There is no allegation in the development of these charges that the medical staff was in any way disparaged, or oppressed by the Governing Body of this Hospital. There is not the faintest hint that the lay authorities overbore the professional—on the contrary, the Committee seem to have been sublimely ignored by these complainants, whose entire action has been aimed against their medical superior—in fact, the contest resolves itself into a professional quarrel. We do not say that there was no subject for an explanation; we do not urge that either party was wholly in the right or in the wrong; we do not say that authority may not have been assumed by Dr. Grieve, which Messrs. Aikman, Kynaston, and Greaves were beyond all warrant in protesting against; we do not even assert that there was an absolute unwisdom in appealing to the Press before appealing to the Managers (although that course would have been recommended by us in the first instance); but we do say that the contest should have been first waged in the pages of the Press exclusively devoted to professional matters, and for the following reasons: 1stly. Professional knowledge and experience would have stripped the charges of the mere *seemings*, and grappled with the substantial points at issue. 2ndly. The true interests of the whole Profession, in relation to all classes, especially the more suffering portions, would have been kept steadily in view. 3rdly. The actual balance of scientific opinion on the moot-points in these charges would have been faithfully rendered. 4thly. The public would have been kept steadily to the gist of the charges without being carried to all points of the compass by irrelevant and even ludicrous interpellations.

Let us remind these youthful aspirants to world-wide reputation that no impression of a lasting kind has ever been made on the public mind in relation to reform of medical or surgical abuse which has not been first sifted by the Medical Press; and we go still further, and say, it is impossible it ever should, whilst the ignorance on all great medical questions is so crass and so almost universal.

It serves but to illustrate our position when we read in a by-corner of the *Times* that a certain excellent maker of boots has made himself conspicuous by rushing headlong into this quarrel, and judging before the case was even heard out. No doubt the sympathy of a good bootmaker is very desirable: who that has felt the pain of corns could deny this proposition; but then, the witty line of the great lyric writer, "*Ne sutor ultra crepidam*," floats instantly to the surface of memory, when we find the excellent bootmaker's medical experience brought into competition with the best medical experts of our day. What we wish to enforce by this example is, that young medical men, beginning life, should look more to the approbation and judgment of those skilled and long-accustomed to great medical questions than simply to the ever doubtful and often dangerous impulsiveness of the unskillful and unlearned.

Every man has a right to be credited with good intention in his public and private acts, and yet, without collecting the evidence from which the intention is to be deduced by those who stand in the place of the jury, little or no reliable verdict can be given. The intention or *animus* of a man must be gathered, if you would form a correct idea of conduct. Hence, Mr. Aikman and his associates set forth the "intention" of "doing the State a service" in his proceeding; and, as this stands first in his letter, it must be grappled with. We turn, then, to the evidence by which this allegation must be tried. On Friday, Sept. 29th, evidence is produced of uncordiality of feeling between Dr. Grieve, the Medical Superintendent, and the young medical assistants, and Mr. Aikman states that he wrote the following placard to be stuck up in the sitting-room:—"Wanted, three active and unscrupulous young men, utterly devoid of any principles of honour. Applications must contain *cartes* and fighting weight, as the Superintendent (their medical superior officer) is a man of little physical, but immense mental power. All applications must contain previous experience with bullies, but strict secrecy as to the treatment of colleagues must be sworn to. These qualifications, with a total oblivion as to personal honesty, will be sure to secure the situation to the most enthusiastic applicant." We have, alas! another of these effusions, which, in fairness, we must give: "Wanted immediately, three active, intelligent medical officers for the Hampstead Small-pox Hospital. No one need apply who is not able to prescribe, dispense, and operate with the knife and fork, as the wittals is liberal, the wages good, and the lodging all found. Send *cartes de visite*, which will be returned unless good-looking. N.B.—Teetotalism preferred, as there has been a row about the beer." We do not think there will be great difficulty in gathering from these documents that the "intention" put forward by Mr. Aikman and his associates was not quite what is stated. He is not utterly free from impulsiveness of a more ordinary and less exalted motive—a bitterness and a want of that *reticence* which is characteristic of educated gentlemen glare out from these lines, not well in keeping with the exalted pretensions of the Assistants in their letter to the *Times*. We must not wholly pass over the vulgarisms which mar Mr. Aikman's evidence, and sadly jarred on the feelings of those who do not think slang stands profitably for sense and judgment. In answer to one of the Commissioners, who were anxiously inquiring about a child who had died of small-pox, and whose death the

witness appeared to attribute to lice beneath what he termed scabs, but to which cultivated medical men give the name of crusts, he flippantly remarked, with something of incongruousness with the solemnity he had assumed, that lice bred in a head covered with scabs "like one o'clock." Men on their oath, giving evidence wherein every word should be measured and weighed—when life or death is in balance, and the good to millions jeoparded—do not, if well advised, talk thus.

The moment we enter into a consideration of the charges we see how more than pertinent, how absolutely indispensable are the considerations with which we preface our analyses (see charges).

1st. "Delirious patients, more particularly children, tied down when their bodies were covered with eruption;" and

2nd. "Strait-waistcoats have been used with the same motive."

The ward 3rd, which was the adult female ward, in which Sister Caroline, Miss Harrison, and Nurse Jenkins were principally responsible for the nursing, is one of the wards on which Mr. Aikman bases his charges. "I do complain of the tying-down and strait-jacketing in that ward." Subsequently he states to Dr. Buchanan (one of the Commissioners), he "did not object to tying down in general, but he preferred the use of the strait-waistcoat." (See evidence, Sept. 20.)

It turned out in the evidence that not a few of the least controllable of our entire population were admitted to this hospital; some whose intemperate habits, in the widest sense, rendered them extremely difficult to restrain. They were of those whose delirium was often furious and sudden; and not unfrequently starting up from sleep they would exhibit great violence. Miss Harrison, who to a simple gentle manner adds wonderful courage and great experience in the treatment of the "brutal, blasphemous, and reckless class of our London slums and alleys," stated that not three men nor four men, nor any number of night-watchers could restrain such persons in their maniacal delirium without completely upsetting the repose of the whole ward. The appearance of men attempting to restrain such a patient led to determined and furious resistance and antagonism. She had to restrain by means of a folded sheet across the chest, and under one or both arms, the ends being fastened to the bedstead. This she had observed did not provoke the personal hostility which the hand restraint of persons produced. "Patients were (she observed), generally quiet when under restraint of a folded sheet, and it was the kindest treatment of them." It was elicited that she had offered her services to the hospital because those from the worst parts of London had been admitted therein. (See evidence, November 3rd). We do not quote any individual nor any number of men as settling the point. What the Chairman of the Board (Dr. Brewer) said in his evidence may be true, that medicine is peculiarly an uncertain science—more than law (in answer to Mr. Collins), inasmuch as there are no authoritative decisions of courts to settle moot-points in medicine; but we merely throw out for suggestion that Miss Harrison's long training and large experience entitle her to a fair hearing. Mr. Aikman's *first charge* with his and his colleagues' glossary, let alone the expressed opinion of medical men of great experience in the treatment of zymotic disease, is certainly one which ought first to have been ventilated in a professional or

scientific journal, and not thrust before the unskilful and unlearned merely to gain a point. When we come to charge No. 2 the case assumes a graver aspect. "Strait-waistcoats have been used with the same motive." It appears in the evidence that it was only at the urgent request of these very young men themselves that these strait-waistcoats were introduced into the hospital. "*With the same motive.*" We naturally ask what *motive*? These young medical assistants had obviously put these charges before the public as instances of the wanton cruelty of the managers and nurses of the hospital, and in that light they were regarded, as was proved by the monstrous illustrations which a sensational contemporary paraded in his weekly issue. But when the accusers themselves are giving evidence, protected with all that a very clever counsel can do to shield them from unpleasant disclosures, not only is all hint of *motive* absolutely dropped, but the charges become simply a matter of medical diversity of opinion, the accusers themselves making charges one way, and compelled by evidence to range themselves on the opposite.

It transpired that these medical assistants were each of them responsible for the entire medical treatment going on in their several wards. That restraint was a part of the treatment for which they were responsible. That each of them confessed the several nurses under each performed their duties to his entire satisfaction, and richly merited the encomiastic testimonials they had received. We conclude these remarks on charges *one* and *two* by reaffirming that without presuming to dogmatise about mechanical or manual restraint in the furious delirium of acute small-pox, we do unhesitatingly affirm this question was not one to be flung before the public in the way in which it has been, but it is better suited to the calm investigation and discussion of educated and scientific professors.

*The third charge.*—"Patients in an acute ward have been provided with a totally inadequate supply of milk and beef-tea for their use during the night."

Nurse Haynes, in support of this charge, says "she was not aware that there was ever too much milk in the children's wards, and that the overplus in the morning was handed over to the other wards. Sister Caroline was the sister (head nurse) in one of the wards I was in, and I complained to her of the beef-tea and milk being short once or twice." (See evidence Oct. 2nd.)

Sister Caroline, who was night superintendent from Feb. 7th to April 6th, and went *round the acute wards* twice every night, deposes, "Occasionally there was a deficiency of milk before I went on, but I always got an order for an additional supply, and the patients in these wards never suffered from want of beef-tea and milk. In the children's ward there was often more than was wanted." Again, "I had no difficulty in obtaining ice or barley-water when they were required." Nurse Haynes admitted that she gave or allowed the convalescents to take the milk, which was solely for the acute cases, and that the acute cases required incessantly drink. She had been cautioned by Sister Caroline not to do so; but says, "I had given milk to convalescents, and that was against my instructions, but I understood Mr. Aikman once ordered me not to give water." Again, "I am almost sure Mr. Aikman gave me instructions not to give water to patients." Mr. Aikman deposed (Sept. 20th), "I have no objection medically to children drinking cold water in small-pox." All the nurses called by the assistant medical officers state that they understood that

they (the nurses) were forbidden to give cold water to patients to slake their thirst in small-pox; and, strange, each officer denies that he either gave such an order or entertained such an opinion. Mr. Kynaston indeed thought the supply of milk in acute cases should be unlimited, which he did not suppose would either create indisposition or tend to create thirst, in however great quantities taken.

Thomas Jones, a patient, said, "He always wanted something handy to drink. He did not get enough to drink. He did not mean enough of milk, unless milk was the only drink. He only got three half-pints of milk a day, and one half-pint and a drink extra by night. This patient expressed that it was quantity of fluid which he wanted. He did not like the beef-tea, but he did like the milk, and got the nurse to substitute milk for beef-tea." This charge seemed subsequently to resolve itself into this: the milk ordered by the medical authorities was supplied in tin cans, which were marked by measured lines; that the quantity in the twenty-four hours was sent to the wards at two intervals, but that the distribution of the night's supply was not even. Mr. Aikman says he once knew the evening milk turn sour. "It was on a very hot night." The nurses of two or three wards depose to milk turning sour at or after midnight during very hot weather; but they had always beef-tea, water, barley-water, arrowroot, and toast-and-water at hand to supply the deficiencies. Dr. Jarvis deposed that the medical assistant officers were entirely responsible for the cases in their several wards "until they had drawn the medical superintendent's attention to them, and then there is a joint responsibility." Dr. Brewer considered that the diet, especially in the acute stage, is an essential part of the medical treatment, and that those responsible for the latter are responsible for the former also. Mr. Surgeon-Major Bostock, C.B., considered the diet of Hampstead Hospital a most liberal diet—the beef-tea as good and the arrangements as perfect as any in London. (The evidence of this witness in favour of the modes of restraint, and the general condition of the wards was clear, pointed, and very important, as it was on all the principal issues.)

Again, we have to deplore the crudity of the statement put forth in the charge three, as we did on charges one and two. If the question is on the subject of limited or unlimited supply of milk to acute cases, and on the mixing of milk with water in the course of the twenty-four hours, or of the best substitute if milk turns sour in the night—or if the question be whether the only test of sourness is litmus and turmeric paper, as one of these young medical assistants testified to the surprise of the more intelligent portion of the audience, surely in a scientific journal should this question have been first discussed. The third charge was certainly not sustained by the evidence, and the accusers have not gained confidence by it. The fourth charge being a simple iteration of the third, and not separately maintained, falls under the weight of the third.

*The fifth charge.*—"Complaints have frequently been made to us by both nurse and patients, that food supplied has been totally unfit for consumption."

We look in vain through the whole voluminous evidence before us for any substantiation of this charge save of the vaguest description such as any public institution in the Kingdom might be subjected to. Surgeon-Major Bostock, C.B., who deposes to frequent visits alone and with others to these wards, says: "I never heard any word of complaint. I saw the meat used in the wards at

Hampstead frequently, and inspected it, and I can say it was equal in every respect to what the Guards eat in London; the invalid's meat in the Guards is exactly the same as the other rations." (Evidence, Oct. 17th.)

Elizabeth Meredith, who was changed from ward to ward, stated: "It was the duty of the assistant medical officers to order the diet for the patients. She had not found the diets insufficient, and, after serving each patient, there was always some left for those who could eat more than others. She had once to notice in hot weather a leg of mutton being a little tainted in the vein; she complained to Dr. Grieve, and she served out cold meat. The patients eat the mutton for supper; and beef-tea was served out this same hot day instead of milk. (This nurse had received glowing testimonials of efficiency from the assistant medical officers). She never made any such statement as this (fifth charge) to Mr. Aikman; all such statements were without foundation." (Oct. 17th.)

Nurse Meredith was, she said, summoned on the side of Mr. Collins, the assistant medical officers' counsel. She had sufficient milk for her patients, but although sometimes milk was left over in the morning, this was not so often the case as with the beef-tea.

Nurse Manning states "the meat was always good and always eaten; it was never left. The beef tea was good and often preferred to milk by the patients. She remembered the patient Hatcher, who gave his evidence at the opening of the inquiry, and he told her he was going to see Mr. Greaves and Mr. Kynaston at a public-house in Wellington street, Strand. He promised to let her know what went on at Wellington street. Hatcher said he had nothing to complain of except the loss of a suit of clothes, and he was going to see the young doctors about that. 'All the clothes of the patients were always new when they could not be found.' She had written to Hatcher to remind him of his promise, for she thought it most ungentlemanly of the young doctors to go meeting people in public-houses on Sunday nights. Several respectable working men spoke of the meat in the Hospital as very good, and one or two expressed how happy they should be if working men could get as good in their daily employment when well. The contractors showed that the meat was of the same quality as that supplied to the clubs and other high-class London societies and institutions. One child complained that sometimes the meat got into and between its teeth, before it was changed for stew."

Dr. Bridges, Inspector of the Local Government Board, had visited the Hospital six times. He had inspected the food, and it appeared to him to be of good quality. He had spoken to individual patients, and all, with one exception, expressed satisfaction with their treatment: the exception was that of a man who complained that his nurse had drunk his wine. The case was inquired into, and the nurse was dismissed. [This freedom of complaint, which the patients enjoyed at least four times in every week (as the evidence testifies), and this summary redress of an ascertained wrong must not be passed unnoticed.]

Mr. Ernest Hart, who had gone round the wards with the Chairman of the Board (Dr. Brewer), and with Surgeon-Major Bostock, expressed satisfaction with the diet, which was generally better than that of similar institutions.

Dr. C. A. Gordon, C.B., Deputy-Inspector of Hospitals

in the Army, said the price paid for the meat was higher than that paid in the military hospitals.

Dr. John Murray, Visiting Physician of Middlesex Hospital and the Children's Hospital, Great Ormond street, acknowledged publicly writing a report setting down the charges of the Assistant Medical Officers as "childish and exaggerated," and his subsequent examination of the Hospital, in all its detail, confirmed him in that view of the charges under inspection.

We must leave charge five to take its fate. We do not believe anything would have been lost, but much every way gained, had this also been first sifted by competent professional investigation and comment.

Coming to charge six, we at once confess we approach it with a doubting mind. We have very little sympathy for the old morbid, half superstitious, half heathen sensationalism about the last minute of unconscious life. Some people still deem to atone for a life-long neglect by mere watching the last breath of their relative. Some pander to the vulgar predilection for a particular posture of becomingness—as if a child curved on the body of the bed died less decorously than one laid straight from pillow to foot. Charge six is simply that a child, in *articulo mortis*, was allowed to remain in a position in which it had become unconscious, and the nurse, seeing the doctor coming, hurried to her ward-room, and put on a clean apron; then meeting him, walked round the ward, and, coming to the dying child's bed, found it had, indeed, expired in the interval. Medical men will certainly not sympathise with the false, the morbid, and the mischievous—their mission is the diametrical opposite to all this.

The same censure applies to the seventh charge. A patient is said to have died at midnight, or thereabout. The nurse, finding the hot night oppressive in the ward, and that the body was offensive, gets the bed wheeled on its castors to the adjacent bath-room, and there it is deposited, covered with a sheet. Notice is given early the next morning (Sunday) and the assistant medical officers informed of the occurrence. One writes out a report to Dr. Grieve, but, "before it can be completed, the body is duly removed to the mortuary." If the dead body was acting prejudicially the assistant medical officers should have taken good care not to allow it to remain where it was, but themselves have engaged actively in its removal, either by authority or action; if it was only to point a sensational charge, it was a contemptible subterfuge.

This charge, too, would have been put in its proper place had Messrs. Aikman, Greaves, and Kynaston done what more experienced, and better informed, and higher in repute fathers in the Profession have done, and do, and must do, if they do not intend to bring medicine into contempt, viz., appeal to the Profession and to scientific knowledge to substantiate and investigate their alleged wrongs and charges against those who, by force of circumstances, happened to be placed over them.

The last charge about the loss of Elizabeth Bellue is totally imputent. The child has once before, it seems, been lost, and was subsequently found by its father in the Police Office. The Local Government Board are investigating into any defect of management which may have contributed in any way to this. In the meantime it appears by the evidence that the father of the child has expectations that if a proper reward be offered for the missing child, and if the neighbourhood of his own house be well searched to see if some parent or other person has not

the straying one, this charge, too, may turn out as ill-founded as the others. The charge of lousy heads was thoroughly gone into, and the suggestion that when the scab, as Mr. Aikman calls the crust of one child's head was removed, lice were underneath and the child died, is simply the confusion, moral or intellectual, or both, which science abhors.

Surgeon-Major Bostock says in his evidence, in answer to a question from one of the Commissioners, as to what he did with the lice found on the men in the Crimea, "Well, we all had them then." "And what did you do then?" "Well, we didn't write to the *Times* abusing the Commander-in-Chief."

Mr. Aikman also interpellated a case of contracted limbs, the blame of which he tries to throw on the general management of the hospital. (See evidence of child Stokes.) Mr. Bostock says, "I cannot understand a medical officer finding out a large bed sore of that character on the sacrum without knowing something of its previous history and character. I do not think the medical officer of the ward (Mr. Aikman), absolved from responsibility on account of such a bed sore because the nurse had not reported it; he should have looked out for it and anticipated its formation. In the then condition of the child, when the sores were formed, mechanical means to prevent contraction of the limbs would have been worse than useless. Mr. Aikman should have reported the case to the Medical Superintendent if even he had only reason to have anticipated a bed sore. Mr. Aikman should have found out the bed sores earlier, and their tendency to form on the sacrum. It is the practice in hospitals for a medical officer treating the patient to inspect the skin over the sacrum, and to make applications to prevent bed sores, for this is the most important part of the medical treatment." Sister Agnes had pointed out to Dr. Aikman the child Stokes lying in an unconscious state; it had a water-cushion to lie on; she had herself fed her every ten minutes. She showed Mr. Aikman the bed sores. Mr. Aikman never gave her (the head nurse) any instructions respecting the contraction of the child's legs, although she had pointed it out to him. She told Mr. Aikman she had tried to straighten the child's legs several times a day. Mr. Aikman, according to the whole evidence of this highly educated nurse, was hardly for a minute at Stokes' bed, even when his attention was specially drawn to the case by the nurse. The case of Sarah White had been most tenderly and assiduously watched and tended by the nurse.

In the charge of defective supply of linen, the fact seems to be that, although the laundry when adapted to the latest ascertained requirements turned out easily a thousand pieces a day in good order and fit for use, yet there was a time when, under the heavy pressure to which the hospital was subjected, that only by hard work and some grumbling the twenty-four laundry women could get through their task; and some heavy arrears at times disheartened the Superintendent of the washing department. There was a month "when the convalescents were not sufficiently supplied with changes of sheets and body clothes, although the acute wards were never suffered to be in want of either."

Thus, having gone over the charges, we come to the conclusion, as summed up by Messrs. Aikman, Kynaston, and Greaves. "Had we remained, we should have trusted to our own energies to have kept down mismanagement." We entertain very grave doubts on the subject on which these gentlemen express themselves so confidently. We think

neither their conduct, as exemplified in the *affiche* attached to the walls of their sitting room, which in any other rank of life would have been thought impossible; nor in their proved conduct of their several wards; nor in their conduct of their case; nor, in short, in any evidence produced before the Commissioners, are they warranted in assuming any such inference.

We shall investigate the charge respecting the lost child, Elizabeth Bellue, in a subsequent article.

## Literature.

### DISEASES OF WOMEN.\*

CLINICAL teachers of obstetric medicine and surgery are frequently asked, and as frequently hesitate to give, a decided answer as to the special treatise on the diseases of women they would recommend their pupils to study. The length, to say nothing of the expense of the many varied and able works on this subject, debar most students from adding any of these to their library during their educational career. Dr. Atthill, however, has come to the rescue and done good service by giving to the world a concise, lucid, and inexpensive treatise on the more commonly met with forms of uterine disease. His book consists of fourteen lectures, the substance of which was addressed to his class attending the Adelaide Hospital, and published in this journal at the time. In the first of these he explains the various modes of examining a patient in order to ascertain the disease she is suffering from. We are glad to find that our author does not rank himself with those who characterise the uterine sound as a "dangerous weapon," and as one never to be used save in the cases of the direst necessity, but, on the contrary, advocates its use in suitable cases, and points out in clear and terse language the mode of its employment. We do not hesitate to express our conviction, that had the late Sir James Simpson done nought else for science save to invent and recommend the use of this little instrument his name would have been rendered famous, and he himself characterised as a great benefactor to suffering humanity. In the second lecture leucorrhœa is largely discussed, and advantage is taken of the opportunity to condemn in the strongest terms the operation of clitoridectomy as a means of treatment for masturbation. It has been the habit of late years to utterly denounce this operation under every circumstance and contingency; we believe, nevertheless, that it is beneficially applicable for the treatment of some exceptionally rare lesions of that organ, and of conditions connected therewith, but we entirely accord our assent to the views expressed by Dr. Atthill as to its utter uselessness for the cure, or even alleviation of the debasing practice of which he treats.

Menstruation, and all its abnormalities, forms the subject matter of the next four lectures, and there is no part of this little work which we more strongly recommend to the perusal of the student than this, more particularly the chapters on menorrhagia. Special care is taken to explain the pathological lesion of *sub-involution*, a term but little known, and seldom met with, even in comparatively recent books. In his description of plugging the

vagina, Dr. Atthill has confined himself to the use of Ferguson's vaginal speculum. We wish mention had been made of the great ease with which this simple operation can be performed by using Marion Sims' duck-bill speculum, which to our mind seems equally, if not more applicable to the purpose. The author also has forgotten that the practitioner may be hastily summoned to a case demanding the immediate use of the *tampon*, when he may not have a speculum at his command, and has omitted to inform the student of any means of its introduction under the circumstances. We ourselves in such cases have been in the habit of adopting a simple and ever-ready plan—namely, introducing the first two fingers of the left hand into the vagina and applying them against its posterior wall, thereby affording a protection to the perinæum, and forming an inclined plane along which the plug—be it a pocket-handkerchief, or a piece of cotton, or a sponge, can be introduced without pain or injury.

Uterine polypi, fibrous tumours of the uterus, and ovarian cystic disease, are all ably treated of in the next three lectures; the various means that may be adopted for diagnosing the latter being clearly placed before the mind of the reader. In treating of the means usually employed for exploring the uterine cavity, our author discards the old and objectionable method of dilating that organ by means of sponge tents, and directs special attention and approval to those made of *laminaria digitata*. He here pays a just tribute to Dr. Kidd, of Dublin, whose modification of its use he strongly recommends, and in the ensuing paragraph accurately describes as practised by himself. He also bears ample and just testimony to the value of Dr. Barnes's india-rubber bags for the rapid dilatation of the cervix uteri. Much stress is laid on local blood-letting in cervicitis; we have in many cases employed this method of treatment, but our experience is not of so favourable a character as to adopt it to such an extent as Dr. Atthill recommends. Instead of the application of nitric acid to an inflamed surface the author advocates the use of a solution containing benzoic acid, tannic acid, and collodion. We ourselves have no experience thereof, but we think it merits a fair trial at the hands of obstetric practitioners. Cancer, and some of the various displacements commonly met with are the subjects of the remaining lectures, and which have met with careful consideration at the hands of our author.

To a work such as that which is the subject of this review, plates and illustrations, when properly and correctly finished, are invaluable; but we regret that in the present instance more attention was not paid to the delineation of the sketches before they were placed in the hand of the artist. In illustration of this we direct attention to Plate IV., which purports to represent a Hodges' pessary in position supporting a uterus that had been replaced after retroflexion; the uterus is certainly not lying in its normal position, nor is the pessary properly located *in situ*. Again, in the majority of the sketches illustrating the various obstetric operations, the bladder is represented as distended; this is objectionable, as the unwary student may thereby be misled into the dangerous idea that the evacuation of that scarcely demands his attention, whereas its imperative necessity before the commencement of any—even the most trivial obstetric operation, cannot be too strongly advocated. The limited space at our disposal prevents our alluding to many other points of interest in the work before us, wherein we have found so much to approve of and so little to condemn; but we cannot conclude without expressing our surprise and gratification that so much valuable information has been condensed into so small a compass; and we trust that the success of this, we believe, Dr. Atthill's first essay as an author (putting aside, of course, short detached communications) will be such as to induce him at some future time to fully complete that which he has so well begun.

\* "Clinical Lectures on Diseases Peculiar to Women." By Lombe Atthill, M.D., Univ. Dub., Fellow and Examiner in Midwifery, King and Queen's College of Physicians; Obstetric Physician to the Adelaide Hospital, Dublin; and formerly Assistant-Physician to the Rotundo Lying-in Hospital.

## Inventions.

### BARTH'S LIQUID NITROUS OXIDE GAS APPARATUS.

In this Apparatus, which appears to realise the extreme of portability, everything that is required for producing anaesthesia in short operations, is contained in a neat case, about seven inches square, by nine inches high.

The copper bottle, two inches by eight inches, containing twenty-five gallons of gas in the liquid state, weighs only 2 lbs. 1 oz. when full. A Catlin's bag and union, with Clover's double-valved facepiece, completes the Apparatus, and the whole may be easily carried in one hand.

### BROMATINE.

A PREPARATION of the Theobroma cacao, introduced by Messrs. Dunn and Hewett, of Pentonville. It is stated to be "absolutely pure, easy of digestion and assimilation," with the superfluous fat removed. We have not analytically tested this particular article; indeed, were we to lay ourselves open for laboratory examination for all the articles of diet, &c., introduced or brought out under a new name, a chemical expert would have as much as to fairly employ his time. But we have tasted the article in question, and find it agreeable to the palate, but would prefer for the sake of those whose stomachs rebel against fatty substances, to see a little more of the cocoa-butter removed, as is the case with Cadbury's and Van Houten's essences. Another preparation of cocoa and condensed milk by Messrs. Dunn and Hewett, which has now been before us several weeks, is a really excellent and convenient article for the sick room or for travellers.

## Correspondence.

### SNAKE BITES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—There is no effective antidote, not even alcohol or ammonia, against the stings and bites of these frightfully destructive vermin. There is nothing except to destroy them outright, as has been done in regard of wolves in most European countries. Let cobra heads, for example, be counted in payment of taxes, and these swarming reptiles would then soon be thinned to some purpose. The same procedure might indeed be adopted with regard to other poisonous serpents, and wild beasts as well. The best and safest way to deal with a venomous snake, is to shoot him outright. I saw them destroyed in this way in a moment in West Africa. In some places, as in America and Van Dieman's Land, they often pull serpents by the protruding tails from their lurking holes, and swinging them quickly round, dash them with force, so as effectively to crush them, against stone or tree. Prussic acid in milk would kill house snakes quickly, as most serpents will drink milk. Nicotine is poisonous to the whole tribe, but it is not easy to administer. Deer, swine, the mongoose, the abject ants, all destroy snakes, but man is able to destroy them best of all. Only set a money value on the heads of reptiles, increasing the value as they became scarce, and they would soon be found to prove comparatively harmless. No antidote could possibly efficiently avail, even if such a one were discovered, because it seems simply impossible that it should be always at hand when wanted. In other respects, the poison of most venomous snakes is so excessively rapid in its operation, as to leave little or no time for effective medication of any kind. In other respects, the thousands of per-

sons who, terrible to relate, are yearly destroyed in India alone by snake bites, prove the almost utter futility of the different proposed palliative appliances.

I am Sir, &c.

H. MACCORMACK.

Belfast, 26th October, 1871.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If the following case, which I believe to be of rare occurrence, possesses sufficient interest, you will kindly give it a place in your well-conducted paper. On the 27th of July last, I was summoned to attend Mrs. T., of Killyleagh, in her second confinement. On examination, I found the uterus well dilated, and the head presenting. She stated her belief that she wanted a month of the natural term. I was not more than an hour at the bedside until she was delivered of a female child, and certainly its appearance fully justified her statement, as it had all the look of a child between seven and eight months. Having been taken aside by a nurse-tender, I was about to apply the binder, which I always make it a point to do, in order that it may be in readiness to adjust when the placenta is removed, when to my surprise I found the abdomen still very prominent, and rightly suspected another child: I sat for two hours, expecting every minute a renewal of the labour; but there was not the slightest return of pains, notwithstanding repeated doses of ergot. I then left, and on the 30th (three days after) I was sent for hastily, and when I arrived, at 11 p.m., on examination I found the feet of a second presenting, with strong expulsive pains, and in half-an-hour she was delivered of another female child, the head coming away almost simultaneously with the shoulders, saving its life; inside of twenty minutes, two separate and distinct placentæ came away. Both mother and children are doing well.

R. J. SHEIL, M.D.

Killyleagh, Nov. 2, 1871.

### VACCINATION AND DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On the 23rd inst., I sent a letter to the *Irish Daily Telegraph*, in reference to one recently addressed by Mr. Hickson to that Journal. As the *Telegraph* has unfairly withheld my reply, may I ask you to publish it, a little altered but in no important particular. I wish to place on record a true statement of this Fermoyle vaccination case—so insignificant in itself—as anti-vaccinators may again attempt to press it into their service.

It pains me to have any controversy with Mr. Hickson, but I am bound to defend myself from his gratuitous attack conveying an unfounded charge.

I remain Sir, your obedient servant,

JOHN WILLIAM BUSTEED.

Castlegregory, October 30th, 1871.

*To the Editor of the Irish Daily Telegraph.*

SIR,—A friend has this day sent me the *Irish Daily Telegraph* of 17th inst., containing a report of some speeches delivered at an Anti-compulsory Vaccination Meeting held in Cork.

Mr. T. W. Corker in his speech, referred to a letter which appeared in the *Irish Daily Telegraph* some days before "from a gentleman in Kerry, stating that to his knowledge, not only an infant had been infected by the 'loathsome' infection, but the vile disease had been communicated to his mother." I do not deny that this statement so full of injurious insinuations, is the fair inference to be drawn from the letter referred to, purporting to have been written at "Fermoyle, Castlegregory," dated October 7th, 1871, and signed "R. C. Hickson." It was *there* that the alleged case of loathsome infection is said to have occurred, but Mr. Hickson has been in Dublin since September 1st, and has had no personal knowledge of the case. The real facts are very simple. On Sept. 13th, the child was vaccinated by me at request of the mother, with perfectly pure vaccine matter, taken by myself from a healthy child, and that infection was the product of other infection, which I had carefully transmitted from arm to arm, week after week, for six months, always with satisfactory results. On the 8th day after vaccination, I inspected the child's arm, and found the vesicle as perfect and characteristic as could be desired. On the 15th day I was at Fermoyle, at

Mr. Hickson's house, every inmate of which knew perfectly well the state of the child, and heard nothing as to illness of him or his mother, but being there again on the 22nd day, I was told that the child's arm had "festered" considerably, and that the mother having had a cut on one of her fingers, had with it touched the sore, that her arm had in consequence inflamed, but was then nearly well, and that it was not necessary for me to visit either mother or child. Now, sir, the fact is clearly that the child had rubbed its own arm and produced a sore, *perhaps* unusually severe, that the mother through inadvertence vaccinated herself, for which she may blame (or rather thank) herself and no other person, and the whole matter exhibits the recklessness with which anti-vaccinators make unfounded statements. I hope Mr. Hickson did not *mean* to insinuate that "vile" "foul" "loathsome" infection was conveyed to either mother or child, but his expressions may be and have been so interpreted. Fair play is a jewel, and these over zealous gentlemen ought to be careful not to asperse character, especially in ambiguous language, nor to impute "criminality" to persons who only seek to carry out what they are convinced is a most beneficent law in the kindest and most careful way.

I am Sir, your obedient servant,

JOHN WILLIAM BUSTEED.

Medical Officer, Castlegregory Dispensary.

Castlegregory, 23rd October, 1871.

## Medical News.

**Apothecaries' Hall, London.**—At a Court of Examiners held on the 9th instant, Messrs. George William Graham, of Winchester; Thomas Mayne, of Devonport; and Francis Seymour, of Odiham; having passed the necessary examinations, received the L.S.A. diploma:—Messrs. Alfred Edwards, of University College; William Edwin Griffith, of the Middlesex Hospital; William Thomas Hawthorn, of the London Hospital; and George Woodward, of St. George's Hospital; passed the primary professional examination.

**Hampstead Small-pox Hospital.**—Yesterday (Tuesday) a deputation from the Hampstead Hospital Removal Committee waited upon the Right Hon. James Stansfeld, President of the Local Government Board, to urge the importance of removing the present "temporary" hospital sheds at Hampstead at the earliest possible opportunity, and the unsuitableness of the site for a permanent hospital for contagious or infectious diseases. The Hampstead Vestry have also resolved to memorialise the Local Government Board and Metropolitan Asylum District Board against the erection of additional hospitals for the reception of cholera patients.

**The Legion of Honour.**—We are informed that the French government intend to bestow this honour, or have already done so, upon Mr. MacCormac, F.R.C.S.I., late of Belfast, and now assistant-surgeon to St. Thomas's Hospital, for his meritorious services as surgeon of the ambulance during the war.

**Advantages of Vegetarianism.**—We stand an excellent chance of being educated for the millennium between societies for the suppression of alcohol, of tobacco, of Sunday trading, of public amusements, of flesh meat. The sort of mirror of chivalry and example of everything noble in human nature who would be the product of a joint operation on a single creature of these remedial confederacies, strikes the imagination with envy and wonder. No wine, no pipe, no theatre, no sinful soup or cursnaring hash for him. He eschews light conversation. He has been early married, and has an immense family; both vegetarians and enrates being invariably the possessors of fruitful vines. He entertains with slops and watercress. —*Globe.*

**Variella in San Francisco.**—Chicken-pox has prevailed lately in this city in an aggravated form, some cases so near to small-pox in character as to have been reported as such to the Board of Health.—*Pacific Medical and Surgical Journal.*

**Alleged Neglect of a Patient at King's College Hospital.**—In our last we mentioned that the coroner's inquest had been adjourned in order to procure the attendance of Mr. Roche;

we now give this gentleman's explanation of the alleged inhuman treatment which was offered before the coroner's court on Thursday last. Mr. Roche stated that the man spoke to him while he was dressing the wound, and at that time presented the appearance of having sustained only a slight shock, not serious enough to be taken into the hospital. He told the men who brought him to take him home, put him to bed, and keep him quiet. The men urged that he was only a poor potman, but he did not think that a sufficient reason for admitting him. When he was afterwards admitted witness did all that was possible for him, but he died during the night. Cross-examined by the coroner, witness said deceased was certainly not insensible when first brought to the hospital, nor did the men tell him that deceased had been so. There being no indication that any fatal result was likely to follow, he considered himself justified in refusing to admit the deceased. The Coroner summed up the evidence at great length, and said the case was of great importance, both to the hospital and to the friends of the deceased. After some deliberation the jury returned a verdict of "Accidental death," the foreman at the same time handing to the Coroner the following written document:—"From the nature of the evidence and the symptoms apparent at the time the patient was brought to the hospital, in his inability to walk, and his state of partial insensibility, it is the opinion of the jury that it was an urgent case for admission to the hospital; and it is to be regretted that Mr. Roche, the house-surgeon, turned him out in defiance of the remonstrance of the persons who brought him, thereby lessening the chance of the poor lad's recovery." The proceedings then terminated.

**Metropolitan Asylums Board.**—On Saturday there was a very fully attended meeting of the members of the Metropolitan Asylums Board, Dr. Brewer, M.P., the chairman of the Board, presiding. A report was received from the committee of the Leavensden Asylum, in reference to a communication from the Local Government Board read at the previous meeting, intimating that there were a number of patients in that institution who did not strictly come within the scope of its operations. The report stated that during the past fortnight thirteen patients had been received, eight had died, and twenty-four had been discharged, leaving 1,613 in the asylum. Of thirteen patients discharged, nine were sufficiently recovered to be returned to the workhouses, or their own friends, and four to a county asylum. As to cases of dangerous and curable patients, steps had been taken as required by the Local Government Board, to transfer all to the proper hospitals. Two commissioners of lunacy had visited the asylum, and directed that five males and eight females should be moved to county asylums; but the committee were at a loss to understand upon what grounds the commissioners had made this selection, as these patients were reported by the superintendent to be perfectly harmless, and fit to be retained in the asylum, and this had since been supported by the medical superintendent of Colney Hatch—that four out of the five males sent there were of the chronic imbecile class, and ought not to have been sent there for any lengthened period. Under these circumstances the committee did not propose to take further steps till they received instructions from the Local Government Board. The report from the Hampstead Hospital Committee was an interesting one. During the past fortnight 126 fresh cases of small-pox have been admitted, sixteen have died, and sixty-one been discharged, leaving 190 under treatment, as against 141 at the date of the last report. The total number treated up to the present time has been 5,822, of whom 1,089 have died, and 4,543 have been discharged. It will thus be seen that the number of fresh cases has been 80 per cent. higher during the past fortnight than in that preceding, and has exceeded the vacancies caused by discharges and deaths, by forty-nine. This, the committee state, has rendered necessary the immediate reappointment of a second assistant medical officer. The committee feared that from present appearances the whole of the accommodation which can be afforded, will be called into requisition during the whole of the forthcoming winter. The report of the Dreadnought Hospital Ship Committee showed, that, as it seemed very improbable that cholera will appear in London for some time to come, they had felt it desirable to give notice to the medical and other officers that their services would be dispensed with, which would reduce the expenditure by upwards of £30 per month. This report was also approved. Reports were also presented to the board from the committees of the Caterham Asylum, the Stockwell, and other hospitals.

### NOTICES TO CORRESPONDENTS. INNOCENT ADULTERATIONS AND THEIR RESPONSIBILITIES.

To the Editor of "The Medical Press and Circular."

Sir,—Permit me to correct an error in the copy of my letter on the above subject, at page 425 of last week's MEDICAL PRESS AND CIRCULAR, in which I am made to say, "that in my view, innocent adulteration is not a fraud, and may be tolerated as long as it is noxious to health," whereas it should have been, "as long as it is not noxious to health."

I remain, yours, &c.,  
HENRY LETHBY.

17 Sussex place, Regent's park,  
Nov. 11th, 1871.

Mr. STREAD.—Received with thanks.

Mr. BLACKETT.—Sorry we cannot give you the information.

Mr. J. L. MILTON.—We have not received the communications referred to.

Dr. H. STANLEY GALE, Manchester.—Your paper "On the Relief of Pain by the Constant Galvanic Current," received.

The Rev. W. A. AYTON, Tamworth.—No former communication for back numbers of the Journal was received from you.

### BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

The Treatment of Pulmonary Consumption. 2nd Edition. By J. Henry Bennett, M.D. London: J. and A. Churchill.

The Clinical Uses of Electricity. By J. Russell Reynolds, M.D., F.R.S. London: J. and A. Churchill.

Essentials of the Principles and Practice of Medicine. By Henry Hartsborne, A.M., M.D. Philadelphia: H. C. Lea.

The Treatment of Skin Diseases. By Robt. Liveing, M.D. London: Longmans.

A New Ovariotomy Clamp. By B. F. Dawson, M.D., New York. New York Medical Journal; Nature; The Medical Cosmos.

### VACANCIES.

Royal Free Hospital, London. Junior House-Surgeon. Board and residence free. (See advt.)

General Hospital, Birmingham. House Governor and Secretary. Salary £200 per annum, with board and residence.

Derby County Lunatic Asylum. Superintendent Physician. Salary £100 per annum.

South Staffordshire General Hospital, Wolverhampton. Assistant Physician. Salary £100 per annum, with board and lodging.

Chorlton Union. Assistant Resident Medical Officer. Salary £120, with residence.

Westhampnett Union, Sussex. Medical Officer. Salary £100.

Royal Infirmary, Edinburgh. General Superintendent. Salary £420, with £80 for house.

St. Marylebone, Middlesex. Medical Officer. Salary £100.

Charing-cross Hospital. Junior Surgeon Dentist. Honorary.

Evelina Hospital, London. Medical Registrar.

Mountmellick Union, Coolrain. Medical Officer. (See advt.)

Carrickmacross Union. Medical Officer. Salary £30. (See advt.)

Enniscoorthy Union. Medical Officer. Salary £90. (See advt.)

### MEETINGS OF THE LONDON SOCIETIES.

Wednesday, Nov. 15.—SOCIETY OF ARTS, 8 P.M. Opening Address by Lord Lennox.

Monday, Nov. 20.—MEDICAL SOCIETY, 8 P.M. Ordinary.

### APPOINTMENTS.

BERNARD, A. M.B., Medical Officer to the Workhouse Infirmary, Liverpool.

CHIENE, J., M.D., Assistant Surgeon to the Royal Infirmary, Edinburgh.

CUMBERBATCH, A. E., M.R.C.S.E., Surgeon to the Metropolitan Dispensary, Fore street.

HIGGS, T. F., Medical Officer for the Dudley Union Workhouse.

HODGES, F. H., L.R.C.P., House-Surgeon to the York County Hospital.

HOWSE, H. G., M.B., F.R.C.S.E., Surgeon to the Evelina Hospital for Sick Children, London.

KNOTT, M. O'M., L.R.C.P.Ed., L.R.C.S.I., Surgeon to the Co. Mayo Infirmary, Castlebar.

MILLS, S., M.R.C.S., Surgeon to the E Division of Metropolitan Police.

NEAL, B., L.E.C.P., L.F.P. & S. Glas., Assistant Medical Officer to the Cornwall Lunatic Asylum, Bodmin.

ORCHARD, T. N., M.B., C.M., Senior House-Surgeon to the Ardwick Dispensary, Manchester.

ORWIN, Mr. A. W., Resident Accoucheur to Charing-cross Hospital.

READ, C., M.R.C.S.E., Resident House-Surgeon to the Royal Orthopedic Hospital, London.

SAVORY, Mr. A. H., Resident Medical Officer to the Charing-cross Hospital.

SLACK, G. F., M.R.C.S.E., Resident Surgical Officer to the Charing-cross Hospital.

SMITH, A. W., M.B., M.R.C.S.E., Senior House-Surgeon to the Preston and County of Lancaster Royal Infirmary.

STEELE, J. W., M.D., Medical Officer to the Workhouse Infirmary, Brownlow hill, Liverpool, vice James Ridley, L.K.Q.C.P.L., L.R.C.S.L., appointed to District No. 2.

SUTHERLAND, J., M.B., C.M., Junior House-Surgeon to the Ardwick and Ancoats Dispensary, Manchester.

TAYLOR, M. H., M.B., C.M., Assistant Medical Officer and Dispenser to the Hampstead Small-pox Hospital.

### Marriages.

ATKINSON—DALY.—On the 8th inst., at Holy Trinity Church, Hull, the Rev. H. S. Atkinson, B.A., to Elizabeth Frances, daughter of Dr. O. Daly, F.R.C.P.Lond., and J.P. for the East Riding of Yorkshire.

NIXON—BLAKE.—On the 6th inst., at Booterstown, Dr. Nixon, of Westland row, Dublin, to Mary, daughter of the late Dominick Blake, Esq.

OTTERBOURG—COHEN.—On the 6th inst., at Dover, Solomon Otterbourg, M.D., Chevalier of the Legion of Honour, &c., of Paris, to Theresa, daughter of the late Rev. R. J. Cohen.

PERKINS—BANNISTER.—On the 7th inst., at All Saint's, Hessele, East Yorkshire, Thomas Perkins, Surgeon, of Snaitth, to Polly, daughter of Anthony Bannister, J.P., of Kingston Lodge, Hessele.

### Deaths.

BUTLER.—On the 1st inst., at Sherfield Court, Hants, W. Butler, M.R.C.S.E., aged 23.

HANCOCK.—On the 6th inst., at Wedmore, Somerset, John Hancock, M.R.C.S.E., aged 61.

HAWKINS.—On the 3rd inst., John Hawkins, M.D., of Woodstock, formerly of Laugharne, Carmarthenshire, aged 87.

WILLIAMS.—On the 5th inst., Caleb Williams, M.D., of Micklegate, York, aged 73.

LIGHT, DELICATE, PALE SHERRIES.—A great and beneficial change has already taken place in the habits of our upper and middle classes by the more extended introduction of a variety of light wines of varied and unimpeachable dietetic value. The reduction of the wine duties has been a great boon, as not only has it had the effect of doubling the consumption of wine within the short space of ten years, but it has made light wine—what it should undoubtedly be—an article of daily and ordinary consumption, and far less liable to be taken in excess than when wine was a highly stimulating and costly luxury. At the present time the facilities for obtaining cheap and wholesome wines and other stimulants, bearing the guarantee of large and respectable dealers, in almost every town and village, is an advantage which deserves to be kept in view. Cheap wine has no doubt a certain amount of prejudice yet to overcome, and the medical man may do much in assisting to dispel this. Cheapness in wine does not necessarily argue a deficiency in stimulating and nourishing qualities, still less unwholesomeness. In our issue of January last we touched upon the article Sherry, and drew attention to the important place occupied by Spain as a wine-producing country. Since that time we have continued to use opportunities of testing and comparing the relative qualities and prices of various Sherries offered for sale, and have been especially struck by some light, delicate, pale Sherries obtained from the Messrs. W. & A. Gilbey. We think it due to the commercial enterprise, and a fair recognition of the undoubted benefit which this firm has conferred upon medical patients in the introduction of sound wholesome wines at moderate prices, to say that some of these Sherries approach nearer to our idea of what a good, generous, stimulating wine should be than anything we have seen for some time past, while the price places them within the reach of all when required for medicinal and dietetic purposes.—[British Medical Journal.]

## LECTURES ON EPILEPSY

DELIVERED IN THE

### LEDWICH SCHOOL OF MEDICINE,

BY HENRY EAMES, M.D., Dub. L.C.P., &c.

Physician to Mercer's Hospital, Joint Lecturer on the Practice of  
Medicine, Ledwich School, &c.

(Continued from page 431.)

THE convulsions are of great violence, as has been already said. They commence in the neck, and the head is generally drawn to one side, and slightly backwards. The thoracic muscles and those of the extremities are quickly involved. The chest is as though pressed upon by a heavy load, or held in a vice, and partial asphyxia is the result. The non-aeration of the blood is shown in the bluish tint of the cheeks and lips. The spasmodic muscular contractions are sometimes of such violence as to cause spontaneous dislocations. You will recollect that the convulsions may be unilateral throughout the attack. Frothy saliva mingled with blood rests on the lips, and blood may burst from the nose and ears. In severe cases of the disease you may observe about the eyes and forehead numerous small blood extravazations, ecchymoses, in the rete mucosum of the skin.

The feces, with flatus and urine, are often expelled during the fit. The penis may become erect and the semen be discharged. The pulse at the wrist is generally small and irregular, and at times is hardly perceptible. The carotids pulsate violently. The action of the heart is tumultuous, becoming more regular towards the end of the fit, when the ventricular contractions often fall in frequency below the normal rate.

All through the attack consciousness is completely abo-

lished. You may cut or burn the patient without hurting him. According to Romberg reflex action is not abolished during the seizure. The eye is closed if the conjunctiva be touched, and there is wincing if cold water be thrown on the face. This is true at least of milder forms of the disease.

As the fit is passing off the convulsions subside. Fœtid and clammy perspirations break out on the head, neck, and chest. Deep sighing inspirations are heard, and subsultus replaces the spasms of the muscles. The sufferer is not at once restored to the use of his mental and bodily faculties. He remains in a soporific, almost comatose, state. His respirations become gradually easier and freer. He presently sits up, speaks a few words with faltering voice, complains of headache, pain in the neck, occiput, or any parts he may have hurt in his fall, and after a longer or shorter interval is restored.

Epilepsy occasionally confines its attacks to the night time, then termed nocturnal epilepsy. The patient may know that he has had a fit only by finding in the morning his tongue sore and bitten: or his bed polluted by feces, urine, or semen. Dislocations unexplainable on any other hypothesis than that of epilepsy may at the same time occur. The bones most frequently dislocated are the lower jaw and the humerus. The teeth are also occasionally fractured.

This disease is recurrent; that is, if an individual has had one attack of epilepsy, it is strongly presumable that he will have other attacks. The frequency of the fits varies greatly. The *petit mal* recurs much oftener in a given time than the *grand mal*. Ten times in one hour the epileptic vertigo may return; however, one or two attacks in the twenty-four hours is more common; and, more usually still, a much longer interval elapses. The *grand mal* is less urgent in its attacks, but each access of this form is incalculably more severe. Occasionally it happens that one attack rapidly succeeds another; the two or more—sometimes

many—constituting what is termed a paroxysm, or the status epilepticus. When you hear of epileptic fits having lasted for hours—nay, or even days—you will understand that you are dealing with this status epilepticus; for, I repeat, that the true isolated attack rarely endures longer than four minutes, an attack of six minutes' duration being very uncommon. When the status epilepticus is fully established, death is usually the result. In the convulsive form of epilepsy—the *grand mal*—there are generally considerable intervals of time between the fits. A year or six months may intervene between each attack. Unless in severe cases, the interval will not be less than a month or two. It is said by some authors that nocturnal epilepsy is a more redoubtable form of the malady than that in which the fits occur by day. Some cases, however, in which the attacks come on indifferently by day or night, have under treatment been converted into the purely nocturnal variety. This is generally to be regarded as a good prognostic sign, and is very grateful to the patient, rendering his evil case more tolerable.

Now, gentlemen, this disease is frequently simulated, either for the purpose of exciting sympathy and deriving profit therefrom, or by soldiers to obtain their discharge, and also by others for various purposes, so that it behoves you to understand how to distinguish the real from the simulated malady. The following facts will enable you to do so:

The true epileptic makes no preparation for his fall. He frequently falls, too, as you have been told, on his face, and his forehead, nose, cheeks, and chin bear the marks of former wounds. The simulator of the disease chooses the place in which to fall, and takes care to have an audience. He never falls into the fire, or where he may be seriously injured. He takes care to guard his face by throwing out his hands. He has no scars of former wounds. The countenance of the epileptic has something peculiar about it if the disease be of long standing. The features are coarse, the eyelids and lips are swollen, the look is faltering; the most beautiful face will in time become thus deformed. The traces of the puncta ecchymotica may also be observed. At the moment of his fall, the true epileptic is of a deadly pallor. This cannot be simulated. The contractions of the muscles of even a delicate subject are so strong that they resist the united strength of two or three bystanders. An impostor can of course call up only his normal force. The eyes in a true fit are half open; the eyeballs rolling convulsively are distinctly visible. The pretender usually keeps his eyelids closely shut. The pupils are fixed, and do not contract under the stimulus of light. The pulse is generally irregular. These cannot be simulated. The surface of the body is cool. An impostor will be sweating at every pore from his exertions. A pretender will rarely bite his tongue. He cannot make his nose to bleed, nor can he void his feces or urine; nor will his penis be erect. A person in a true fit is absolutely unconscious and insensible, hence feels no pain. Hot sealing-wax dropped on him, or a red-hot iron touching him, causes him no uneasiness. It is otherwise with the pretender. The police force have a ready means of detection, which consists in violently pushing the thumb-nail under that of the person in the fit. This proceeding causes acute suffering if insensibility does not exist. Sir Thomas Watson's suggestion of desiring in the patient's presence boiling water to be poured over his legs, and then actually to pour cold water, is an excellent and practical one. This will not injure a real sufferer, whilst an impostor would almost certainly betray himself. The pretended fit is generally over-acted; and again, it lasts too long. The true fit rarely exceeds four minutes, and is commonly shorter. The aura especially is usually over-done. Impostors use it as the drum or bell to collect their audience.

The convulsive seizures of hysteria—that Proteus of disease—often simulate very closely the attacks of the *grand mal*. It will frequently require the exercise of your nicest discrimination to determine with which of the two maladies you are in contact. At other times the diagnosis is sufficiently easy. The globus hystericus, also called the aura hystericæ, bears some analogy to the aura of epilepsy. It

consists, as I dare say you know, in the sensation of a ball, or some foreign body, rolling about in the epigastric or umbilical regions, which presently passes up the œsophagus and arrests itself behind the larynx, giving rise there to a feeling of strangulation. This is due to spasmodic contractions of the muscular fibres of the œsophagus passing from below upwards. Now this is different from the epileptic aura, and is always of much longer duration, the aura epileptica passing on its course with lightning speed.

The epileptic desires solitude, and, having uttered the initial shriek, remains silent. An hysterical girl will fling herself from side to side, tossing about her arms, struggling with those holding her, grinding her teeth, foaming, and possibly crying aloud every half minute. This is a contrast to the epileptic. The convulsions of hysteria, with rare exceptions, affect both sides of the body; those of epilepsy commonly affect but one, or one principally. The countenance of the hysterical is also widely different from that of the epileptic. The history of the case will also be an important item in leading you to a correct diagnosis. I remember being told one morning on coming into the hall of the hospital that there was a fearful case of epilepsy in my wards. On inquiry, I learned that the fits were continuous since her admission the previous evening. Arriving at the bedside, I found a young woman of eight-and-twenty foaming at the mouth, her hands clenched, her limbs convulsed, and screaming aloud. On examining her I recognised a former patient, who had been under my care with hysteria simulating peritonitis. I quickly allayed the apprehensions of those around her, and engaged to terminate the fits. I directed some buckets of cold water to be fetched, and announced my intention of drenching her therewith. On the mere announcement, the convulsions began visibly to decline in violence, and presently ceased. She then said I had mistaken her disease, and requested her discharge. The prolongation of the convulsions in this case was contra-diagnostic to epilepsy. It need hardly be mentioned that these hysteric convulsions occur almost invariably in females. Hysteria and epilepsy may co-exist, and then the diagnosis is surrounded with difficulty. However, such cases are of very rare occurrence.

It is held by many authors that no very definite line of distinction can be drawn between the convulsions of epilepsy and of eclampsia. This is undoubtedly true of what is termed symptomatic epilepsy or fits, occurring in a person affected with a cerebral tumour, whether syphilitic, tuberculous, or cancerous. Some would to such, and as I think properly, apply the term eclampsia. The convulsions so frequent towards the close of Bright's disease are by some considered epileptic, by others eclamptic. The latter seems the more correct view. A woman in the latter months of her pregnancy becomes subject to convulsive seizures, recurring very frequently at short intervals—perhaps many times a day—and which ceases entirely on the birth of the child. Here we are dealing with eclampsia. Except in the status epilepticus such frequency of the fits is not observed, and epilepsy once established would be likely to remain, despite the birth of the child. An immediate fatal result is much commoner in eclampsia than in epilepsy. This latter very rarely causes death in its first seizures, the former frequently does. Thus the immediate prognosis of eclampsia is worse than that of epilepsy, whilst the ultimate result is much more favourable. It has however been observed that many children who are subject to convulsions, that is eclamptic, become towards adolescence epileptic. This shows the close connection between the two diseases. Epilepsy generally strikes those apparently in the enjoyment of perfect health, and without premonitory symptoms. The aura passes, and he falls. Eclampsia occurs in those of broken health, or in those in whom you may find a predisposing cause, such as renal disease, syphilis, pregnancy, &c. Should in such a case the convulsions recur with frequency, you may pretty safely assume that they are not epileptic. The close resemblance of the phenomena of the seizure in both maladies always tends to obscure the diagnosis.

(To be continued.)

CLINICAL LECTURES  
ON  
DISEASES OF THE EYE,

DELIVERED AT THE ADELAIDE HOSPITAL.

By H. R. SWANZY, M.B., L.R.C.S.I.

Ophthalmic Surgeon to the Hospital, and Surgeon to the National Eye and Ear Infirmary; late Assistant to the late Professor Von Graefe, Berlin.

LECTURE I.—*Glaucoma.*

GENTLEMEN,—The disease from which this patient is suffering in his right eye is called glaucoma, and there are few diseases to which the flesh is heir, more important for you to be well acquainted with, than it. Most of you spend much time in studying the signs and symptoms of stone in the bladder, and the various modes of treating it; while, in the course of your practice afterwards, it may very well occur that but few of you will ever come across a case of the kind, and still more possible that none of you will ever be called upon to treat such a case. On the other hand, glaucoma is a disease of which, whether you practice as physicians or surgeons, at home or abroad, you are almost certain each of you to come across one or more cases in the course of your practice. The great importance of being able to recognise the disease, depends upon the fact that, if left to itself, it is certain to lead to absolute blindness, but if the proper treatment be applied in good time, 90 per cent. of these eyes may be saved. The patient before you is hopelessly blind of the right eye, for he can with it no longer distinguish light from darkness. Until six months ago he could do so, and if the treatment, of which I shall speak directly, had been then adopted, he would now have some use of the eye. This is the third case, which has come under my notice in the same condition, within the present year. In one of the other cases the disease had produced complete blindness in both eyes.

Now, in what does this disease consist? It consists in an increased tension within the chamber of the vitreous humour, possibly a hypersecretion of the vitreous itself. What it is which gives rise to this hypersecretion, if such it be, has not yet been discovered, although numbers of experiments have been made on the subject, and theories without end propounded. The simple known fact however, is, that glaucoma consists in an increased tension within the chamber of the vitreous humour, or, as we more commonly say, an increased intra-ocular tension.

You may recognise the increased tension in the present case, as in all others of the disease, by palpation of the globe of the eye with the tips of your two index fingers, when you will find the affected eye much *harder* than the normal globe. In making this examination, I think it is well to support the 2nd, 3rd, and 4th fingers of each hand on the patient's brow over the eye, desiring him to look down at the same time. The pressure you apply to the globe must of course be very gentle, and it will be well for you at first to practice palpation of the globe on yourselves and your friends, so as to form an estimate both of the amount of pressure which you should exert, and of the average tension of normal eyes.

There are two chief forms of glaucoma, namely, simple and inflammatory. Our patient labours under the latter form of the disease.

Simple glaucoma destroys vision very slowly indeed, such a case often lasting two or three years. It is unattended by pain, and the only signs of the disease on the exterior of the eye are usually a few rather engorged episclerotic veins, a shallow anterior chamber (in consequence of the pressure in it being less than in the vitreous humour), and a sluggish pupil, (owing to paresis of the ciliary nerves from direct pressure on them).

Patients then, labouring under this form of the disease, will come to you complaining merely of failing vision, you investigate the intra-ocular tension and find it more

or less above the normal tension. You then examine the fundus oculi with the ophthalmoscope (a proceeding unattended with difficulty in this form of the disease, as the ocular media remain clear), and you find the remarkable appearance shown in these drawings.\* The surface of the disc, or optic entrance, instead of corresponding almost exactly with the surface of the retina, as it does in the normal eye, is pushed back, so that the appearance of the excavated or cupped disc is presented. The surface of the disc is often driven further back than the external surface of the sclerotic itself. This cupping of the disc results from the fact, that it is the least resisting point of the coats of the eyeball, inasmuch as here the sclerotic is perforated (cribriform plate) by the filaments of the optic nerve as they enter the eye. In accordance with hydrostatic laws, the pressure within the eyeball must be equal on every part of its walls, and of course the weakest point of these will be the first to give way to an abnormally high pressure. In commencing glaucoma, we may find no cupping of the disc, as it requires the tension to have reached a certain height, and to have lasted a certain time before this effect of it is produced. The high pressure upon the disc and retina paralyses these tissues, and so produces disturbance of vision. The defects of sight display themselves in central vision, so that the patient cannot read so well, or distinguish small objects with his former precision; but, what is of much greater importance for the diagnosis, and in the long run for the patient too, are defects in the eccentric portions of the field of vision, which are apt to be present. They should be looked for, *by lamplight*, in the following way:—directing the patient to close one eye, you cause him to steadily fix the other one (to be examined) on some object at about two feet removed from it (*e.g.*, your hand, or face); you then move a whitish object (your hand) slowly round in the periphery of his field of vision, and about one foot removed from its centre, and observe whether there be any position where the motion of the object can not be seen. If the glaucoma be somewhat advanced, you will almost constantly find a defect in the inner and upper region. At a still later period this defect may extend all round the periphery of the field of vision, and encroach also towards its centre, so that then the patient finds himself in a condition, which any of you may realise to yourselves, by closing one eye and looking with the other through a roll of music or other small bored cylinder. At last this little remaining glimpse of the world is swallowed up by the ever advancing enemy, and the patient is left in irremediable darkness. Or, the defect in the field may merely advance towards the central point (point of fixation, macula lutea), and having attacked it go no further; such a patient would only be able to see objects held to one side of his field of vision.

Inflammatory glaucoma, of which you have here an example, has a very different course. It rarely extends over a term of more than a year, and usually but a few months. The tension is not a steadily increasing one, but advances in fits and starts, called "attacks of glaucoma." Each attack is attended by dimness of vision (often described by the patient as smoke in the room), by the appearance of rainbows round the candle or lamp, by severe ciliary neuralgia, which extends down the side of the nose, into the malar bone, and into the corresponding brow and side of the head, there is also much tearing and sensitiveness to light, and frequently vomiting. If then, you examine the eye during an attack of this nature you will find it very hard, the anterior chamber shallow, a bright injection surrounding the cornea, and much engorgement of the episclerotic veins. In consequence of pressure upon the ciliary nerves, the sensation of the cornea becomes greatly diminished, as you may discover by touching it with a small shred of paper. You may observe that in the case before us to-day, there is complete anaesthesia of the cornea. In these attacks of glaucoma, you will often find the aqueous and vitreous

\* Liebreich's "Atlas of Ophthalmoscopy." Translated by H. R. Swanzy. London, 1870. Plate xi., figs. 8 and 9.

humours so opaque, that, even if the photophobia allow of the examination, the fundus oculi can scarcely be seen with the ophthalmoscope, the optic disc, appearing but indistinctly, somewhat like the sun when seen through a thick fog. Such attacks vary of course in their intensity, from something which the patient himself hardly observes, to one like that I have described. An attack of glaucoma frequently lasts several hours. When it has subsided the media become clear again, the vision becomes almost as distinct as before, and the tension returns nearly to its former condition. Every attack, however, adds something to the permanent intra-ocular tension, takes something from the acuteness of vision, makes another advance towards cupping of the disc, and towards atrophy of the nervous tissues. As the disease gains a footing, the attacks become more frequent. Instead of returning once a fortnight they come once a week, then perhaps once every second day, or every day. At last an attack comes which has no complete intermission, although it may diminish in severity for a few hours, and when this happens we say that the glaucoma itself has arrived. The last moment for the exercise of your art will then also have arrived, for a few days would otherwise suffice to extinguish vision. If the disease be still let run its own course, although sight be completely lost, yet the most violent ciliary neuralgia may continue for months. The eye is gradually disorganised. Cataract forms, and the iris becomes atrophied. Such is the condition of our patient's eye. Still later, the glaucomatous process leads to ectasy of the sclerotic, purulent inflammation may then come on, and end in phthisis of the eyeball.

Glaucoma, of both forms, is most commonly double sided. Both eyes may be attacked about the same time, but more usually there is an interval of weeks or months, or even longer. In this man the second eye still continues healthy.

Until within the last fifteen years a successful treatment for this terrible disease was unknown. Patients suffering from it, and applying to a surgeon for aid, were simply allowed to go home and get blind. It is to Von Graefe that humanity is indebted for the great discovery that abscision of a portion of the Iris (Iridectomy) would relieve increased intra-ocular tension. In 1857 he published his first great monograph on the subject; and thousands are the eyes which have been saved since then by the operation. Graefe arrived at this discovery by a remarkable process of clinical observation, of which it would be difficult to convey to you an adequate idea. We are still ignorant as to how iridectomy has the effect of reducing increased intra-ocular tension. Doubtless, one day, this too will be discovered, and I think most likely then, when the cause of the increased pressure itself becomes known. In the meantime, we may be well contented to practise the treatment without being acquainted with its mode of action. How many medicines are administered internally quite as empirically?

In order to perform the iridectomy with a successful result, it is important you should attend to two points. 1. The portion of iris must be excised to its very periphery. 2. It must be a sufficiently wide piece. The first point is attained by making your incision into the anterior chamber, with the little iridectomy knife, as far back as possible, *i.e.*, in the corneo-sclerotic border. The width of the portion of iris excised will depend upon the length of the wound, because, on withdrawing the knife, the aqueous humour flows out and carries with it a section of iris corresponding to the extent of the wound. This, then, is seized with a fine forceps, gently drawn forward a little, and snipped off with the scissors close to its base.

The earlier in the disease iridectomy is performed the more perfect is the result obtained, for, in general, we may expect by the operation to retain the degree of vision which exists at the time, but we can rarely calculate upon restoring what is lost. Eccentric defects of the field of vision do not recover after the operation; at best, central

vision may improve somewhat. You will find the results of the iridectomy in cases of inflammatory glaucoma almost uniformly satisfactory. In cases of simple glaucoma, on the other hand, the operation sometimes appears to arrest the disease only temporarily, and you may afterwards have to employ a second iridectomy in order to complete the cure, and there are sometimes cases in which even that does not produce the desired effect, and where in spite of all your exertions the eyesight will be lost.

Glaucoma is a disease of old age, seldom making its appearance in persons under forty-five.

Before I conclude, I must mention another form of glaucoma, which fortunately is very rare, but for which you should be prepared, namely, glaucoma fulminans. It resembles inflammatory glaucoma, except that it has no premonitory stage, it gives no notice of its approach, but suddenly attacks an eye, which has apparently been until then, perfectly healthy. It comes on with great violence, and frequently destroys vision in a few hours. It consequently admits of no delay in the performance of the iridectomy.

I shall now proceed to operate on the case before you, not with any expectation of restoring a spark of vision to the eye, for the time for this is long since past; but in the hope of relieving the frightful neuralgia from which the patient is, and has been suffering for some months. Even in this I may not succeed; for, when the iris has become so atrophied as you see it here, we cannot speak of the result of the iridectomy with as great certainty as we otherwise could do. In case the pain be not allayed by the operation, I shall be obliged to resort to enucleation of the eye-ball.

## Original Communications.

### POISONING OF PIGS WITH COMMON SALT.

By CHARLES A. CAMERON, PH.D., M.D.,

Professor of Hygiene, Royal College of Surgeons; Analyst to the City of Dublin.

THE following case of "pigs poisoned with common salt" is, I think, not devoid of interest:—On the night of 7th October, 1871, a train arrived at the terminus of the Liffey branch of the Midland Great Western Railway. In it was a consignment of sixty-two pigs, contained in two waggons. In one of the waggons thirty-one of the pigs arrived perfectly safe and in good condition; but the next waggon the pigs (31 in number) were found, without an exception, in so very sickly a condition that the consignee would not receive them. The fact of diseased pigs being at the railway station was communicated to the Municipal sanitary authorities, and I inspected the animals early on the 8th October. Before my arrival four of the pigs had died, and sixteen had been killed whilst apparently dying. Eleven were still alive, but they appeared to be not far from death. On examining the carcasses of several of the pigs, I could not perceive any symptoms of the ordinary diseases which affect those animals, and it at once occurred to me that they had been poisoned. On closely examining the waggon in which they had been conveyed, I found nothing of a poisonous nature; but quite casually I happened to observe a few grains of a white powder on one of the hinges of the door, and this on examination proved to be common salt. The idea at once occurred to me that the pigs had been poisoned with common salt; and subsequent inquiry elicited the fact that the animals had been conveyed in a waggon which had previously been laden with salt. It would appear that the pigs had been for many hours without any liquid, and that they licked up the salt when on the floor of the waggon. The surviving pigs I ordered to be given emetics, and subsequently stimulants, and they all revived under that treatment.

On making an examination of the carcasses, I found

general, but by no means severe, signs of gastro-intestinal inflammation. A teaspoonful of the semi-liquid contents of the stomach of one pig contained about three grains of common salt; but there was not much food in the stomach. The brain was greatly congested, and there was considerable extravasation of blood in the cerebellum and medulla oblongata.

I have not the slightest doubt but that the death of these pigs was the result of the action of common salt upon their economy. The chemical analysis of their viscera proved the absence of ordinary poisons, and the animals had certainly not died from any of the usual diseases to which pigs are liable. I am quite satisfied, then, that salt was the cause of death; but I am not so certain as to the *modus operandi* of the poison. The inflammation of the digestive canal was hardly sufficient to cause death; and it seems strange that the chief effect of the poison should be observed in the brain. If the salt had acted as a simple irritant poison we might naturally expect to find the evidence of its action more palpable in the digestive organs than in the brain. As the animals, no doubt, had been thirsty, and their mouths parched, might it not have happened that the salt which they had licked induced a spasm of the glottis, and brought on apnoea? When I first saw the pigs my impression was that they were in a state of asphyxia, and I inquired whether or not they had been conveyed in a close waggon. I found, however, that the pigs had not been overcrowded, and that the waggon was almost without a roof. I should observe that I found a little salt in the nostrils of one of the pigs.

This is not the first case of poisoning with common salt. Dr. Taylor mentions cases of human beings who lost their lives from the use of an excessive quantity of salt. About five years ago, a case where eight pigs were poisoned by getting too much salt on their food came under my own observation. In the *Veterinarian* for 1855 a case of "poisoning of pigs with common salt" is reported by Mr. Robinson, of Tamworth; and in the *Veterinarian* for December, 1862, Mr. H. Pyatt, M.R.C.V.S., of Nottingham, describes another case of the kind. He states that several pigs which were receiving about four-and-a-half ounces of salt per day in their food died, and that he "felt perfectly satisfied that all the mischief has arisen from the quantity of salt the pigs were eating." On discontinuing the use of the salt, the pigs that had not died, but were sickly, soon recovered.

I often hear of pigs dying suddenly without exhibiting the symptoms of the ordinary maladies. Occasionally the viscera of such animals are submitted to me for analysis, but the presence of ordinary poisons in them is the exception, and not the rule. In future, when such cases come under my notice, I certainly shall determine the amount of salt present in the stomach; for it may be that death from over quantities of salt results far more frequently than we have hitherto been led to believe was the case.

### COMPLICATED CASE OF DISEASE OF THE LUNG AND KIDNEY.

By DUNCAN R. McNAB, M.R.C.S.E., and TREVOR FOWLER, L.K.Q.C.P., L.R.C.S., &c.

DURING last month (September, 1871) we were consulted by Nathaniel Smith, a publican and greengrocer, aged forty-seven, who had previously led an intemperate life, and was now complaining of great debility, cough, and dyspnoea, loss of appetite, frequent sickness, flatulence, and indigestion, troublesome hicough, slight pain in the epigastrium and right side towards the back, and sleepless nights. He was thin, pallid, cold, and feeble, had a weak action of heart, quick and feeble pulse, accelerated respiration, dulness over the left lung, and rough breathing in same, red and somewhat dry tongue, appa-

rently healthy evacuations and urine, assumed light-heartedness, but too evident anxiety and irritability.

These symptoms were soon followed by lividity of the face and extremities, expectoration of blood and pus, and extreme dyspnoea, a blue tongue, dry and brown upon its surface, persistent hicough, increased anxiety, and restlessness and death.

Upon making a post-mortem examination we found the left lung adherent to the anterior wall of the thorax, very much diseased and broken down. The right lung was healthy. The aortic valves of the heart were red and rough, apparently the result of inflammation. The liver was enlarged, and its surface studded over with dark star-shaped spots about the size of leech-bites. The gall bladder contained a fair quantity of healthy bile. The spleen, stomach, and bowels were healthy. The left kidney was not larger than a walnut, but of healthy structure; the right was as large as a cocoa-nut, and upon its surface were the appearances of inflammation; in its substance were several small abscesses, and in its upper portion was a large irregular cavity lined by a thick pyogenic membrane, and opening into the pelvis of the organ.

Epping, Essex.

### ON THE USE OF THE INFUSION OF TOBACCO LEAVES IN VAGINITIS.

By LOMBE ATHILL, M.D.

IN the number of the *MEDICAL PRESS AND CIRCULAR* for the 21st June last, I directed attention to the benefit which frequently results from syringing the vagina with the infusion of tobacco leaves, and I stated "that I had never seen the least unpleasant results follow its use."

Since then, however, I have met with two instances in which faintness and nausea occurred as results of this treatment.

In one the patient was a young recently married girl, in whom the orifice of the vagina was exceedingly small, and marriage had consequently not been consummated; but the repeated attempts at intercourse had brought on an acute attack of vaginitis. With view of alleviating her sufferings, I directed this patient to use the infusion of tobacco as a vaginal lotion in the usual manner, by means of a syphon syringe. However, she became faint, and complained of nausea after having injected a very small quantity of the fluid. These symptoms passed off in a few minutes. The other instance occurred in the case of an unmarried girl of weakly leucophlegmatic temperament, in her case, too, the vaginal orifice was very small. The symptoms she exhibited were not so well marked as in the former case, still, they were of sufficient importance to compel me to give up the use of the remedy. I am of opinion that, in both of these cases the extreme narrowness of the orifice of the vagina permitted some of the fluid to be retained in the vagina, and that it was consequently absorbed. I am also inclined to think that both patients were peculiarly susceptible of the action of the drug. However, I shall, for the future, cease to direct the infusion of tobacco to be injected into the vagina in cases in which the orifice of that canal is not sufficiently patulous to allow of the free escape of the fluid. I find that the addition of two or three drachms of borax to the infusion, greatly enhances the value of the remedy. And I now invariably order it to be added to the infusion of the leaves.

## Hospital Reports.

METROPOLITAN FREE HOSPITAL.

(Under the care of Dr. C. R. DRYSDALE.)

MOSES HENRY is thirty-nine years of age; married for

two years; occupation a tailor; been in very good health all his life.

*Present attack* came on last Christmas, with a cold in his head as he says, hemicrania (right side). There were ringing noises in his head; he could not hear well; there was a good deal of tenderness about the mastoid process; his right ear was filled with wax, which he syringed out, and there has been a whitish yellow discharge from his ear ever since, and in a good quantity sometimes mixed with blood; his hearing was not improved by the wax coming away.

Oct. 8th.—There is tenderness over the mastoid process; right hemicrania; feels giddy; cannot hear well; noises like a steam engine in day; when he coughs, says there is air comes through the external meatus; there is a large quantity of purulent discharge from the ear daily; left ear is all right; tongue dirty brown; pulse 104; bowels confined; has a slight attack of bronchitis.

Ordered *Ol. ricini.*, ℥j.;  
*Ammonia carb.*, gr. v.;  
*Vin. ipecac.* m. x.;  
*Dec. cinchona*, ℥j. t.d.s.

Ears to be syringed out three times a day with warm water, and then with the following injection:—

*Tinct. sulph.*, gr. ½;  
*Aqua*, ℥i.

Oct. 13.—There is still a good deal of headache; two small pieces of spongy bone have come away since last report; tongue furred; pulse 100; there is a good deal of discharge from the ear, mixed with blood; there is a dusky redness of the throat.

℞ *Potass. iodide*, gr. x.;  
*Aqua*, ℥j. t.d.s.

Oct. 20th.—Headache not so severe; tenderness over mastoid process increased by opening mouth; the discharge has greatly diminished in quantity; feels a good deal better; back of ear painted daily with iodine.

Oct. 24th.—Two more small pieces of bone came away on the 21st; there is scarcely any discharge from the ear; headache very slight; is in better spirits, and has decidedly improved since admission.

*EMILY MERCER.—Family History.*—Father died at forty-one, of consumption; was subject to sore throat; never noticed any rash on him; mother living, aged forty-two; has had twelve children, of which only three are living, the second, the eleventh and twelfth, the others all died before three years of age, of a kind of wasting; noticed a rash on most of them, but no snuffles; the first child died when four weeks old, but never noticed any sores on its privates; the eleventh and twelfth children are in good health; mother has been married seventeen years, when first married she had some sores on her privates given to her by her husband, she says they were followed by a rash upon her arms, and sore throat, the latter she has had occasionally ever since, attended with ulcers in her mouth and soreness of the roof; used to have lumps on her head, but there are none now; no loss of hair.

*Patient's history.*—She is sixteen years of age; never menstruated; she is the second child; when an infant, her privates were very red and sore; no snuffles or rash on her body, but was very emaciated; she has had bad sight since seven months old; there is now the remains of an ulcer on her left cornea over the pupil, can see best with her right eye; she had an old look about her; when a year old her chin broke out in sores; has had small ulcers in her mouth off and on since a child. When three years of age, a lump formed on her ankle; matter formed, it burst, and the scars can be seen now.

Her first set of teeth were very bad, being black and soon decaying; never noticed any lumps on her head or on her bones; complexion always been muddy.

Has had about three fits a week for five years, generally in them five minutes; her arms and legs are convulsed; she turns livid, but no foaming at mouth, or biting of tongue, says she can see and hear what is going on whilst

in them; they come on with a queer sensation in the throat, so that she cannot speak; she generally knows when she is going to have one; often troubled with headache; scarcely ever sick; pupils normal. There are a number of striæ running from the lower lip and angle of the mouth, over the chin.

About a year ago, she fell on going up stairs, and an ulcer formed on the inner side of her left arm, a little above the elbow, it commenced as a red spot, about the size of a pea, but gradually got larger till it measured five inches long, and three and a-half inches in width, with very irregular edges; she has had medical advice, but none to do her good, till admitted here.

℞ *Potass. iodidi*, gr. 1½;  
*Vin. ferri*, ℥ij.;  
*Tinct. tingiber.*, ℥iij.;  
*Aqua*, ℥. t.d.s.

Full diet, port, ℥vj., per diem. Arm to be dressed with black wash.

Nov. 3rd.—The patient has greatly improved under the above treatment; the ulcer upon the arm is nearly healed; it has been dressed the last two weeks with carbolic acid lotion; she has the fits much the same as when she came in, but, in other respects, her general health has greatly improved.

## CLINICAL RECORDS FROM PRIVATE AND HOSPITAL PRACTICE.

### I.—OXYGEN IN DISEASES OF THE LUNGS.

By HENRY N. READ, M.D., House-Surgeon, Long Island College Hospital.\*

(Continued.)

*CASE V.*—George Graham, æt. forty-three; Scotland; sailor; admitted December 2, 1870. Has had cough and expectoration, beginning six weeks ago; has anorexia, hectic, night-sweats, and has lost much flesh, is quite weak. Gives family history of tuberculosis. Right lung dull at apex, dullness extending down to third rib; bronchial breathing, subcrepitant rales, &c. Pulse, 98; temperature 99½°; weight, 146 pounds. Ord. three gals. gas, and ol. morr., daily.

December 23rd.—Patient has improved in many respects, has gained ten pounds in weight; pulse and temperature normal; has an excellent appetite, and but slight cough.

January 12th, 1871.—Continues to improve; has gained four pounds since last record; had slight hæmoptysis last week; no night sweats, and but little cough. Is anxious to be discharged.

February 1st.—Patient discharged to-day, and went back to his ship. Weight 164 pounds—a gain of 18 pounds since admission. The diseased lung has resumed its function, and little or no deposit remaining can now be recognised.

*CASE VI.*—Jane Davis, æt. forty-eight; England; seamstress; admitted January 7, 1871. Was attacked with pneumonia about six weeks since; was confined to bed for three weeks. She has continued to cough ever since, and spits large quantities of dirty, offensive matter. Has exhaustive night-sweats, no appetite, stomach irritable, and is very weak. Base of right lung dull over a considerable extent, with subcrepitant rales heard over lower lobe. Has been a healthy woman all her life, and has, so far as can be learned, no hereditary taint. Was ord. two gals. gas daily, with quin. sulph. grs. ij, acid. sulph. arom. gtt. xx. *ter die*; nutritious diet.

January 13th.—Began to improve soon after taking the gas. Eats heartily, expectorates freely, and the lung is evidently clearing up. No night sweats, and nausea has disappeared.

\* From the *New York Medical Journal*.—We regret that this footnote acknowledging the source of these cases, was accidentally omitted in our last issue.—Ed. M. P. & C.

January 26th.—Discharged to-day entirely well. Sounds in lung, normal. Strength and appetite as good as usual.

CASE VII.—Martin McCarthy, æt. thirty-two; Ireland; tailor. Admitted January 2nd, 1871. Has lost several of his family from consumption. Has enjoyed good health, with the exception of syphilis, which he contracted three years ago. Four months since he commenced to cough and expectorate yellow sputa; this has continued to the present time, and he has had two free hæmorrhages. He is quite thin of flesh and weak; has hectic and is very anæmic. Tongue slightly coated, bowels constipated, stomach irritable. Weight 106 pounds. Pulse 102; temperature 100° to 100½°; apex of right lung dull as far as third rib, with bronchial breathing and bronchophony, but few *râles*. Ordered two gallons of gas, morning and evening, ol. morrh. Bowels to be regulated *pro re nata*.

January 26th.—Has gained four pounds in weight, night sweats have left him, but he continues to expectorate freely; appetite good; complains of slight rheumatic pains.

February 6th.—A severe attack of tertiary syphilis has manifested itself; violent osteopic pains, and nodes have appeared on tibiæ and sternum. Ol. morrh. stopped. Ordered potas. iodid. G. j. *ter die*, and the following R: syr. ferri hypophosp., syr. calcis hypophosph., syr. potas. hypophosp., ãâ, ℥j. M. S. ℥j. after-meals. Gas continued with nutritious food.

February 18th.—Specific trouble been apparently arrested. Potas. iodid. stopped. Continued syr. of hypophosphites. Much better; weight, 115½ pounds; dulness of lung, much less extended; voice-sounds and respiration, much less intensified. Ol. morrh. resumed, gas continued.

March 1st.—Discharged to-day; weight 120 pounds. Returned to his work. Examination of the lung shows it nearly normal.

CASE VIII.—Michael Dougherty, æt. fifty; Ireland; stone-mason. Admitted January 7, 1871. His father died from consumption. Has been a healthy man till last summer, when he had an attack of sunstroke; on recovering, a cough set in, with hæmorrhage from the lungs. Has continued to cough and lose flesh; is very weak; has anorexia, hectic, etc. Examination shows a large cavity in apex of right lung, gurgling *râles* heard, lung solidified to a considerable extent. Ordered four gallons gas daily, ol. morrh., and good diet. Pulse 118; temperature 102°. Weight 129 pounds.

February 6th.—But little change except in pulse and temperature, both of which have been reduced, former to 100 to 105, latter 100° to 100½°.

February 17th.—Has improved somewhat, better appetite; pulse and temperature nearly normal. Physical signs show the cavity empty, and but few mucous *râles*. He has, however, lost one pound in weight and coughs freely; no night-sweats.

February 25th.—Patient left hospital to-day, and returned home. Has lost two pounds in weight since admission; weight 127 pounds. With this exception he has improved; has a good appetite and no hectic. The cavity in lung is empty, and the lung is clearer than formerly, though much deposit is still present, and he coughs considerably.

CASE IX.—John Sundin, æt. twenty-one; Sweden; sailor. Admitted January 16, 1871. Inherits the *tuberculous diathesis*. Had had cough, more or less, for three years, but it has only excited alarm within this last three months. He has been rapidly reduced within this time, has diarrhoea, night-sweats, etc. Temperature 101°; pulse 106; weight 130 pounds. Cavity in right lung nearly filled with fluid; the whole substance of this lung appears diseased, and a slight tuberculous deposit is detected in apex of left lung. Ordered four gallons gas daily, with ol. morrh., and the usual diet.

January 25th.—Slight improvement. Temperature averages 98½°.

February 6th.—Is discovered to have stricture of the

urethra, with trouble in passing water; diarrhoea checked; gained two pounds in weight since last record; appetite good.

February 25th.—Physical signs show right lung to be improving, cavernous breathing not so marked, but the deposit is apparently in left lung; cough also very bad, and has copious night-sweats. Ordered two additional gallons gas daily; *mist. tussis* of Case II.; quinia and acid. The passage of the bougie disturbs him so that it is discontinued; stricture admits of a No. 7 instrument. Weight 134 pounds.

March 18th.—Patient left hospital to-day to return home. Right lung continued to improve, but the left became seriously implicated, and he expectorates profusely. Weight 134 pounds—a gain of four pounds; but he is weak and unable to work, and, on the whole, the treatment has not been satisfactory in this case.

It will be seen that the results in Cases VIII. and IX. were unfavourable. Though the general health of both patients was much improved, and their lives in all probability prolonged, yet the disease was not arrested, nor was the prognosis, at the time of their departure, favourable. The advanced state of the disease in these cases was an unfavourable element, as was the age in Case VIII., and the existence of urethral stricture in IX.

CASE X.—James Davis, æt. thirty-three, United States; sailor. Admitted January 14, 1871. Attacked with pneumonia three weeks ago while at sea, and was confined to bed. The inflammation involves the lower and middle lobes of right lung, and is now evidently undergoing resolution; subcrepitant *râles* heard; percussion dull; continues to spit rusty sputa; is quite weak, and sweats profusely. Family history clear from all taint, and he has been a strong, healthy man all his life. Weight 147 pounds. Ordered two gallons gas, daily; quin. sulph. grs. ij., four times, daily, with generous diet.

February 16th.—Inflammation manifests a tendency to become *chronic*; still sweats considerably; has sharp pains through side, and has gained no flesh, though appetite is better. Ordered two additional gallons gas, daily; quinia continued; counter-irritation over diseased lung.

March 10th.—Patient improving. Weight 161 pounds. Sweats have disappeared, and he coughs very little. Lung clearing up; only a slight dulness, with exaggerated respiratory murmur at base.

March 21st.—Discharged to-day. Weight 168 pounds. Shipped again. Examination shows right lung entirely clear.

CASE XI.—Martin Spelman, æt. twenty-six; Ireland; labourer. Admitted January 17, 1871. Was attacked ten days ago with pneumonia, partial, of both lungs; has cough, rusty sputa, pain in side, etc. Is very weak; pulse 136, and very laboured respiration; temperature 104°. Dulness on percussion at the bases of both lungs, with crepitant and subcrepitant *râles* heard above.—Ordered two gallons gas morning and evening, quinia and supporting treatment.

January 19th.—Much better; the gas has relieved the difficult breathing very much. Pulse 106; temperature 101°.

February 10th.—Patient improved rapidly since last note; lungs quite clear, except slightly-exaggerated respiration at the base, with subcrepitant *râles*. The weight was not obtained, as the patient was too sick on admission to be taken out; he is, however, in excellent condition and appearance. Discharged to-day.

CASE XII.—Michael Wallace, æt. twenty-six; Ireland; labourer. Admitted January 18, 1871. No history of hereditary tuberculosis. Was taken with cough and expectoration about a year ago, after considerable exposure. Had a hæmorrhage last May, none since. Has lost much flesh; anorexia, night-sweats, etc. Temperature 102½°; pulse 102. Right lung dull at apex; dulness extending to middle lobe behind, but not so far in

front; the usual voice and respiratory sounds found. Weight 136 pounds. Ordered three gallons gas, daily, with ol. morrh. and good diet.

January 30th.—Improving; temperature, 99° to 100½. Cough still troublesome; expectorates freely. Has a good appetite, and has gained four pounds in weight. Ordered the *mist. tussis* of Case II., and one gallon more of gas, daily, making four gallons in all.

February 15th.—Improving rapidly; weight 143 pounds; temperature 99°. Cough much better, and lung clearing up; dulness only found at apex. Treatment continued.

February 25th.—Discharged to-day. Says he "feels as well as ever." Lung quite clear. Weight 156 pounds—a gain of twenty pounds since admission.

## Foreign Medical Literature.

### THE RELATIONS BETWEEN HÆMOPTYSIS AND PULMONARY TUBERCULOSIS.

A CLINICAL LECTURE BY PROF. SKODA.

(Translated from the *Annales et Bulletin de la Société de Med. de Gand* for the *Boston Med. and Surg. Journal*.)

PROF. NIEMEYER has recently assigned to hæmoptysis an importance entirely unlike that which it formerly was held to possess. He believes that tuberculosis is caused by the hæmoptysis itself, maintaining that the blood arrested in the bronchial tubes and in the air-cells after a hæmorrhage gives rise to a chronic inflammation, and that on this depend the febrile state and the other symptoms of phthisis. If the blood thus retained in the minute bronchi and in the air-cells really possessed such an influence and could excite such an inflammatory state, we ought to expect that the same result would follow hæmorrhages which attend cardiac disease. Now no such condition occurs in the course of that affection. Where an hæmoptysis takes place in patients whom we consider to be tuberculous and who die during the hæmorrhage or soon after, we do not generally find any arrest of accumulated blood in the bronchi and air-cells; while if death occurs after a hæmorrhage in diseased heart, there is found a collection of blood in the lung. The hæmorrhagic infarctus very rarely presents itself after the hæmoptysis of tuberculosis, and is an exceptional occurrence in cardiac disease. But it is this very thing which would determine the conditions of a chronic inflammation! I have never seen such a result. Doubtless, it accumulated blood does remain, a moderate reaction occurs, in the course of which only the normal changes of the blood take place; that is, it coagulates, becomes encysted and forms the infarctus alluded to, but never progresses to suppuration. Such a hæmorrhagic infarctus may last months and years, growing smaller and smaller, and finally disappearing altogether. The blood-globules undergo a metamorphosis by which the black pigment is the result, or else disappear by fatty degeneration. The fluid elements, which become separated from the rest, are reabsorbed; the dark-colouring matter is left, and if the hæmorrhagic infarctus continues any length of time it remains as black patches in the substance of the lungs. According to this view, then, the observations relative to the effusion of blood in the lungs in the course of disease of the heart accord so little with the theory of Professor Niemeyer, that one is forced to confess that this hypothesis is untenable.

According to the investigations which have been made in the living subject and upon the cadaver, it is very probable that the hæmoptysis which occurs in pulmonary tuberculosis before and during its development, has its seat in the mucous membrane of the bronchi, and not in the air-cells. If the blood came from the latter, it would certainly be very difficult to explain the rare occurrence of the hæmorrhagic infarctus; but since it comes from the bronchial mucous lining, it is easy to see that none

remains as a plug, but that it is expelled by coughing. I can state positively that in cases in which death occurs in the course of an hæmoptysis, it is the rare exception to find blood in the bronchial tubes, but that it is found rather in the larynx and the trachea; because, by the cough and the contraction of the bronchi, it is at once drawn forward and expelled.

So, too, I cannot accept the theory that the hæmoptysis may give rise to serious after-effects. Such a result can be only in cases in which the hæmorrhage occurs in a lung tissue already diseased, especially in cavities from which the blood cannot be evacuated; and it is possible that the morbid properties peculiar to the cavities themselves contribute thus to develop a more active irritation. It is, moreover, to be noted that the blood is not specially irritant to the tissues; for example, a hæmorrhage into the subcutaneous tissues after a blow does not produce any marked irritation, as we very well know, but it is generally quickly reabsorbed; so there is no reason for supposing that the blood is so irritant in a tuberculous patient as to favour the farther development of the symptoms of the disease. Nevertheless, I attribute a great importance to hæmoptysis, but only as a symptom indicating that the disease is present, or that it is in process of development.

Another question here presents itself. When directly consequent upon an acute pneumonia, there remains some of the inflammatory product in the lungs, a chronic pneumonia is said to exist. This deposit differs materially from those peculiar to the disease which we call tuberculosis. The former can remain months and years without lighting up mischief, while in tuberculous disease cavities become formed with the greatest ease. I see, therefore, an important distinction between the two diseases, and it is useless to apply terms in common which may give rise to confusion.

Therefore we see that hæmoptysis is not the cause of consecutive disease of the lung; on the contrary, the cause of the pulmonary disease resides elsewhere, and the hæmorrhage is only a symptom of a morbid predisposition which subsequently manifests itself under the form of tuberculosis.

Hæmoptysis likewise proceeds without doubt from other causes, cardiac disease for example. Moreover, certain cases of hæmoptysis occur independent of disease of the heart, having no connection, indeed, with eventual pulmonary disease, cases in which the hæmorrhage frequently recurs but with no serious pulmonary affection consequent. But such instances are rare, and are sometimes dependent on a tuberculous degeneration limited to a single point in the lung; which, once diseased, never returns perfectly to its normal state, and becomes the seat of hæmorrhages which recur from time to time. Other cases also are observed in which the extravasation of blood proceeds solely from the capillaries or from dilated veins, among which aneurisms by anastomosis are found. Doubtless a metamorphosis of the pulmonary parenchyma can thus give rise to a serious attack of hæmoptysis; these attacks may recur, and yet no tuberculosis ever result; when the hæmorrhage ceases, the patient regains his previous health; debility may result, as in other cases of hæmorrhage, but farther than this there exists no other symptom worth noting.

## THE SEWAGE QUESTION.

### SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XXX.

### AGRICULTURAL VALUE OF SEWAGE.

THE experiments at Rugby with milch cows were rather more satisfactory, as will be seen from the following account of them. "In 1861, twelve of Mr. Campbell's cows

were carefully selected and set apart to be fed on grass alone—two on unsewaged, and ten on sewaged grass, and the experiment was so conducted over a period of sixteen weeks. It was afterwards continued for four weeks longer with an allowance of oil-cake as well as grass. In 1862, three cows were selected to receive oil-cake and unsewaged grass, and twelve oil-cake and sewaged grass, and the experiment was continued for twenty-four weeks. In 1863, twenty recently-calved cows were selected, five to be fed on unsewaged meadow grass, ten on sewaged meadow grass, and five on Italian rye grass. The design was to give each lot grass alone for the first twelve weeks, and afterwards a certain amount of oil-cake in addition."

The results of these experiments are shown in the following table:—

RESULTS OF EXPERIMENTS ON MILCH COWS WITH UNSEWAGED AND SEWAGED MEADOW GRASS ALONE, AND WITH OIL-CAKE.

|  | 1861.            |                | 1862.      |      |          |      | 1863.      |      |          |       |

"Reviewing the results of the experiments in which sewaged was tried against unsewaged meadow grass, it is observable that, excepting in the first season (1861), the cows required more, both per head per day, and per 1,000 pounds live weight per week, of the fresh or green sewaged than of the unsewaged grass; yet the yield of milk, both per head and per 1,000 pounds live weight, was, without exception, the greater with the unsewaged grass. The increase in live weight was also somewhat the greater on the unsewaged grass in 1861 and 1862, but the contrary was the case in 1863."

"Reckoned in the fresh or green state in which it was cut and carted, there was, in fact, in every case but one (and then the quantities were equal), considerably less of the unsewaged than of the sewaged grass required to be consumed for the production of one gallon of milk. It should be remarked, however, that the unsewaged grass was generally cut in a much riper and less succulent condition, and therefore contained a considerably higher percentage of dry or solid substance than the sewaged. It may also be here mentioned that in 1863 the cows having professedly unsewaged meadow grass, in default of a sufficient supply of it, had necessarily for a considerable part of each of the periods of twelve weeks, unsewaged rye-grass."

"Weight for weight, in the fresh or green state in which the grass was cut, weighed and given to the cows, the unsewaged grass has, therefore, proved to be far more productive than the sewaged. But when the comparison is made, not between the amounts of grass reckoned in the fresh state, but between the amounts of dry or solid matter which the different descriptions of grass supplied, the result is, that in only one instance was there more, and in the others there was either an equal amount or even less of dry or solid substance of sewaged than of unsewaged grass required for the production of a given amount of milk."

The general result, therefore, in regard to these points was that in both milk and increase, but especially milk, a given weight of animal was more productive when fed on unsewaged than on sewaged grass, and that a given weight of fresh unsewaged grass was more productive than an equal weight of fresh sewaged grass; but that a given weight of dry or solid substance supplied in sewaged grass was more productive than an equal weight supplied in unsewaged.

As regards Italian rye-grass the experiments were not conclusive, as the sewaged and unsewaged grass were given indiscriminately to the cows. It seems, however, that when grass alone was made use of, the animals consumed 159.3 lbs. per head per day. These contained 31.7 lbs. of dry solid matter, and yielded 31.4 lbs. of milk—so that 52.3 lbs. of grass, containing 10.4 lbs. of dry solid matter were required for a gallon of milk. When the rye-grass was supplemented with 3.3 lbs. of oil-cake daily, the average daily consumption was only 121.3 lbs., and the yield of milk was 28.1 lbs. per diem. On this head the Commissioners say that, "the experiments do not afford the means of strictly comparing the productive qualities of rye-grass with those of meadow grass, or of sewaged with those of unsewaged rye-grass," although the "indication is that somewhat more of the dry substance of the sewaged rye-grass than of the sewaged meadow-grass was required to produce a given result, though the difference is less during the later than the earlier period of the season. It is pro-

bable, indeed, that sewaged Italian rye-grass deteriorates less towards the end of the season than the sewaged meadow grass;" for it was noticeable that the milk-producing power of meadow grass was very different in different seasons, and at different periods of the same season. It was, in fact, very inferior in the wet and cold season of 1862, and towards the close of every season as compared with the beginning. But on an average of the three years about six parts of green grass yielded one part of milk, and as the production of grass was greater on the sewaged than on the unsewaged land, the total yield of milk per acre was much greater in the former case than in the latter.

"So far as the results of the experiments afford a means of judging, it is estimated that with an application of about 5,000 tons of sewage per acre per annum to meadow land, an average gross produce of not less than 1,000 gallons of milk per acre per annum may be expected;" and this at 8d. per gallon would give a return of from £30 to £35 an acre.

The quality of the milk in the two cases was carefully tested, and it was not found to differ to any great extent, although it was slightly less rich in the case of the milk from the sewaged grass than in that from the unsewaged. This will be apparent from the following table, which represents the average composition of forty samples of milk taken during the years 1861 and 1862:—

THE MEAN COMPOSITION OF THE MILK PRODUCED FROM UNSEWAGED AND SEWAGED GRASS.

| Constituents of Milk.  | Season 1861. |          | Season 1862.        |          |
|------------------------|--------------|----------|---------------------|----------|
|                        | Grass alone. |          | Grass and Oil-cake. |          |
|                        | Unsewaged.   | Sewaged. | Unsewaged.          | Sewaged. |
| Casein ... ..          | 3.246        | 3.241    | 3.352               | 3.423    |
| Butter ... ..          | 3.604        | 3.430    | 3.657               | 3.707    |
| Sugar of milk, &c. ... | 4.405        | 4.218    | 4.561               | 4.689    |
| Mineral matter ... ..  | 0.753        | 0.776    | 0.740               | 0.771    |
| Total solid matter ... | 12.008       | 11.655   | 12.310              | 12.590   |
| Water ... ..           | 87.992       | 88.335   | 87.690              | 87.410   |
| Total ... ..           | 100.000      | 100.000  | 100.000             | 100.000  |

and this in one notable case was a subject of litigation in a court of law, on account of the injury done to the trade of a milk company by the frequent and rapid decomposition of milk supplied from a sewage farm. It is also worthy of note that nowhere, to our knowledge, has the keeping of cows upon a sewage farm been a profitable success. It was abandoned by Mr. Marriage, at Croydon, after a very persevering trial, and it was in like manner abandoned at Rugby by Mr. Campbell, who thus spoke of it in a letter to the *Times*, on the 18th of August, of 1869. Twelve Ayrshire cows which calved about the same time (in May, 1869), were fed on Italian rye-grass, grown on sewaged land, and at the end of twelve weeks he found that the quantity of milk averaged 9½ quarts per diem for each cow, and each cow consumed 1½ cwt. of Italian rye-grass, exclusive of other fodder. If they had been milked for nine months, the average yield of milk would have been only from 5 to 6 quarts each cow. Now the cost of the grass was 10s. per cwt., or 9d. per cow per day, and the dairy expenses were 6½d. per cow per day, making in all, 1s. 3½d. per cow; but the milk at 8d. per gallon was only worth 1s. 7d., and when the cost of sending it to market is considered, and the wear and tear of cans, he very properly asked—where is the profit? Again, in the recent report by Mr. Morgan of the last year's operations at the Lodge Farm, Barking, where the sewage costs nothing, and where it is not taken continuously, but is drawn from the main Northern outfall in such quantities, and at such times as is thought best for the land and the crops. The balance sheet is not encouraging; for although the farm is not intended as an example of how sewage can be purified, but how it can be profitably utilised, and is worked entirely for this purpose, yet the returns on the 162 acres have been only £485 above the outgoings—and these do not include any account of remuneration to Mr. Morgan, or of the value of the sewage employed, or of the interest of capital invested. "If," says the *Standard*, in its comments on this subject, "a farmer could obtain all his manure without paying for it, there can be no doubt that his balance-sheet would be greatly improved. But if we debit the Lodge Farm with the sewage used upon it (622,324 tons on 162 acres, or 3,808 tons per acre per annum), even though we charge as little as a half-penny per ton, the profit is reduced to a very shadowy amount. At a penny a ton there is a loss of £1,268, while at two-pence per ton makes the loss equal to £3,860." Even reckoning the increase in the value of stock (£840 on £4,608 of the previous year) the profits are far from hopeful. In fact, the main features of Mr. Morgan's reports are excessively large crops and excessively low prices. He gives, indeed, a very doleful account of the market value of the farm produce. Cabbages, for instance, were sold at from 3d. to 4d. a dozen as a maximum price, the minimum being but 6d. for five dozen. Scarlet runners fetched only 3d., 6d., and 1s. a sieve in the early part of the season, and from 2s. to 2s. 6d. in the latter, and potatoes, although largely in demand, were actually sold at from £2 to £4 10s. a ton. All this had but one signification, for if general prices were ruling high as ever, the quality of the farm produce must have been remarkably inferior.

Mr. Gladstone has recommended a grant from the Royal Bounty of £300 to the children of Dr. Livingstone.  
 Dr. Liebermeister, of Basle, has been appointed Professor of Pathology and Therapeutics at Tübingen, Dr. Immermann of Erlangen, has succeeded him as Professor of Medicine.

But although the chemical composition of the milk does not seem to be very different in the two cases, yet experience has shown that the milk from sewaged grass is more apt to turn or become sour than that from unsewaged,

## The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, NOVEMBER 22, 1871.

### LAW v. SURGERY.

THE out-come of the legal performance in which the Irish Medical Profession has taken so prominent a rôle is calculated, we think, to inspire its members with a feeling of just pride and self confidence, and we are satisfied to believe that this feeling, now that events come to be considered in a calmer spirit than they could be under the influence of Mr. Butt's legal cobweb, and Mr. Falkiner's scurrilous rhodomontade, is widely spread throughout the extern-professional mind.

We are not concerned to discuss the minutiae of the attack and defence in the medical evidence. It is one of those subjects on which men can hardly judge fairly, and without bias, as long as the air is clouded with political smoke and, perhaps, personal feelings. We look only to the net result, and we are happily impressed with the consideration that that result has been an entire acquittal of the Profession. There never was, nor ever will be, a surgeon or a case which could not be made the subject of quite as good a defence under the wonderful ingenuity of such a man as Mr. Butt. Mr. Stokes has, therefore, not the least occasion for surprise or, indeed, regret that his practice as a hospital surgeon was subjected to such criticism.

It was the forlorn hope of the defence to discredit Mr. Stokes's surgery, and such a man as Mr. Isaac Butt would have quite as successfully gibbeted Sir Astley Cooper or Sir William Fergusson if it was part of his case to do so; but now that the purposes of the legal ruse have been served, Mr. Stokes's reputation survives the process of worrying, of which it was his great misfortune to be the victim, without the least taint upon it, which a week's freedom from legal miasmata will relieve it of. If political, religious, and personal prejudices be eliminated from the judgment of the Profession, we believe we may speak for surgeons of all nationalities in saying that Mr. Stokes's treatment of Talbot was such as a skilful hospital

surgeon, under similar circumstances, might adopt, and that the charges of recklessness or *mala fides* were a barefaced lawyer's dodge, as insolent as they were foundationless.

The whole legal process was, without doubt, inconceivably humiliating to Irishmen and the Irish Administration of Justice; the studied disrespect of the prisoner's counsel for the Judges on the Bench; the disreputable snarling between the advocates on either side; the importation by mistaken scrupulousness of one of the judges of a fog of irrelevant evidence, and the utterly incomprehensible verdict at last, are all tangible facts which must make all men think seriously of the future of Irish justice.

Leaving them for discussion in a more fitting place, we leave the case with a word on a medico-ethical point, which we think ought not to be left open to dispute. Dr. Robert MacDonnell was sharply cross-examined as to whether he had assisted at the operation for the removal of the bullet with the object of showing his inconsistency in doing so, if he had, as he said, disapproved and dissented from the procedure. We cannot see how Dr. MacDonnell should have acted otherwise; for, it seems to us that, as long as he believed that the surgeons in charge were acting up to the best of their judgment and experience for the benefit of the patient, he could not do otherwise than give his assistance to the carrying out of the treatment on which they decided. If a consultant were to take his hat, and leave the operating room, whenever his own opinion was not concurred in by the surgeons present, there would be an end to co-operation and consultation altogether.

## THE HAMPSTEAD HOSPITAL ENQUIRY.

### SPECIAL REVIEW.

(Prepared expressly for the MEDICAL PRESS AND CIRCULAR.)

No. III.

THE investigation into the missing child, Elizabeth Bellue, has served only to bring out the risk which is incurred by an institution of having an inmate escape from its confinement, whether the motive be intolerance of that confinement which the requirements of sanitary regulations prescribe, or whether a less excusable motive dictates the escape, or the inducement held out to the unwary to elude the vigilance of the officers, whose special duty it is to note and to verify every egress from the building.

We are aware that the possible escape of an inmate, whether adult or child, is a risk schools, institutions for training, hospitals, or religious establishments must anticipate and provide against; but we are also aware that the jealousy entertained by the English of anything like compulsory restraint, would certainly inveigh bitterly against those constructions of buildings or close guardianships, which would reduce to a *minimum* the chance of escape. The children of a vast metropolis, who are admitted at home to a great liberty in traversing the alleys and streets of their neighbourhood, are not afraid of straying, and a very little inducement suffices to “tempt them out.” This at once opens the special danger which besets this case. The child is missing from an hospital. The parents complain

that they do not know where the child is. It must therefore be found. But how is this to be accomplished? The first suggestion is,—“Offer a reward sufficient to make it worth the trouble of the neighbours or the police to find the child.” But Dr. Brewer, M.P., the able and indefatigable chairman of the Asylums' Board, very forcibly pointed out that the natural answer to this is that such a proceeding would be a direct premium to the unscrupulous to repeat the offence, and an inducement to the “employed” to connive at the repetition of the abduction. Certain it is that if gold is to be obtained from those authorised to administer the law for a direct violation of the law, the law can be no protection to the community.

When application to Mr. Justice Brett was made to issue a *mandamus* to compel the managers to produce “the body of the missing child,” he might well look with some surprise at being asked to take a step which assumed that the managers had “knowingly detained the child and imprisoned it without cause shown” (see 16 Car. 1, c. 10), and had thereby incurred the penalty of a *præmunire* (31 Car. 2nd, c. 2). The objection to this desired conclusion is that no title of evidence was produced before Mr. Justice Brett to give even a colourable pretence to such an insinuation. The fact of a child being missed from the hospital is one thing; the insinuation that the managers or their officers retained the child without cause shown is quite another, and a very serious criminal charge, which courts of judicature are not in the habit of assuaging or taking for granted.

The protest against the Local Government Board appointing a tribunal to investigate into the defects (if any) in the checks appointed by the managers upon the ingress and egress of patients, is based on an entire misapprehension of the relation that Board bears to all local or district boards for the management of the sick poor.

The protest against the refusal of the Local Government Board to pay Bellue's legal advisers is also based on a misconception of the actual stage at which the case of the missing child had arrived. The fact of the child being missed from the hospital is not disputed. No counsel learned in the law was needed on that point. The case then is one for the police and the parents, for what is now wanted is to detect the criminal or the person who seduced the child from the hospital and still keeps her from her parents. When the detectors of crime have found out the criminal, then the man of law may come in and assist in bringing him to justice.

In the meantime there is comfort in the following summary of facts:—Elizabeth Bellue was admitted in the second stage of a very modified form of small pox after vaccination. She never required medical treatment. She was very soon convalescent, and as such sent to the Islington Wards. She did not suffer any secondary attack, and was not reported sick. She had once before wandered when under parental care, and was found by her father at a Police Court. Very active steps are being taken to find out where she is, and as a detective has already traced out every person admitted and discharged, and verified the accuracy of every account of burial, we entertain well-founded hopes that when all hope of reward has been given up by the parties concerned in the offence, the child will be found. One last word of comfort. Application has already been made at the office to know what the office would be ready to give to the man who should find out the child's hiding-place.

## SCOTLAND.

**PUBLIC HEALTH.**—The deaths of 2,476 persons were registered in the eight towns of Scotland during the last month, of whom 1,186 were males and 1,290 females. This is the greatest number recorded during any month of October since the Registration Act came into operation in 1855. Previous to this month the greatest number in October was in 1868, when 2,298 deaths were registered. Allowing for increase of population, the present number is 199 above the average for the corresponding month of the last ten years. A comparison of the deaths registered in the eight principal towns, shows that during October the annual rate of mortality was 16 deaths per thousand persons in Aberdeen, 23 in Leith and in Perth, 28 in Edinburgh, 29 in Glasgow, 30 in Dundee, 31 in Greenock, and 32 in Paisley. Of the 2,476 deaths registered, 1,079, or 43 per cent., were of children under 5 years of age. In Perth, 28 per cent. of the persons who died were under five years of age; in Paisley, 34 per cent.; in Edinburgh, 35; in Dundee, 40; in Aberdeen, 43; in Leith, 44; in Greenock, 45; and in Glasgow, 49 per cent. The zymotic (epidemic and contagious) class of diseases proved fatal to 654 persons, thus constituting 26 per cent. of the mortality. This rate was greatly exceeded in Dundee (43·5 per cent.), from the prevalence of small-pox, and in a less degree from that of diarrhoea and fever; and in Leith (39·5 per cent.), from the prevalence of small-pox and scarlatina. The most fatal of the epidemics was scarlatina, which caused 134 deaths, or 5·4 per cent. of the mortality. In Greenock, Edinburgh, and Leith, the mortality from this disease was respectively 16·8, 11·2, and 7·7 per cent. of the deaths. Fever caused 121 deaths, or 4·8 per cent. of the mortality. Of these 47 were attributed to typhus, 43 to enteric, 28 to relapsing, and 3 to infantile remittent fever. Small-pox is greatly on the increase, 88 deaths being ascribed thereto, against 47 during September. This disease was most prevalent in Dundee, where 63 deaths occurred, being 20·9 per cent. of the mortality, and in Leith, where 9 deaths occurred, being 9·9 per cent. of the total deaths. In the eight towns, 85 deaths were caused by diarrhoea; 69 by whooping-cough; 44 by croup; 40 by measles; 30 by diphtheria; 10 by metria; 5 by dysentery; and 1 by cholera. 46 deaths were attributed to apoplexy, 62 to paralysis, 120 to diseases of the heart, 63 to hydrocephalus, and 121 to premature birth debility. The deaths from inflammatory affections of the respiratory organs (not including consumption, whooping-cough, or croup) amounted to 468, or 18·9 per cent. of the mortality. Those from consumption alone numbered 267, or 10·7 per cent. 84 deaths resulted from violent causes, of which one was a suicide, and another that of a domestic servant, aged 29 years, from “poisoning by yew,” in “less than 12 hours.” The yew berries are very tempting to the eye at this season, but are deadly poison. One death was caused by delirium tremens, and three others by intemperance. Two males and five females had passed the 90th year of life, the eldest being the widow of a house proprietor, aged 94 years.

### UNIVERSITY OF EDINBURGH.

**FALCONER MEMORIAL FELLOWSHIP.**—This fellowship, which is of the annual value of about £100, tenable for two years, has been conferred on Mr. William Stirling, B.Sc. The fellowship was founded in 1869 for the encouragement of the study of palæontology and geology, and is open to graduates in science or medicine of this University of not more than three years' standing at the time of the competition.

**BAXTER NATURAL SCIENCE SCHOLARSHIP.**—This scholarship, vacant by the appointment of Mr. William Stirling, B.Sc., to the Falconer Memorial Fellowship, has been conferred for one year on Mr. Alexander Hodgkinson. The fellowship is of the annual value of about £60, and is awarded to the most eminent of the Bachelors of Science who have passed their examinations in the natural sciences, including experimental philosophy and chemistry,

either in the year preceding a vacancy or in the year in which a vacancy occurs.

**THE FEMALE MEDICAL STUDENTS.**—The Senatus of the Edinburgh University, by a majority of one, have resolved to recommend to the University Court the rescinding of all the existing regulations in favour of the admission of female students, reserving to those ladies who commenced study on the strength of them all their rights. This resolution does not appear to have discouraged the female students and their friends. The General Committee for Promoting the Medical Education of Women has appealed to its friends for funds requisite to prosecute vigorously whatever measures may become necessary in the present position of affairs.

**MR. DISRAELI** has been elected by a large majority Lord Rector of the University of Glasgow. His opponent was Mr. Ruskin.

## Notes on Current Topics.

### Thoracentesis.

A VERY interesting discussion on this operation lately took place at the Clinical Society of London. Opinion was much divided, but perhaps the majority leaned to the early performance of the operation.

### A Curious Calculation.

THE late war is estimated to have cost France, in pounds sterling, 260 millions. If that sum were payable in gold, the *Siècle* says that it would represent 2,096,250 kilogrammes in weight; which, placed in cases of one-hundred kilos each, would require 20,962 cases, and 209 waggons to carry them. Placed side by side, the 325,000,000 gold pieces of twenty francs would extend over 5,000 miles, or about the distance from Havre to Havannah.

### The Medical Evidence at Kelly's Trial.

WE have great pleasure in publishing the following important document, which was, we hear, drawn up in the house of Sir James Paget, Bart. :—"The undersigned, having carefully considered the evidence in the recent trial for the murder of police-constable Talbot, and believing that certain statements made during the trial are likely to affect very injuriously the professional reputation of Mr. William Stokes and the surgeons who acted with him, desire to record their opinion that the bullet-wound in the neck of police-constable Talbot was the direct and sole cause of his death, and that no blame can be justly assigned to any of those by whom the wound was treated.—Cæsar H. Hawkins, William Fergusson, T. B. Curling, James Paget, Prescott Hewitt, J. Ashton Bostock, John Eric Erichsen, John Birkett, George Pollock."

### Oxygen in Disease.

WE commenced last week the republication of a series of instructive cases that have appeared in our able contemporary, the *New York Medical Journal*. We invite the careful attention of our readers to these clinical records of cases in the Long Island College Hospital, where the inhalation of oxygen has been tried with care and discrimination. They constitute a very important addition to the therapeutics of oxygen, to which we propose to refer hereafter, but first of all we think it well to furnish our readers with the cases themselves.

### Western Medical Advance.

**DR. LATHROP** has begun under this title the issue of an illustrated quarterly medical journal, of which we have received No. 2, but not No. 1. It contains a coloured lithograph of nine medicinal plants, indigenous and naturalised in the States, and the letter press gives an account of these as well as other interesting matter.

### Alleged Falsification of Poor-House Drugs in Ireland.

A COMPLAINT of the quality of the cod-liver oil supplied to the Waterford guardians having been made, the representative of the firm of Messrs. Hunt and Co., Dublin, the contractors, attended a recent meeting of the guardians to make an explanation relative to the matter. He said the contractors had purchased the oil from one of the most eminent manufacturers in Belgium, who supplied all the medical houses in Dublin with the article, and he was unable to conceive how it could be of bad quality. The oil complained of was part of the last consignment received, and the only difference he could detect between the sample and stock was a slight paleness in the colour. He could only account for this paleness by supposing that the oil, through mistake, had been put into a damp jar, a thing very rarely occurring. The board considered the explanation satisfactory.

### Opium Growing in the United States.

IT is stated by the *Philadelphia Ledger* that in the neighbourhood of Nashville the poppy has been cultivated for the last three years, with a view to the manufacture of opium. Owing to the lateness of the planting and inferior value of the soil, the crop of 1870 failed, and to obviate this difficulty, seed was obtained from Calcutta and Smyrna, at a cost, in gold, of 4½ dollars per ounce. This year's crop, it is announced, will yield from 60 to 75 lbs. of opium per annum. Other persons who are extensively engaged in the cultivation of the poppy in Tennessee report similar success.

### A New Pharmacopœia for the German Empire.

A COMMITTEE of twelve has just commenced its sittings at Berlin, under the presidency of Dr. Houssele, to draw up a new Pharmacopœia for the German empire. The committee includes four professors of *Materia Medica*, and medical councillors and apothecaries to represent the various States. The committee has also the assistance of experts, as Privat-Docens, Oscar Liebreich, Professor Schwanert, etc. It has been determined, notwithstanding the opposition of the professors, to continue the adoption of the Latin language, although in South Germany the German has been long employed for this purpose. The *Chemist and Druggist* understands that the committee proposes to have the new Pharmacopœia printed by the 1st of January next; and although the time seems short, it does not follow that prompt decision and continuous labour will produce a worse book than the dilatory machinery which took nearly seven years to perfect the British Pharmacopœia.

It is rumoured that M. Nélaton is expected in England shortly. It is said that he will permanently settle in London.

### Railway Dust.

MR. SIDEBOTHAM, F.R.A.S., has given an account of a microscopical examination he had made of dust blown into a railway carriage in which he was travelling near Birmingham. "With two-thirds power in microscope, the dust showed a large proportion of fragments of iron, and on applying a soft iron needle I found that many of them were highly magnetic. They were mostly long, thin, and straight, the largest being about 150 of an inch, and under the power used, had the appearance of a quantity of old nails. I then with a magnet separated the iron from the other particles. The weight altogether of the dust collected was fifty-seven grains, and the proportion of those particles composed wholly or in part of iron was twenty-nine grains, or more than one-half. The iron thus separated consisted chiefly of fused particles of dross or burned iron, like 'clinkers;' they were all more or less covered with spikes and excrescences, some having long tails, like the old 'Prince Rupert's drops;' there were also many small angular particles like cast iron having crystalline structure. The other portion of the dust consisted largely of cinders, some very bright angular fragments of glass or quartz, a few bits of yellow metal, opaque white and spherical bodies, grains of sand, a few bits of coal, &c. I think it probable that the magnetic strips of iron are laminae from the rails and tires of the wheels, and the other iron particles portions of fused metal, either from the coal or from the furnace bars.

### Pharmacy in Norway.

A VERY interesting review of the condition of pharmacy in Scandinavia, published in the *Chemist and Druggist*, informs us that the pharmacy of Norway, Sweden, and Denmark, is in each case under Government regulations. In each country these vary slightly, but not sufficiently to be worthy of elaborate distinction. Of course the respective Governments limit the number of pharmacies, and those in existence are consequently of considerable value. In the three countries there are not 400 chemists' shops. London alone contains three times as many. To take Norway as an example. In Christiania, with a population of a little over 60,000, there are seven. In Bergen, which contains nearly 30,000 inhabitants, there are three. Trondhjem contains two or three "apotheks," and this in Norway, completes the list of towns which have the very barest chance of forming a "Chemists' and Druggists' Association." In Denmark and Sweden, which are more thickly, or rather less thinly, inhabited than Norway, there are more chemists, but not so many in proportion to the population. In Copenhagen, for instance, there are 175,000 people and thirteen chemists. All the chemists' shops are distinguished by a sign. The name of the proprietor seldom or never appears. "Svane-Apotheket," "Elephant-Apotheket," "Löve-Apotheket" (the swan, the elephant, and the lion), are the favourite signs, and invariably a well-executed representation of the distinguishing animal surmounts the entrance. There is no display in the windows, unless it be a chemical balance or some other apparatus of a scientific character. The shops are always large, excellently fitted, and almost invariably two steps up from the pavement. While you are waiting for your medicine to be prepared there is no

perfumery spread before you to tempt your cultivated nostrils, no patent medicine, with labels of luxuriant eloquence, to indulge your well-trained mind. Medicine only; nothing but medicine. In the large establishments there are several dispensing counters, and the assistants are all busily employed. The doctors of course do no dispensing, except in the remote country districts, where no apothecary is near.

### Sanitaria in India.

THE new sanitarium for the Central Provinces at Puchmaree, has been found healthful and successful, so this may become a new centre of English enterprise, like Darjeeling and the others.

### Instruction in Science and Art for Women.

THE course of lectures by Professors Huxley, Guthrie, and Duncan, on the "Elements of Physical Science," will commence on Saturday next, in the lecture theatre of the South Kensington Museum, at half-past two o'clock, and will be continued every succeeding Wednesday and Saturday at the same time. These lectures form a part of a system of instruction in science and art, especially designed for women.

### Army Medical Retirements.

It is reasonable to suppose that in the midst of the changes which are revolutionising the army for better for worse, the Medical Department should live in a state of great uneasiness as to the future of its members. The first hope which Mr. Cardwell's proceedings have inspired is, that the long-standing dead-lock in army medical promotion may at last be brought to a termination, and some means devised to cause the rank and file of the department to move on a little more quickly than it has done. *The United Service Gazette* of last week asks in the cant phraseology of the day:—

Will our readers be surprised to learn that there are at this moment forty Assistant-Surgeons in the service with over fourteen years' service, 130 with over thirteen years' service, and 190 with over twelve years' service! Three hundred and fifty gentlemen out of an establishment, the entire numbers of which do not much exceed a thousand, are thus kept throughout the whole prime and flower of their manhood, suffering all the sickening pangs of hope deferred, and paralyzed in their energies and professional zeal by a system which sends scores of them to the grave without having had a single taste of the sweets of promotion. Will it be thought possible that there are a hundred Assistant-Surgeons in the Army over forty years of age, having had fifteen years of active practice in their profession, and therefore obliged to vegetate on a few shillings a day at a time of life when in civilian practice they would have been earning their thousands!

*The United Service Gazette* has its panacea, which though extremely unpalatable to those who have a belief in the dignity of years and long service, seems to us the only possible escape from the present most unfortunate repletion of the service. *The Gazette* says:—

Mr. Cardwell has in his warrant provided that henceforth Lieutenant-Colonels and Majors shall only have five years' tenure of their position. Let him apply a similar principle to the Army Medical Department, and promotion will begin to flow at a much more satisfactory pace than it exhibits at present. The average service of Inspectors and Deputy-Inspectors is over ten years, just twice as

long as it should be, and if we look at the ages of these gentlemen, the number of years they have been in the Service, and what is worse, the number of years they have been taken away from the study of a science which makes new discoveries every day, we think we establish causes much more imperative than the promotion of the Assistant-Surgeons for the relegation of these gentlemen to the *otium cum dignitate* of an earlier retirement. At present to use a colloquial expression, the Inspectors and Deputy-Inspectors hold on "like grim death," and an instance occurred not very long since when a man of about forty-four years' service rather than retire, went out for his third or fourth tour of duty in India. It must be said, however, in fairness, that this tenacity is not altogether without palliation. The Army Medical Department, being one for which the officers must qualify by hard work, is mainly filled by poor men. The doctors also are generally family men, and the existing scale of retirement would be too great a fall from full pay for any poor family man to encounter. They can at present after twenty years retire on £227 per annum, but to obtain this they must have been passed as unfit for further service by a medical board. If the War Office would give them £300 a year without the necessity of proving themselves disabled, a very great number of those who are now doggedly blocking the line would allow themselves to be shunted.

DR. JAMES COMBS has been elected Mayor of Bedford.

MISS SUSAN DIMOCK has taken a degree in medicine at Zurich.

FROM India we learn that Dr. Metcalfe, who had the medical charge of the district of Karnal, has been thrown from his horse and killed.

A WRITER in the *Pharmaceutical Journal*, announces that pure carbolic acid may be obtained in India from a common plant there at a cost of about 6s. per lb.

THE opening meeting of the Surgical Society of Ireland is fixed for the 8th of December, at the Royal College of Surgeons, Ireland.

THE Royal Society of Great Britain has awarded the Royal Medals of the year to Mr. George Busk, F.R.S. and Dr. John Stonehouse, F.R.S.

SUNDERLAND is reported to have reached such an excessive scale of mortality, that Government has despatched Mr. Radcliffe, Medical Inspector, to investigate the causes.

OUR climate has during the past few days given another specimen of its variability. It rarely happens that we get ice to the extent of two inches so early in November, but this season, in addition, snow has fallen in some parts, as to thickly cover the ground.

THE next meeting of the Pharmaceutical Society will be held on Wednesday evening, December 6th, at eight o'clock. The following papers will be read:—"The Substitution of Proportional Numbers for Specified weights and measures in the description of Processes in the Pharmacopœia. By Professor Redwood. "Method for the Estimation of Morphia in Opium." By Mr. John T. Miller. "The Syrup and Resin of Tolu, Tincture of Cinnamon, &c." By Mr. A. F. Haselden, F.L.S.

WE hear that Mr. E. Bellamy, F.R.C.S., assistant surgeon to the Charing Cross Hospital, has retired from the contest for the office of surgeon to the Royal Hospital for Diseases of the Chest, City road. The candidates now before the governors are Messrs. T. Cooke, A. Cooper, D. Freeman, J. D. Hill, and H. A. Reeves.

THE defence in the case of the Rev. Selby J. Watson, who stands charged with the murder of his wife at Stockwell, will rest purely upon the medical evidence as to the prisoner's sanity. One of the family died some years since in an asylum, and the surgeons who examined the accused are understood to hold the opinion that he suffers from serious mental excitement.

THE *Chicago Tribune*, in an appeal to the country and the charitable world, says that "probably fifty thousand persons in Northern Wisconsin and Michigan alone have been stripped of every earthly possession by the forest fires." We also hear that many medical men in Chicago have been ruined by the fire, and that in other cities their professional brethren have offered assistance.

ANOTHER death from an overdose of chloral hydrate is reported at Leicester. The deceased was a married lady, occupying a good position in society, but suffered excruciating neuralgic pains. She always kept chloral in her room, taking a dose occasionally in order to procure sleep. One morning last week she was found dead in her bed, the half-emptied bottle showing that deceased had taken enough for twelve doses. A verdict of death from misadventure was recorded.

## SPURIOUS TEA.

ON Thursday last a deputation from the Sanitary Committee of the City of London waited on the Chancellor of the Exchequer by appointment, for the purpose of explaining the insufficiency of the law as regards the importation and sale of spurious and unsound tea. The deputation was introduced by Mr. Deputy Kelday, the Chairman of the Committee, and it was attended by the Solicitor and Medical Officer of Health. Mr. Kelday described the position of the sanitary authorities of the City, and said that although they were most anxious to put a stop to a practice which was not only notorious, but was really a public scandal—the manufacture and importation of spurious tea, yet they had hitherto failed to accomplish it on account of the imperfect and uncertain condition of the law, and they were desirous to have it amended.

Dr. Lethely directed attention to the fact that the manufacture of spurious tea in China for exportation to this country, was a recognised business, and that not only were large quantities of leaves other than tea leaves, and noticeably willow leaves, manufactured for the sole purpose of adulterating tea, but it had also become a practice to manipulate the exhausted leaves of tea already used by the Chinese, and to send them into commerce under the names of Moning Congou, Maloo Mixture, &c. Large quantities of these spurious and exhausted teas had come under his observation, chiefly at the Commercial Sale Rooms, Mincing lane, where they were publicly sold by auction, and although many attempts had been made by the sanitary authorities of the city to put a legal stop to such proceedings, and to bring the offenders to justice, yet from the peculiar nature of the transaction, and the way in which wholesale business is conducted, it was found impossible to reach the guilty parties, for not only was it difficult to ascertain who were the owners of such tea, but

it was still more difficult to gain access to the bonded warehouses for the purpose of inspecting the tea, and it was actually impossible to remove it for condemnation; in addition to which, all kinds of technical legal difficulties have been raised as to whether tea can be considered as an article of food, or drink, or provision, or even as a vegetable, within the meaning of the Act of Parliament. In illustration of this, Dr. Letheby referred to some of the proceedings of the sanitary authorities at various times. In the early part of 1866 it came to the knowledge of the Commissioners that the salvage tea from the fire at Beale's wharf in Tooley street was to be offered for sale in the City. Samples of the tea were obtained, and they were found to be either so charred by the fire, or exhausted by the water from the engines, that they were quite unfit for human consumption. Proceedings, were, therefore, taken before a justice to obtain the condemnation of the 350,000 lbs of damaged tea offered for sale, but they failed on account of technical difficulties, chiefly in the circumstance that tea was not sufficiently defined in the Act of Parliament, and could not, therefore, be called a vegetable, or an article of diet. In the month of March, 1870, 201 chests of putrid tea, called Moning Congou, and 50 chests of spurious tea, called Orange Pekoe siftings, were advertised for sale at the London Commercial Sale Rooms, in Mincing lane. Samples of these teas were obtained with great difficulty from the bonded warehouses; and the former was found to be the putrid and rotten leaves of exhausted tea that had been already used by the Chinese, and redried, and the latter consisted in great part of spurious leaves. By way of testing our powers, six chests of the Moning Congou, and nine of the Pekoe siftings were seized under a guarantee to the Dock Company, and carried before the magistrate, who condemned the former without hesitation, but who declined to condemn the latter, as it was not proved that the spurious leaves were unwholesome. While these proceedings were afoot, the rest of the tea was taken from the warehouse, beyond the jurisdiction of the City authorities, and it was found to be impossible to obtain the names of the owners of the tea. Still more recently, in the month of April of the present year, 628 chests of spurious tea were advertised for sale in the City, and although they consisted in great part of dirt and iron filings, and realised by public auction from only three farthings to five farthings per pound, yet we had no power to interfere. Under these circumstances Dr. Letheby contended that the Act of Parliament required revision, and considering that the Port of London, like every other port in the kingdom, is under the jurisdiction of many sanitary authorities, whose modes of action are not always the same, he contended that the duty of inspecting tea, and of executing the powers of the Act of Parliament in respect of the seizure of adulterated and unwholesome tea should rest with some authority having jurisdiction over the whole port. He pointed to the Custom House officers, and their machinery already in complete existence, as the best suited for the purpose; for, in the first place, they have power over the whole of the port; in the second place, they have the most perfect and intimate knowledge of incomings and outgoings of every port; in the third place they are present at the sampling of teas, and at the emptying of the chests for the purpose of taking the tare for duty, and thus they have an immediate inspection of all tea which enters the port; in the fourth place, there is a chemical laboratory with a competent staff of experts for the analysis of tea when necessary; and lastly, they have the power of refusing a permit for the delivery of any unsound tea from the bonded warehouses into commerce.

The Chancellor of the Exchequer, however, was afraid that the power would be too large and too delicate for such a class of officers, and in this he was supported by Sir Thomas Fremantle, who was present at the interview, and he recommended the sanitary authorities of the City to apply to the Home Secretary for an amendment of the law. In this manner the City authorities have, in

their endeavour to deal with a very important public question, been passed from the Board of Trade to the Chancellor of the Exchequer, and by him to the Home Office.

## Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

NOVEMBER 6, 1871.

DR. ANDREW CLARK, F.R.C.P., President.

### PLASTIC OPERATIONS.

DR. LICHTENBERG communicated two cases of rhino-plastic operations.—The patients, two females, were shown. He said that he wished it to be clearly understood that he did not bring them forward as models of the plastic art, as he was far from being satisfied with them, but to show that much might be done by the surgeon which of late years had been left to the art of mechanism, or without any interference whatever, albeit a Tiliacozzi in the latter part of the sixteenth century, and a Von Graefe and Dieffenback in the earlier part of this, will ever be remembered as foremost among those surgeons who particularly cultivated the art of relieving those deformities which being so public must be deemed among the most terrible to those who are the victims. Mrs. K., the first of the two patients, had been for some time under the treatment of Dr. Baimler, at the German Hospital, as an out-patient for tertiary ulceration of the nose, and being discharged cured, was sent to him for surgical improvement. On examination he found that the septum, the entire left ala, and also almost the entire right ala were destroyed. She was admitted into the Tottenham Training Hospital, and operated upon on 23rd March, 1871. He took a flap from the forehead, but unfortunately he was under the impression that he could not obtain a sufficiently large piece without encroaching considerably upon the scalp, and he merely formed the two ala, with the intention of providing the septum from the upper lip at a future time, but he found that the nostrils, or rather the nostril contracted to such a degree that he did not consider it warrantable to produce a new deformity with the doubtful prospect of a tolerably good septum.

The second case came under his treatment in the Tottenham Hospital, and was useful in showing what large doses of iodide of potassium could do when given in these particular cases. The patient had been at different hospitals without deriving any benefit, but directly this remedy in large doses was given the improvement was well marked, and the ulceration rapidly healed. He waited some months to see whether the disease was thoroughly subdued, and operated on the 6th April, 1871. The whole nose, with the exception of some rudiments of nasal bones was destroyed, as was shown by a drawing made before the operation. He therefore had to form a very large flap from the forehead, but the skin contracted more than he anticipated, and he thought that in these cases the flap can scarcely ever be too large, provided it can be done without creating a larger deformity in order to improve a smaller, and with safety to the patient.

MR. FRANCIS MASON remarked upon the interest of the cases, no one could help admiring them. When the pedicle was taken from the centre of the nose the supply of vessels was scanty. Was the flap applied to a raw surface or an ulcerating one? In a case at the Westminster Hospital he had made three small flaps, one above the aperture and the others from each side of the aperture, turned these over the opening and laid the flap forming the nose and taken from the forehead over them. After the patient's discharge a slight ulceration had taken place at the lip of the nose. Now the nose was broader and not so symmetrical as those shown.

Mr. W. Adams, Mr. Davy, and Mr. de Meric also joined in the discussion, and in his reply Dr. Lichtenberg said that he had made this as a casual communication, and not as a paper, and therefore it was short as could be.

The PRESIDENT, in thanking Dr. Lichtenberg, said it was a model communication; being short, practical, and well illustrated, both by the drawing, and above all, by such excellent living specimens.

## URETHRAL RHEUMATISM.

Mr. THOS. BOND then read a paper on the above subject. He commenced by observing that in his opinion it is not rheumatism at all; not being the effect of any specific poison or constitutional diathesis, and it often occurs quite independently of the acute urethral inflammation called gonorrhoea, as well as of very gouty or rheumatic predisposition, but is dependent on a local condition of the urethra, so that he calls it urethral rheumatism as being its most convenient name. It occurs in men of an anæmic or weekly condition, or when a gonorrhoea has been treated too long by copaiba or purgatives. Symptoms, dull pain in heels and ankles, with pain and effusion in knee-joints, being a sub-acute inflammation of the synovial membranes, and of the fibrous tissues about the ankles, heels, and balls of the great toes; it gradually affects the shoulders, elbows, and hands. Congestion of the sclerotic vessels of the eye is present, and the health suffers severely. Exacerbations take place with pain in the loins in the morning, followed by profuse perspirations, loss of appetite and sleep, urine scanty, tongue coated, face hectic; the limbs often become permanently contracted unless great skill and care be used in the treatment. It is most important to consider the condition of the urethra which varies considerably from profuse muco-purulent discharge to the slightest gleet fluid. *Pathology.*—The disease is not diathetic or constitutional, but it is septæmic, in fact, a chronic pyæmia. I advance the theory that the absorption of the morbid materials, whatever it may be, the process goes on continually during the course of the disease, and that the abnormal condition of the blood is not maintained by the assimilation of the new materials of the blood to its altered state, as in syphilis, but that the altered state of the blood is kept up by the daily absorption of the morbid materials from the urethra. The new blood being still assimilated to its normal state, thus as soon as the supply of the "materies morbi" from absorption be stopped the blood gradually eliminates the poison and returns to its healthy state. The peculiar immunity of women is owing to the greater thickness and coarseness of the vaginal epithelium when compared with that of the male urethra, and that they are not treated by specifics and antiphlogistics. If the disease were a rheumatic urethritis and not a urethral rheumatism as some pathologists maintain, why should not women be equally liable with men? They are equally liable to rheumatism. *Treatment.*—Antiphlogistics, copaiba, and iodide of pot. do no good, in fact they do harm. The proper treatment is full diet, with steel and quinine wine and porter, and lastly, injection until the discharge is completely cured. A very good one is tannin and opium with water, by which a gallo-tannate of morphia is held in suspension. It is very good in chronic discharges, as the astringent material when injected is precipitated into the sides of the urethra, and remains for some time in contact with the surface diseased. *Deduction.*—That urethral rheumatism is a slow form of pyæmic poisoning, due to the local disease of the urethra, and that when the discharge is thoroughly and permanently stopped the rheumatism may soon be cured, and has no tendency to return, except by access of a fresh urethral discharge.

An animated discussion took place, in which Mr. Adams, Mr. Brudenell Carter, Mr. de Meric, Mr. Davy, and Dr. Carpenter took part.

### EDINBURGH OBSTETRICAL SOCIETY CONVERSAZIONE.

THE opening of the 31st session of this Society on the 8th inst., was inaugurated by a *conversazione*, in its hall, 5 St. Andrew's square. The invitations issued by the President and Fellows, included the names of the practitioners in the city and county, and most of the corresponding Fellows in Scotland. In addition to the Fellows of the Society present, we observed Professors MacLagan, Lister, Spence, Sanders, Balfour, &c., Drs. Littlejohn, Thos. Keith, Dyce, J. Smith, Hoyne, Mach, Caddell, Inglis, Higgislop, Orphor, Roberts, John Duncan, Thompson, Wright, &c., Messrs. Aytoun, Anstie, Gardner, Alnan, Hepburn, J. W. Hoyne, McKay, Nicol, Swanson, Tait, Wilson, Hilliard, Young, M. Gregor, &c., and amongst those from a distance were: Drs. P. A. Young (Portobello), Fowler (Castlphine), Brodie (Liberton), Hope (West Calder), Carmichael (Barritsland), Caruthers (Craraard), Fergusson (Peebles), Professor Wilson (Glasgow), Drs. Kerr, R. N. (Brunyrigg), McArthur (Austruther),

McFarlane (Pidmont), Parker (Nova Scotia), Robertson (Lander), Thompson (Inveresk), Thorburn (Ivanhead), Turnbull (Coldstream), McLeod (Ben Rhydding), Ballantyne (Dalkith), Forrest (Stirling), Monro (Glasgow), Black (Coehburnspalt), Whiteford (Greenock), Laurence (Montrose), Brotherstone (Aloa), &c., &c.

The guests were received by the President, Dr. Charles Bell, who opened the proceedings by introducing Dr. Keiller to the meeting, as a former President of the Society, who had been selected by the council to deliver an address. The subject chosen by Dr. Keiller was, the "Progress of Obstetrics." The time allowed for the lecture did not permit of the lecturer going deeply into the subject. He therefore took a comprehensive but necessarily cursory glance of the great subject, dwelling occasionally on some of the more important steps in the progress of obstetrical science. He also referred to the dangers the accoucheur and surgeon were occasionally exposed to in the exercise of their duties from actions being raised against them for mal-practice, but time did not permit him entering upon the merits of the recent case at Stockton-on-Tees, in which he gave evidence for the defender. Referring to the success of ovariotomy, he alluded in complimentary terms to the grand results of an Edinburgh operator, Dr. Thomas Keith, and before concluding, paid a tribute of respect to the memory of Simpson, a name ever well received in this Society.

On the motion of Professor MacLagan, seconded by Dr. Turnbull, of Coldstreams, a cordial vote of thanks was awarded to Dr. Keiller for his interesting address, the company then adjourned to another room where refreshments were provided, and instruments and preparations were exhibited.

Amongst the exhibitors connected with the Society were, Professor Simpson, Dr. Keiller, Dr. Matthews Duncan, Dr. Macdonald, Dr. Young, Professor Inglis (Aberdeen), and Dr. Ritchie. Professors Sanders and Fromer exhibited a series of preparations of injected uteri and placenta of the lower animals. Mr. Arch. Young exhibited the utero abdominal support and pessary of Dr. Charles Bell, a new midwifery forceps with one solid blade, by Dr. Hamilton of Falkirk, Dr. Cappin's bayonet jointed forceps with long and short handles, a new hysterotomy by Dr. Coghill, Professor Inglis, short handled forceps, Dr. Matthews Duncan's cephalotribe, and also his hollow sound and syringe for injecting the uterus, &c. Mr. Mackenzie exhibited Dr. Gordon's new forceps with locked handles, and moveable blades, Mr. Hilliard exhibited a variety of obstetrical instruments and apparatus. Mr. Gardner exhibited Simpson's, Churchill's, Duncan's, Grigler's, Coppie's, Keiller's, Barnes's, Campbell's, Oldham's, Greenhalgh's, Murphy's, Blendell's, Robertson's, Graily Hewitt's, Davis's, Rambotham's, Denman's, and Assitine's forceps; Simpson's, Weiss's, Holme's, Lee's, perforators; Simpson's, Murphys's, Conquest's, Holme's, Grigler's, Churchill's, cranioclasts, and Simpson's, Duncan's, Barnes's, and Charles's, cephalotribes, &c. Mr. Hart showed electrical apparatus, an ingenious invalid's bell, and the apparatus for the application of the constant current. After a very pleasant evening, the company separated about 10 o'clock.

### OBSTETRICAL SOCIETY OF IRELAND.

THE Obstetrical Society of Ireland held its first meeting on Saturday evening last, at the King's and Queen's College of Physicians.

The President, Dr. KIDD, delivered the opening address. He congratulated the Society on entering their thirty-eighth annual session in a prosperous condition. "We have," he said, "a goodly roll of members, our finances are in such a condition as to allow your Council to think themselves justified in undertaking that which they have long desired—the publication of an annual volume containing a full report of the papers read at our meetings, and of the discussions that take place thereon, and our proceedings indicate vigour, progress, and good and faithful work."

After a brief summary of the papers read during the session, he remarked that it seemed to him that such as theirs are working best, and exercising the highest functions belonging to them, when their proceedings reflect the progress being made in the departments of knowledge for the cultivation of which they were founded, and, at the same time, add their share to this progress. Judged by this standard our

Society is working well, and this I hold to be no mean praise, for in no department of medicine has more rapid and gratifying progress been recently made than in that of obstetrics.

He then entered into a brief examination of some of the subjects in which this progress has been most marked, beginning with the treatment of tedious and difficult labours. He laid before the meeting a table formed from data obtained from the five published reports of the Rotunda Hospital. He showed that during the last three years Dr. Geo. Johnston had used the forceps once in every 14.74 cases delivered in the hospital, whereas Dr. Joseph Clarke, who was master from 1787 to 1793, used it but once in 728 cases; and one of his successors had stated that he had tried it once and failed, and would not try it again. Dr. Collins used it once in 608 deliveries; Dr. Charles Johnson once in 106.88; Dr. Shekleton once in 68.74; and now we have Dr. George Johnston using it once in 14.74.

It was then shown by a comparison of the results obtained that this frequent use of the forceps was an important improvement. In making this comparison it was confined strictly to the class of tedious and difficult labours. It appears that Dr. Clarke used the forceps in but 6.55 per cent. of his cases of this class, and the perforator in 26.77, and that 20.21 per cent. of the mothers died.

Dr. Collins used the forceps in 6.66 per cent., and the perforator in 37.61 per cent. of his cases, and 16.76 of the mothers died. Dr. Chas. Johnson used the forceps twice as often as either—viz., in 13.12, and the perforator in only 20.07 per cent., and the mortality of the mothers was not more than 8.49 per cent.

Dr. Kidd next compared the reports of Dr. Shekleton's practice and Dr. Geo. Johnston's, placing them in a group by themselves, because they differed in construction from the others. Dr. Shekleton used the forceps in 32.56, and Dr. Geo. Johnston in 75.27 per cent. Dr. Shekleton used the perforator in 19.26, and Dr. Geo. Johnston in only 4.41 per cent. of his cases. Dr. Shekleton lost 6.03 per cent. of the mothers after tedious and difficult labours, Dr. Geo. Johnston 7.38. It is evident thus, that Dr. Geo. Johnston used the forceps in very many cases in which Dr. Shekleton would have used the perforator, and it seems probable that the increased maternal mortality is due to this cause, and the fact that the perforator was only used in 4.41 per cent. of the cases, and that the mortality rose to 16.66 per cent., shows that this instrument was used only in very extreme cases. Taking the whole five reports, however, the total mortality of the mothers after tedious and difficult labours ranges as follows:—20.21, 14.76, 8.49, 6.03, 7.38, per cent., and of those delivered with the forceps 50 per cent., 28.57, 14.70, 3.57, 6.86, per cent., and this Dr. Kidd claimed as a very important and marked progress in the right direction. Again, of the whole number of children born after tedious and difficult labours, Dr. Clarke lost 72.38 per cent., Dr. Collins 42.80, Dr. Charles Johnson 46.33, Dr. Shekleton 32.68, and Dr. Geo. Johnston 9.59 per cent. Of those born by the aid of the forceps, Dr. Clarke lost 50 per cent., Dr. Collins 35.71, Dr. Charles Johnson 50, Dr. Shekleton 11.90, and Dr. Geo. Johnston 4.90. In a large proportion of Dr. Charles Johnson's cases, the children died from the use of ergot of rye, a remark that applies also, though in a less degree, to Dr. Shekleton's cases; but notwithstanding this, there is here demonstrated a very important saving of infant life—Dr. Clarke's loss being 72.38, and Dr. Geo. Johnston's 9.59—in addition to the saving of the mother's lives, in consequence of the early use of the forceps—a further proof of progress.

The history of this change in practice was then traced. Progress, he said, is generally so gradual in its growth that it is impossible to say where it begins, and what are the stages of its development; but in the present instance it is not so. We have seen that it was the teaching of Dr. Clarke that almost entirely banished the forceps from the armamentarium of the Irish Obstetrician; but great as was his authority and influence, there was found one among his pupils to protest against the erroneous teaching of his master—Dr. John Beatty, Dr. Clarke's first assistant in the hospital. Since then, the use of the forceps has gradually become general in Dublin, to which the influence and example of Dr. Thomas Edward Beatty and Dr. Churchill have much contributed, for not only did they teach the use of the instrument in the hospitals under their care, and in their writings, but by their improvements in its construction

they rendered its application more easy and safe. In the Coombe Hospital the same principles have long been taught, and we all rejoice now to find the great institution to which the Dublin School of Midwifery owes so much of its reputation, the Rotunda Hospital, taking its rightful position in the van of the movement.

In private practice, he said he believed the forceps is now used with pretty much the same frequency as in the hospitals. In his own practice, he finds he has, during the last seven years, in cases that have been under his own care from the beginning of labour, used it at the rate of once in every sixteen cases. In his earlier career he did not use it nearly so frequently, but he believed the results he had obtained fully justified the change.

During these seven years he had never lost a mother from tedious and difficult labour, where the case had been under his own care from the beginning, nor had there been one child still-born that did not show indisputable evidence of having been dead some time before labour began. During these seven years he had only given ergot of rye, to hasten labour, to one patient; and he never used the forceps without having the approval, presence, and assistance at the operation of another practitioner; for, however he might differ from Dr. Clarke and Dr. Collins in other matters, he quite agreed with them in this—that no operation should be undertaken in midwifery without a previous consultation. During the same seven years he performed craniotomy but once, on a patient who had been under his own individual care from the commencement of labour, and then merely to save the mother from a prolonged labour, when the child was known to be dead. It would be difficult for him, he said, to describe the pleasure it afforded him to look from time to time on children now growing up who were born by the aid of the forceps, but who so recently even as when he was a student would have been the subject of craniotomy.

Improvements in embryotomy was the next subject taken up. It was shown that, though the use of the perforator and the frequency of embryotomy has been gradually reduced to a minimum, this very circumstance, instead of causing the operation to be neglected, has led to its improvement. Embryotomy is now only performed in extreme cases, and consequently the instruments that served well enough in cases of little difficulty, soon had their inefficiency made manifest when they came to be used only in cases of great deformity. The improvement of the instruments and of the methods of operating, therefore, became a necessity, and to this object has been directed the attention of obstetricians in all lands. In Italy and in France, in Austria and in Belgium, in America, and at home, improvements have been suggested. The *cephalotribe*, the *forceps tarière* of the Brothers Lollini, and the operation of sphenotresie of Hubert, and the dividing of the head into segments by the saw forceps of Van Heuvel, and by the *céraseur* of Barnes were described; and Dr. Kidd went on to say, "We have thus got at our disposal various methods of reducing the head or other parts of a child in utero to such dimensions that it may be drawn through a very narrow pelvis; and I claim it as another example of progress that by some one or other of these methods in those cases where the pelvis is so deformed, that some years ago we would all have admitted that delivery could only be effected by that most fatal operation, the Casarian section, the child can now be removed with comparative safety to the mother."

Dr. Braxton Hicks' method of version by combined external and internal manipulation was next described, and then those cases of transverse presentation in which it was found impossible to effect version were spoken of. In these cases Dr. Kidd said "this impossibility of turning the child had," to use the words of Denman, "to the apprehension of writers and practitioners left the woman without any hope of relief." Some proposed to decapitate the child under these circumstances, but owing probably to badly devised methods of doing it the operation was seldom if ever practised, and another operation was adopted instead. This operation, ovisceration, was seldom accomplished, according to Dr. Collins, under two hours; in one case he spent two hours and a half at it, and Dr. Kidd had seen others and had himself been as long at it. It is to the operator two hours of hard work and great fatigue, and if it produces great exhaustion in him what must it be to the mother. After a series of attempts the operation of decapitation has

colouring matters of logwood or barwood. The colours it produces with cloth mordanted with iron and alumina, are finer and more stable than the logwood colours. It is the first of this group of colours that has been produced artificially.—*Deut. Chem. Ges. Ber.*

## CARNINE.

THIS is the name applied by M. Weidel to a crystallisable base procured from extract of meat. Voit says the "Genufsmittel" (strength-enhancing), is not due to the presence of creatine and creatinine. Carnine the new base, given in doses of 1 or 2 grains, affects the nervous system and slackens the pulse.

## ON THE ACTION OF CHLORIDES ON CALOMEL.

MR. MICHAEL CUMMINS says that calomel is not converted into corrosive sublimate by soluble chlorides at the temperature of the body; but near the boiling point of water it is slowly converted into that salt. This is particularly the case with sal ammoniac. When chloride of sodium is used in place of chloride of ammonia the calomel does not so readily become converted into chloride, but requires a higher temperature. At 110 deg. no change takes place, but when kept at 120 deg. F. for twelve hours, the calomel is slowly converted into corrosive sublimate. The addition of muriatic acid seems to hasten the action. With nitro-muriatic acid the change takes place spontaneously, and at ordinary temperatures.

## BROMIDE OF CERIUM.

MR. C. BULLOCK prepares this salt by dissolving carbonate of cerium in hydrobromic acid (*American Journal of Pharmacy*). This solution of bromide of cerium decomposes while evaporating, and disengages acid fumes. When evaporated to dryness and powdered, the salt has a slight chocolate colour, and the taste is sweet and very styptic. It is very deliquescent, and nearly all dissolves in alcohol of 45 per cent. There is an insoluble sediment, which, from the author's description, seems to be oxide, resulting from the partial decomposition. In speaking of the substance M. Wurtz says in his "Dictionnaire de Chimie," that it forms a deliquescent mass, fusible without alteration out of contact with the air, but decomposed by heat in the form of air into bromine, which is disengaged, and an oxybromide of cerium. This salt of cerium is used in the American practice.

## ALUM IN BREAD.

FOR the detection of this sophistication Mr. Moffat recommends that a tincture of logwood should be made by adding 120 grains of logwood to 8 ounces of spirit, and macerating 18 hours. Such a tincture when brought in contact with bread or flour free from alum produces a pale yellow or straw colour, but when it is present a dark red shade is produced.

## PREPARATION OF SULPHURETTED HYDROGEN GAS.

MR. GALLETY recommends the use of paraffin or paraffin oil for the production of this gas in the laboratory. He simply heats equal parts of paraffin and sulphur in a flask to a temperature a little above the melting point of sulphur. A stream of the gas can thus be obtained, lasting several days; and the production of the gas stops on the withdrawal of the heat.

## ETHERIAL SOLUTION OF QUINIA FOR SUBCUTANEOUS INJECTION.

THE neutral sulphate of quinia is not soluble in any extent in water, and the use of an acid salt for the above mode of administration is attended with great pain and inflammation. It is said that one part of quinia is soluble in sixty parts of æther, but Mr. Rice, in the *Chicago Pharmacist* states that a solution in æther suitable to subcutaneous injection is easily procured contains 1 grain of the alkaloid in 2 minims of æther. This is effected by dissolving the moist quinia at the instant of its precipitation, in the presence of the æther. The ætherial layer is separated, and contains the whole of the quinia. For the details of his process the reader is referred to the *Pharmacist* of September.

## CASTOR OIL.

M. O. POPPS in *Archiv. d. Pharm.* says that castor oil is the only fat oil that turns polarised light to the right.

## CHLORAL HYDRATE AND COD LIVER OIL.

CHLORAL hydrate is soluble in cod liver oil when warmed, 10 grammes should be dissolved in 190 grammes with the aid of a sand bath.

## SUPERSATURATED SOLUTIONS.

THE principle enunciated by M. Coppet to attain this object consists in dissolving the *anhydrous* salt in cold water. The powdered salt must be added in small quantities at a time and the whole must be protected from atmospheric dust. The original paper is published in the *Chemical News*.

## Correspondence.

## THE FOG ABOUT DISINFECTANTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The article on the "Medical Aspect of the Franco-German war," which appeared in your issue of the 15th inst., after showing that the copious use of substances commonly classed among disinfectants, such as carbolic acid, was inadequate to prevent pyæmia, ends with the query, "Is it not now far too much the fashion to trust to them" [disinfectants]? Considerable practical experience in the use of disinfectants, and some personal knowledge of the way in which disinfecting measures were carried out in the German and French military hospitals, entitle me to take exception to your dubitative question. I should be disposed to blame the faulty practice pursued, for the absence of good results rather than the inefficacy of disinfectants in general. In the German hospitals which I had the opportunity of visiting, I often found two incompatible substances in use. Wounds and dressings would be sparingly disinfected with permanganate solution (Condy's fluid), made by dissolving permanganate of potash crystals, which were kept in small stoppered phials like the most costly drugs, while the utensils, latrines, wards, &c., would be treated with carbolic acid. As to the French hospitals, they seldom possessed any permanganate, and so little were French surgeons acquainted with the valuable properties of that substance, that a considerable quantity, which was sent over to Paris as a gift, before the German siege, by the principal English maker, was not used at all, and was returned intact from the Palais de l'Industrie when the war was over. Now, permanganate and carbolic acid are diametrically opposed to one another; the former being of an oxidating nature, whereas the latter is an agent greedy of oxygen. To exhale into the atmosphere carbolic acid at the time when permanganate solution is being employed, is equivalent to adopting, at considerable expense and trouble, a means of rapidly consuming the active principle (oxygen) of the latter compound. Neither in German, French, nor yet in British hospitals and ambulances, did I ever hear of permanganate having been used except in conjunction with some incompatible so-called disinfectant. Had it been exclusively employed, I am satisfied that the results would have been very different. Carbolic acid is, moreover, not only incompatible with permanganate solution (Condy's fluid), but antagonistic to ventilation, which also is a process of oxidation; whereas the latter preparation, having oxygen for its active principle, is in harmony with ventilation and a powerful complement of it.

The universal prevalence of pyæmia in the hospitals and ambulances during the war was therefore, in my humble opinion, not due to trusting too much to disinfectants, but was owing to the defective practice of disinfection on the part of surgeons and hospital authorities. When oxygen, in the concentrated and active form in which it exists in permanganate, on the one hand, and, on the other, in that of free air, shall have been given full scope with no beneficial result, it will be time enough to despair of the efficacy of disinfectants, properly so-called, for the prevention of pyæmia and other hospital scourges.

Yours obediently,

BUSYBODY OXYGEN.

London, Nov. 17th, 1871.

## TWIN BIRTHS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A recent communication to your journal on a case of twin-birth is very interesting, and narrated with singular naivete, no apology being offered for the extraordinary Fabian policy pursued by the doctor. That it chanced to be successful

is no reason why it should be allowed to pass without censure. He says "he suspected that a second child remained in utero after the birth of the first, but he 'knew' that the placenta was retained;" yet what does he do? He gives ergot. So far right—if he knew the presentation; but no uterine action following on its administration, he, after two hours, departs, leaving the woman to her fate. For anything his letter shows, he sees no more of her for three days, when he is sent for, and finds the feet presenting. Lucky it was not the arm. His manifest duty in the case was to have introduced his hand into the vagina in order to confirm or correct his surmise. He should have ruptured the second bag of water, and brought down the foot by gentle traction. The passages being already dilated by the birth of the first child, he could have completed the delivery in a few minutes without any aid from nature, but it is probable that pain would follow from the rupture of the amnial sac. If it was the head that presented, he might, after rupturing the bag of water, deliver by the forceps if it were near enough, or very easily, while the waters were prevented from all escaping by his arm, run his hand within the uterus along the body of the child, seize a foot, and turn, bring down the foot and complete the delivery. Had it been a hand or arm, this course would of course be compulsory not merely optional. The letter does not say that any examination was made to determine the presentation. In a case like the one narrated, which occurred in France some years ago, a twin having been retained in utero, metritis and peritonitis set in, the uterus fortunately became adherent to the abdominal parietes, which suppurated, displaying a cavity communicating with the womb, and revealing a decomposing fetus. I forget if it was full term or not. Using disinfecting poultices for a while, the medical attendant very cautiously enlarged the aperture with the knife, and extracted the body of the infant and the placenta. The woman recovered, but it was almost as miraculous as the recovery of a man who got a bullet in his brain. If your correspondent's first suspicion as to the existence of twin pregnancy was shaken by the non-appearance of labour pains after two hours' delay and exhibition of ergot, it was then his bounden duty to remove the placenta, for a retained placenta will most likely cause death by hæmorrhage, as in a case of concealed birth I had to do with, where it was retained for a week, or otherwise by bringing on typhoid fever or pyæmia. If he felt any hesitation as to the course to be pursued, he should have called in a consultant, a privilege too seldom availed of by dispensary doctors. Apologising for the length of this *critique*,

I am, Sir, yours faithfully,

FRANCIS M. LUTHER, M.D.

Cappoquin, Nov. 15th, 1871.

## Medical News.

**Royal College of Surgeons of England.**—At meetings of the court of examiners, on Thursday and Friday, the following candidates passed the required examinations for diplomas, and were admitted members of the college, viz.:—Messrs. David P. James, Narberth, South Wales; Thomas Harrison, Stafford; Thomas Jago, Saltash, Cornwall; Stanley A. Gill, Torquay, Devon; John Selwyn Cowley, Upton-on-Severn; Joseph Priestley Smith, Edgbaston, near Birmingham; Stanley A. Julius, Mortlake, Surrey; George Hughes Cable, Greenwich; William Ewart, Brompton; James Alexander Hendry, Liverpool; Frederick Philipps Johnston, Taunton; John H. Thomas, Carmarthen; Alfred P. Boon, Delemare crescent, W.; Edward Sergeant, Preston; Alfred R. Lee, Tollington park, N.W.; Edward Yate, Godalming, Surrey; Henry Eugene de Meric, Brook street, W.; William Cave Head, Lewes; Frederick Arnold Lees, Meanwood, near Leeds; John Samuel Slater, Bath; George John Scale, Merthy Tydfil; James Magill, M.D., Queen's University, Ireland, Cork; George Frederick Masterman, Croydon; Ebenezer Erskine Sloane, M.D., Queen's University, Ireland, Lisburn, county Antrim; Alexander Harbinson, M.D., Queen's University, Ireland, Newry, county Down; Ebenezer John Ramsey, Queen Anne street, W.; William Richard Rogers, M.R.C.P., London, W.; John Rowland Wright, Leicester; and William Johnson Walsham, Tyndall place, Islington.

**Apothecaries' Hall of London.**—At a court of examiners held on the 16th instant, Messrs. Ethelbert Hosking of Woburn square, Henry Parkhouse of Braintree, and Charles Edward Whittington, of Tuxford, having passed the necessary examinations received the L.S.A. diploma:—Messrs. Frederick William Lewis (Middlesex Hospital), Thomas Decimus Paradise (Guy's Hospital), Alfred Warren (Charing-cross Hospital), and James Sealey Whittaker (Guy's Hospital) passed the primary professional examination.

**University of Cambridge.**—*Scholarships.*—Trinity College offers one or more scholarships of the value of £80 a year for Natural Science. The examination will be on April 5th, open to all persons under the age of twenty-one. St. John's College offers an exhibition of £50 a year. The examination on April 12th, in Chemistry, Physics, and Physiology, will be open to persons under twenty not members of the University, and to under graduates in their first term. The tutors of the College will supply further information.

**University of London.**—The following are the candidates who passed the recent second M.B. examination:—*First Division*:—William Henry Alchin, James Barry Ball, William Ward Carr, Alfred Henry Carter, University College; Ernest Alfred Elkington, General Hospital, Birmingham; John Henry Humphreys, Gen. Hos., Birm. and Univ.; Richard Clement Lucas, Henry Edward Southee, Guy's Hospital; Robert Wishart Lyell, King's College. *Second Division*:—William Barnett Burn, B.Sc., Alphonso Elkin Cumberbatch, St. Bartholomew's Hospital; Frederick Durham, Joseph Theodore Ingoldby, Guy's Hospital; Alfred William Harding, B.A., Henry Newell Martin, B.Sc., Charles Read, William Wynn Westcott, University College; William Smith Paget, Liverpool Sch. and Univ. Coll.; Alfred John Wall, St. Mary's Hospital.

At the recent Pass Examinations for the diploma of membership of the Royal College of Surgeons, ninety-seven candidates presented themselves; namely, forty-six for the double examination on Surgical Anatomy and the Principles and Practice of Surgery, and also the Principles and Practice of Medicine; nineteen on the first part only; three on Medicine, having previously passed in Surgery; and twenty-nine who, having passed a medical examination elsewhere, were only examined on the Surgical portion.

**Mr. Cordy Burrows** has been re-elected for the third time mayor of Brighton.

**Making the most of a Misfortune.**—A man with a curious malformation is visiting the hospitals and selling photographs. He has two hands and lower arms on one side, so joined that the fingers of the one act in opposition to the fingers of the other.

**Proposed Memorial to Dr. Priestley.**—A public meeting was held on Thursday in Birmingham for the purpose of adopting measures to establish a memorial to Dr. Priestley. Mr. S. Timmins presided, and in the course of his remarks stated that it was proposed to purchase a portion of the site of the house at Fairhill, near Birmingham, where Dr. Priestley resided for eleven years, the house itself having been burned down after Dr. Priestley went to America. It was further stated that the response to the movement would be so hearty that something like £3,000 would probably be raised, and in that case the memorial would be made to partake of a national character by the foundation of the Priestley Scholarship for the support of a student of science at some public scientific institution. Ultimately it was decided that all these objects should be included in the project—namely, the purchase of the site, a scholarship, and a statue. A committee was appointed to take the necessary steps.

**Frozen to Death.**—Such is the melancholy announcement which reaches us as having happened on Saturday last to a member of our profession. The deceased, Mr. F. B. Eaton, L.R.C.P., M.R.C.S., was the medical officer to the Nuneaton Union, Warwickshire, and had practised in the town of Nuneaton about five years. On Friday, at twelve o'clock, he left Nuneaton, in company with a tradesman named Palmer, to visit a patient at Sutton Cheney, about six miles distant from the town. After dining, Palmer went out shooting into some neighbouring fields, leaving Mr. Eaton in the house talking with his patient. In the evening they all visited the house of a friend, named Cooper, and subsequently returned to supper. About ten o'clock the deceased started home alone

with his horse and trap. According to the evidence of Palmer, given at the inquest on Saturday night, the deceased was quite cheerful when he left; and although he had not travelled the neighbourhood previously they considered he would be able to find his way. Nothing more was seen of the deceased until eight o'clock on Saturday morning, when a labourer, named Bailey, who was passing along the road observed the deceased sitting upon the ground, his head resting upon one of the wheels of his trap and one of his arms being between the spokes. Bailey then ran home and told his master, who went immediately, and after asking the deceased several times for his name and address, the latter with some difficulty told him who he was. Brandy was at once procured, but the deceased was unable to swallow it. He was then taken home, but died very soon after his arrival. Superintendent Austin, who examined deceased's clothing, gave evidence showing that deceased must have got into some water during the night, his clothes being saturated, and some of them frozen and stiff. In the lane not far from Red Gate, a water-course is crossed by a bridge, and it is supposed that after deceased had passed over, he discovered that he had lost his way, that he then turned his horse round, got into the water, and was pitched out. The splash-board of his trap was broken. It would appear that he got in again and drove on for some distance, and, not being acquainted with the locality still went the wrong way. Mr. Nason, surgeon, who was called in, said he found the deceased quite cold and unconscious. He breathed at long intervals five or six times, and then died. The symptoms were those which would arise from exposure to severe weather. There was an abrasion on both legs from the knee to the ankle, but no other wound to account for death. The jury returned a verdict to the effect that "deceased died from congestion of the brain; consequent on exposure to cold.

Professor McGraw, of the Detroit Medical College, in an address to the graduating class (*Detroit Review of Medicine*) says: "I have been in doctors' offices where a skull grinned from one corner, ghastly anatomical plates hung from the walls, and splints, suggestive of broken bones were placed conspicuously in every corner. What a delightful resting-place for a sick woman, visions of death, disease, and injury, greeting her on every side! Now, gentlemen, make your offices pictures of comfort and cheerfulness. Banish from them every sign of your professional occupation, so that your patients may enter them not only without disgust, but with actual elevation of heart. I think, I need hardly say, that your apartments should be scrupulously clean, although I can recollect too many rooms occupied by physicians, whose windows were festooned with cobwebs and dead flies, and whose floors were stained with tobacco spit. I have been pleased sometimes to hear the occupants of such offices groan about the lack of custom, for if it is the duty of a physician to preach the virtues of cleanliness, he should himself be a living example of his own doctrine. Filthiness in a physician is, like dishonesty in a merchant, the very worst of sins."

**Medical Students.**—Dr. Ogle, the recently appointed Government Inspector of Anatomy, reports that there are this session 368 medical students in the provinces, being an increase of eleven over the number of last year, although only two schools show an increase, viz., those of Manchester and Bristol.

Total 368 357

The total number of metropolitan students pursuing their studies this session is 1,491 against 1,317 last year, or an increase of 174, the number of new entries or freshmen being 472.

#### Infirmary or Hospital?

A SINGULARLY common error is pointed out in the use of the terms *infirmary* and *hospital*, by the editor of the *British Medical Journal* (May 27th, 1871), which is, however, mainly

confined to England and this country. A *hospital* is defined as a place for shelter or entertainment, for the exercise of "hospitality," while an *infirmary* is the place for the reception of the sick. The error is traceable in London to St. Bartholomew's and St. Thomas', which were founded as priories, afterwards became hospitals, and have now become infirmaries, though still called hospitals. They might with equal propriety be called priories. In Scotland and Ireland, however, the term infirmary is correctly used. Thus, there is the Edinburgh Royal Infirmary, with 585 beds; the Glasgow Royal Infirmary, 547 beds; Aberdeen Royal Infirmary, 300 beds. The same journal suggests the change of name of St. Thomas' to that of "the Victoria Infirmary." Would it not be well for Philadelphians to remember this correct application of the terms in naming the new infirmaries proposed, as "The Infirmary of the Presbyterian Church," and "The University Infirmary," or "The Infirmary of the University of Pennsylvania."—*Philadelphia Medical Times*.

#### Carbolic Acid Injections in Rectal Irritation.

DR. J. D. TRASK, of Astoria, L. I., observes: (*N. Y. Med. Jour.*) "The readiness with which carbolic acid may be taken up by mucous membranes was first suggested to me by the fact that a patient, to whose endometrium it had been applied, spoke almost immediately afterward of tasting the carbolic acid in the mouth. In using it as an injection into the rectum, apart from its antiseptic influence, I have much confidence in its ability to moderate diarrhoea by its sedative influence. The anæsthetic influence of a weak solution in burns is now pretty well known to the profession. Its value for allaying rectal tenesmus is not, I apprehend, so generally appreciated. In irritations about the anus, combined with glycerine and a mineral astringent, it is invaluable, and in dysentery I have found it capable of affording great relief when dissolved in mucilage. The susceptibility to its use varies in different persons. When thrown into the rectum, I generally commence with a solution of one drop of Calvert's solution to the ounce, increasing the strength if necessary, until a feeling of decided warmth is produced by its administration, and this is followed by local anæsthesia."

#### Carbolic Acid as a Hæmostatic.

At a late meeting of the Atlanta Academy of Medicine (*Atlanta Med. and Surg. Journal*), Dr. J. G. Westmoreland called attention to the use of carbolic acid in the treatment of menorrhagia. He had recently treated two cases, in which the hæmorrhage, having continued for a week, was promptly relieved by one or two doses. He gave two grains of the acid, in half a tumbler of water, every three or four hours. His attention was first directed to the use of carbolic acid, as a hæmostatic, by Dr. Harden's recommending it in purpura hæmorrhagica. Dr. Westmoreland thought his success met with in these two cases, though not sufficient to substantiate the entire effectiveness of carbolic acid as a hæmostatic, marked it as worthy of further trial. Dr. Harden stated that he had used carbolic acid in hæmaturia and hæmorrhage of the lungs, in two grain doses, freely diluted, and found it a very prompt hæmostatic for any internal hæmorrhage.

#### Tickling Fauces in Asphyxia.

At the June meeting of the Lake Erie Dental Association (*Dental Cosmos*), Dr. Harrison gave his method of resuscitating patients who are sinking under the use of chloroform. He passes the feather-end of an uncut quill down the throat, and gives it a rotatory motion. The patient will revive instantly. It has always succeeded in this way.

#### Bromides in Epilepsy.

DR. LUTZ, in the *Berliner Klinische Wochenschrift*, (*N. Y. Med. Jour.*) states that he has employed the bromide of potassium in ten cases of epilepsy with good results. In three patients the attacks were entirely suspended for six months, in the remainder they occurred in much greater intervals. Lutz began with 1-3 grs. *pro die*, and increased gradually up to 10-20 grs. daily. The author found especial good results from the combination of the bromide of potassium with the bromide ammonium. This seems to him a fresh proof that the bromine is the active principle. Also in nervous headache the bromine did good service. One case of enuresis nocturna was promptly cured.

The bromides of sodium and iron may be often combined or substituted with advantage in this and other disorders.

## NOTICES TO CORRESPONDENTS.

DR. BUTLER, Philadelphia.—The money order system now established between this country and the United States, is likely to operate beneficially for both peoples. We thank you for first favour, and hope, through your agency, this Journal will become as popular in Philadelphia, as it is in New York, and other cities of the Transatlantic continent.

Dr. RITCHIE is thanked.

## BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

A Practical Treatise on Bright's Diseases of the Kidneys. 2nd Edition. By T. Grainger Stewart, M.D., F.R.S.E. Edinburgh: Bell and Bradfute.

On Smoking. 2nd Edition. By John C. Murray, M.D. London: Simpkin.

A Prize Essay on the Use of Tobacco. By H. Noel-Thatcher. London: Tweedie.

Transactions of the Pathological Society of London. The Clinical Thermometer: its Lessons, &c. By Z. C. McElroy, M.D.

Anæsthesia, Hospitalism, Hermaproditism, &c. By Sir James Y. Simpson, Bart., M.D. Edinburgh: A. & C. Black.

## VACANCIES.

Stockport Infirmary. Assistant-Surgeon. Salary £30, with board. Tormsham Union, Torquay. Medical Officer of Health. Salary £100. St. Mary's Hospital, Manchester. Medical Officer to visit out-door patients. Salary £60, with board and residence.

Bradford Fever Hospital. Two Honorary Medical Officers. Birmingham Eye Hospital. House-Surgeon. Salary £80, with board. Royal Free Hospital, London. Junior House-Surgeon. Board and residence free. (See advt.)

General Hospital, Birmingham. House Governor and Secretary. Salary £200 per annum, with board and residence.

Derby County Lunatic Asylum. Superintendent Physician. Salary £100 per annum.

South Staffordshire General Hospital, Wolverhampton. Assistant-Physician. Salary £100 per annum, with board and lodging.

Royal Infirmary, Edinburgh. General Superintendent. Salary £420, with £80 for house.

Charing-cross Hospital. Junior Surgeon Dentist. Honorary.

## MEETINGS OF THE LONDON SOCIETIES.

WEDNESDAY, Nov. 22.—HENTRIAN at 8 P.M.—Dr. Ward, "On Cases illustrating the Sequelæ of Ague, and Malarious Remittent Fever."

Friday, Nov. 24.—QUEKETT MICROSCOPICAL CLUB.—3 P.M. Mr. M. C. Cooke, "On Tremelloid Uredines."

CLINICAL SOCIETY OF LONDON.—8½ P.M. Papers by Dr. Anstie and Dr. J. W. Oggle.—Dr. Glover, "On a Case of Uncomplicated Aphasia."—Dr. Moxon, "On Symptoms of Cranial Tumour destroying Nerves, cured by Iodide of Potassium."—Dr. Habershon, "On Cases of Heart Disease."

Monday, Nov. 27, 8 P.M.—SOCIETY OF ARTS. The first of the Cantor Lectures. By C. Haughton Gill, Esq.

MEDICAL SOCIETY, 8 P.M. Ordinary Meeting.

NATIONAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.  
ROYAL FREE HOSPITAL.—Operations, 2 P.M.

## APPOINTMENTS.

BOTTLE, A., M.D., L.R.C.P.L., M.R.C.S.E., Resident Physician and Secretary to the General Dispensary, Birmingham.

BUND, W. A., M.R.C.S., House-Surgeon to the Devon Infirmary, Barnstaple.

CAYLEY, W., M.D., M.R.C.P., Physician to the London Fever Hospital.

HIBBERD, E., M.D., M.R.C.S., Medical Officer and Public Vaccinator for the Eastern District of the Parish of Paddington.

HUMBLE, T., M.D., Medical Visitor of the Dunston Lodge Lunatic Asylum, near Gateshead-on-Tyne.

LOMAS, W., M.D., M.R.C.P., Physician to the Finsbury Dispensary.

MACURK, W., M.D., M.R.C.P.L., Consulting Physician to the Fever Hospital, Bradford, Yorkshire.

MAWSON, Mr. W. A., Assistant Resident Medical Officer to the Leeds General Infirmary.

MADE, R. H., F.R.C.S.E., Consulting Surgeon to the Fever Hospital, Bradford, Yorkshire.

PHILLIPS, A., Resident Medical Officer to the Finsbury Dispensary.

ROBERTS, W., L.R.C.P.Ed., M.R.C.S., Medical Officer to the Coed-Talon Colliery Company, Mold.

SHANN, G., M.D., appointed by the Court of Quarter Sessions a Visitor of Lunatic Asylums in the East Riding of Yorkshire.

SUTTON, W., M.R.C.S., Medical Officer of Health for Smethwick, Stafford.

WATSON, P. H., M.D., F.R.C.S.Ed., Senior Acting Surgeon, and a Lecturer on Clinical Surgery, in the Royal Infirmary, Edinburgh, vice J. D. Gillespie, M.D., F.R.C.S.Ed., appointed Consulting Surgeon after twenty-one years' active service.

ARMY MEDICAL DEPARTMENT.—Deputy Inspector General of Hospitals. F. W. Innes, M.D., C.B., to be Inspector General of Hospitals.

Surgeon Major J. Hendley, from 7th Foot, to be Staff Surgeon Major vice T. Rudal, M.D., appointed to the 7th Foot.

Surgeon H. A. Gogarty, M.B., from 52nd Foot, to be Staff Surgeon, vice T. N. Hoysted, appointed to 52nd Foot.

Assistant Surgeon T. Rudal, M.D., from 2nd Dragoons, to be Staff Surgeon, vice Staff Surgeon Major B. Nicholson, M.D., who retires upon half-pay, with the Honorary rank of Deputy Inspector of Hospitals.

Staff Assistant Surgeon H. C. Peppin, from half-pay, to be Staff Assistant Surgeon, vice G. B. Stuart, M.B., appointed to 2nd Dragoons.

Assistant Surgeon F. H. Welch, from 22nd Foot, to be Staff Assistant Surgeon, vice E. O'Connell, appointed to 2nd Foot.

## Marriages.

ANDERSON—KEITH.—On the 2nd inst., at the Parish Church, Eston, George Henry Anderson, M.D., of Lofthouse-in-Cleveland, to Jessie, eldest daughter of Alex. Keith, L.R.C.P.Ed., of Normanby, Yorkshire.

SUTCLIFF—CLARK.—On the 9th inst., at St. James's, Croydon, Joseph Harvey Sutcliff, Esq., of Ripley, Surrey, to Katherine Jane, daughter of the late Robert Clark, Esq., of Farnham, Surrey.

## Deaths.

BROOKE.—On the 7th inst., John Brooke, M.R.C.S.E., of Stockport, aged 73.

BULLEN.—On the 11th inst., George Bullen, F.R.C.S.E., of Ipswich, aged 80.

ROWLAND.—On the 8th inst., H. O. Rowland, M.R.C.S., of Claydon, Suffolk.

WETHERHEAD.—On the 2nd inst., Thomas Wetherhead, of Prees, Shropshire, aged 55.

## MOUNTMELLICK UNION.

COOLRAIN DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.—The Committee of Management of the Coolrain Dispensary District will, on MONDAY, the 27th inst., appoint a properly qualified Physician to the office of Medical Officer of the above District.

Salary fixed Ninety Pounds per annum, exclusive of Registration and Vaccination Fees.

Applications for the Appointment to be addressed to SAMUEL WATSON Esq., Honorary Secretary, Laurel Hill, Coolrain, Mountrath.

By Request of the Committee,

ROBERT GOODBODY, Clerk of the Union.

Board-room, Mountmellick Workhouse.

9th November, 1871.

## SLIGO UNION.

SLIGO DISPENSARY.

AN APOTHECARY WANTED.—A Vacancy of Apothecary to the Sligo Dispensary having been created by the resignation of Dr. LOUGHEED, the Dispensary Committee will proceed to Elect a duly-qualified Apothecary, on FRIDAY, the 24th NOVEMBER 1871, at a Salary of Fifty Pounds per annum. Candidates are required to appear personally, and lodge their Testimonials with the Secretary, on or before One o'clock the day of election.

DANIELL MACGILL, Hon. Sec.

Sligo, November 7th, 1871.

## ENNISCORTHY UNION.

MEDICAL OFFICER WANTED.—In consequence of the resignation of Dr. SHERRIDAN, who has been appointed Medical Officer to the Wexford Dispensary, the Committee of Management of the Ouhart Dispensary District will proceed to the election of a Medical Officer for that District, at a Salary of Ninety Pounds per annum.

There is a Fever Hospital, with an excellent residence adjoining, for attendance at which the Board of Guardians allow the Medical Officer £25 per annum besides his fees under the Vaccination and Registration of Births, Deaths, and Marriage Acts.

Tenders from properly-qualified Medical Officers, accompanied by Diplomas and Testimonials, will be received by me on or before Friday, the 24th November inst., on which day, at One o'clock, the election will take place at the Dispensary House, Ballaghkeen.

Personal attendance is required.

By Order of the Committee,

NICHOLAS KEATING, Hon. Sec.

Ballinastraw, Enniscorthy, November 8, 1871.

Established 1848.  
**PROFESSIONAL AGENCY AND MEDICAL  
 TRANSFER OFFICE.**  
 50 LINCOLN'S INN FIELDS, W.C.

**J. BAXTER LANGLEY LL.D. M.R.C.S., F.L.S.,**  
 &c., (KING'S COLL.), and Author of *VIA MEDICA*.  
 Has always upon his books a large number of desirable invest-  
 ments and available Appointments for negotiation.

The business of the Professional Agency is based upon the  
 general principle that no charge is made unless work has been  
 done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.  
 Office hours, from 11 till 4; Saturdays excepted.

**PRACTICES AND PARTNERSHIPS NOW OPEN**  
 for negotiation (in addition to those advertised in Dr.  
 Langley's List, (which is sent post free on application).  
**Y 335. SAFE INVESTMENT.** Surgeon's retail in a nor-  
 thern suburb. Gross receipts nearly £400 a year, but  
 with a special opportunity for very large practice. The  
 house is situate in a thoroughfare, and the shop is well  
 stocked and fitted. The cash receipts average about  
 £1 a day. Terms £250.

**Y 333. DEATH VACANCY, LONDON.** Private Practice  
 with open surgery. The whole connection being, it is  
 believed, easily transferable. The business has been  
 neglected, yielding an average of over £500 a year,  
 upwards of £200 being derived from appointments  
 taken in cash. There is scope for upwards of £1,000  
 a year. Midwifery fees £1 ls. and £2 2s. The house  
 is held on beneficial lease, sixteen years unexpired.  
 The shop is large and well fitted. Immediate applica-  
 tion necessary.

**Y 330. DEATH VACANCY.** Dr. Langley has been  
 honoured with instructions to negotiate for the suc-  
 cession to the PRACTICE of the late Mr. Langston  
 Parkes, F.R.C.S., of Birmingham, just deceased. The  
 practice was partly special, with a good family con-  
 nection, and realised about £1,300 a year. The copyright  
 of valuable works may be included in the purchase,  
 and would afford a fine scope for a specialist in the  
 same department. A very efficient introduction can  
 be given to the private practice, and liberal terms  
 would be conceded to a suitable gentleman. Applica-  
 tions in the first instance, to be addressed to Dr. Langley,  
 as above.

**Y 329. ASYLUM.** The resident medical proprietor of a  
 large asylum in a Western County, desires to meet  
 with a gentleman to join him as partner, with option  
 of succession. The mansion stands in its own grounds  
 within sight of the sea, and is within three minutes'  
 of a railway station, and within half an hour's drive of  
 an important junction, affording communication to all  
 parts of the Kingdom. The asylum has been estab-  
 lished about thirty years, and is licensed for about 150  
 patients, male and female. About 100 are at present  
 resident. The rent of the whole, without buildings,  
 &c., is £245. The furniture may be taken at a valuation  
 at the end of the partnership. No gentleman can  
 be communicated with, unless he can give a satisfactory  
 reference as to the capital at his command.

**Y 337. PHYSICIANS PRACTICE** with a transferable  
 connection in an inland watering-place. Receipts  
 £1,000 a year. two years' partnership introduction.  
 Patients entirely upper class. The residence is large,  
 and in a commanding situation with every conveni-  
 ence. Rent £100 a year. No gentleman need apply  
 who has not high qualifications, and can give a banker's  
 reference.

**Y 338. PRESCRIBING PRACTICE IN LONDON.** Re-  
 ceipts average between £3,000 and £4,000 a year.  
 Patients of the very best class, and within a short  
 radius of the residence, which is situate in the best  
 professional district of the west end. Rent £270.  
 The connection has been long established, and a  
 thoroughly suitable gentleman could secure every pa-  
 tient by the recommendation and introduction of the  
 vendor. To secure the co-operation of a successor who  
 will be acceptable to his patients, the vendor is willing  
 to make easy pecuniary arrangements, but no gentle-  
 man can be negotiated with who has not £2,000 at his  
 present command.

## RED HEART RUM.

CELEBRATED FOR ITS GREAT AGE, SOFTNESS, and PURITY.  
 It was specially supplied to the Sick and Wounded during the late  
 War, and is strongly recommended in cases of  
 CHOLERA, DIARRHŒA, SEVERE COLD, &c.  
 Price 42s. per doz., bottles and case included. Samples can be had at  
 3s. 9d. per bottle.  
 Agent—J. G. Turney, 61 King William street, City.

## JAMES'S FEVER POWDER.

4s. 6d. PER BOTTLE, PACKETS 2s. 9d. EACH.

PREPARED and sold by J. L. KIDDLE, 31 Hunter street,  
 Brunswick square, London.

This preparation has been so extensively employed by the Faculty,  
 and its merits so universally acknowledged by the public at large, as to  
 render all further remarks on the part of the Proprietor unnecessary.  
 To be had of all Wholesale Druggists

**AERATED LITHIA WATER.**—Messrs. BLAKE  
 SANDFORD, and BLAKE are prepared to supply the LITHIA  
 WATERS (of which they were the original manufacturers under  
 Dr. GARROD's instruction) of any strength prescribed by the Profession  
 for special cases. Those in constant use contain two grains and five  
 grains in each bottle, either by itself or combined with BICARBO-  
 NATE of POTASH or PHOSPHATE of AMMONIA. Also,  
 POTASH, CITRATE of POTASH, SODA, SELTZER, VICHY, and  
 MINERAL-ACID WATERS, as usual.—BLAKE, SANDFORD, and  
 BLAKE, Pharmaceutical Chemists, 47 PICCADILLY.

COKESTOWN HOUSE, INSTITUTED FOR

**THE MEDICAL TREATMENT OF THE INSANE OF  
 BOTH SEXES.**

This highly respectable Mansion in no respect resembles, either in-  
 ternally or externally, what is usually known as an Asylum.

The Demesne, Conservatories, Graperies, and Grounds are unusually  
 extensive, and in good condition.

There are Billiard Tables for both sexes, with indoor and outdoor  
 amusements, including Vehicles.

Cokestown House is within three miles of Carrick-on-Suir Station,  
 with a like distance from Fiddown, both on the Waterford and Limerick  
 Lines, and in connection with the G. S. & W. and Kilkenny Lines.

For terms, and Form of Admission, apply to the Resident Physician.  
 JOHN PEPPARD, M.D., &c.

Cokestown House, Piltown, co. Kilkenny.

ADHESIVE STAMPS.—BILLS OF EXCHANGE.

**THE BOARD OF INLAND REVENUE** give Notice that  
 they will shortly issue to the Public adhesive stamps for denoting  
 the *ad valorem* duties payable on bills of exchange drawn out of the  
 United Kingdom, of a different colour to those now in use. The colour  
 of the stamps for the various rates of duty in shillings will be green  
 instead of purple, and those for the duties in pounds will be purple  
 instead of green.

The alteration, which is limited to these two series, will not interfere  
 with the continued use of the present stamps.

By order of the Board,  
 Wm. Lomas, Secretary.

Inland Revenue, Somerset House,  
 14th November, 1871.

## MALVERN COLLEGE.

The NEXT TERM will commence on Thursday, 25th January.

**ST. ANDREW'S MEDICAL GRADUATES' ASSOCIA-  
 TION.**—The Fifth Anniversary Session will be held at the Free-  
 masons' Tavern, Great Queen street, on Friday and Saturday, December  
 1 and 2.

On the 1st, at 7 P.M., the business of the Association will be trans-  
 acted, after which Dr. Swete will open a discussion on "Habitual  
 Drunkenness and its Treatment, Medical and Legislative."

On the 2nd, at 5 P.M., the President, Dr. Day, of Stafford, will de-  
 liver the Anniversary Address, "The Historical Steps of Modern Medi-  
 cine." The dinner will be held at 6 P.M.

LEONARD W. SEDGWICK, M.D., Hon. Sec.

**EMBALMING.**—A new and perfect system of Embalming  
 having recently been discovered, Messrs. Garstin beg to intro-  
 duce the same to Public notice. Simple as effective, it recommends  
 itself in all cases of bereavement where the preservation of remains is  
 either a necessity for transmission to foreign governments—for sanitary  
 considerations—or the various exigencies for delayed completion of the  
 funeral rites. The preparation, also wonderfully adapted for anatomical  
 purposes, is already now in use at the principal schools of medi-  
 cine. The fluid, with directions, immediately forwarded on applica-  
 tion by telegram or otherwise. The family surgeon declining, the  
 Inventor will attend to operate on reasonable terms.

Messrs. Garstin, 5 Welbeck street, Cavendish square, London. To be  
 obtained, also, through all Chemists and Druggists in the United  
 Kingdom, the Continent and Colonies. Price £2 the case.

## The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive  
 and largely increasing circulation in each of the three divisions  
 of the United Kingdom and the Colonies. Being also supplied to the  
 Hospital Libraries, &c., it will be found a most valuable medium for  
 Advertisements of Books, Vacancies and Appointments, Sales and  
 Transfers of Practices, Surgical Instruments, Chemicals, and Trades  
 generally.

When advertisements are given for a series of insertions, a very con-  
 siderable reduction from the above scale is made.

Advertisements for Insertion in this Journal must be at the  
 OFFICE, on SATURDAY, by Two o'clock.

# The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 29, 1871.

## LECTURES ON EPILEPSY

DELIVERED IN THE

LEDWICH SCHOOL OF MEDICINE,

BY HENRY EAMES, M.D., Dub. L.C.P., &c.

Physician to Mercer's Hospital, Joint Lecturer on the Practice of Medicine, Ledwiche School, &c.

(Continued from page 451.)

I SCARCELY need to tell you that the future of the epileptic presents a gloomy prospect. The hideous fits recurring from time to time excite the horror and pity of those who witness them. Added to this the dire effects of the disease on the physical and moral condition of the unhappy sufferer are but too plainly visible. The health is seriously injured, gripping pains in the abdomen, flatulency, an irregular state of the bowels and extreme lassitude are of frequent occurrence. Numbness and cramps in the extremities may come and go. Transient loss of speech and sight may be observed many times in the progress of a case. These symptoms are paroxysmal, appearing and again disappearing with suddenness. Control over the appetite is lost. They gorge themselves with food, and saturate themselves with drink. They equally exceed in the appetite of sex, and if the normal means of its gratification cannot be obtained, they have recourse to onanism. They are at once gluttons and satyrs. Some become unwieldy with fat, whilst others waste away. They rarely reach old age, and, speaking generally, madness, idiocy, or general paralysis is the doom of the epileptic.

There are, however, exceptions to this rule, you will hear quoted Cæsar, Mahomet, and Napoleon are said to have been epileptic. These exceptional cases of the disease arising in persons of the highest intellect, should not be taken for more than they are worth. They are the exceptions that prove the rule. It is true that mind and body escape serious hurt in a not inconsiderable number of epileptics; but in such the seizures are few, and separated by long intervals. It is when fit closely follows fit that

the effects on the intellect are most surely produced. Especially is this the case when, after the disease has been long in abeyance, the malady is lighted up afresh, and renews its attacks, the seizures being at short intervals. The mind does not suddenly fail, the loss is gradual, extending commonly over a long period. Hence it is often unperceived by the patient's friends. Even whilst the intellectual powers are unimpaired there is a curious mental condition induced. Savage rage, or extreme depression arise from trifling causes. The restraining influences of reason and reflection are withdrawn; impulse holds undisputed sway. Many epileptics are themselves aware of this mental flaw, Capriciousness is their leading characteristic.

Violent attacks of mania occur after the fits in some cases, to these allusion has already been made. They cease as abruptly as they commence. The mind of the patient during their continuance is a prey to terrifying hallucinations and ideas. The relation of epilepsy to mania we cannot, however, now further discuss.

Amongst the predisposing causes of epilepsy, hereditary tendency to the disease ranks preëminently the first. There is a strong probability that a parent who is epileptic will produce epileptic offspring. This is more especially true if the parent so affected be the mother. In this, as in other hereditary maladies atavism is frequently observed; that is the affection skips, as it were, a generation, and the grandparent transmits the heritage of woe to the grandchild, the parent intermediate not having manifested the disease. Again, the tendency may be hereditary, though neither parent nor grandparent have been affected, the disease being passive as it were in the direct line, whilst active collaterally, uncles, aunts, or cousins being subject to its attacks. The hereditary tendency may further be exhibited in what may be termed the convertibility of nervous disease. Thus, a parent with chorea may beget an epileptic child or *vice versa*. Similarly the children of an ataxic parent, some may be epileptic, some chronic, some colour-blind, some blind in twilight. In the descent one may replace the other, and this holds good for a series of diseases all essentially neurotic. Should there be an intermarriage of families, which from their aptitude for such diseases we term neurotic, the probability of the offspring

being affected is increased fourfold, whilst should near relations of such families wed this probability is infinitely magnified; since there is no doubt that the produce of marriages contracted between those closely allied in blood are exceedingly prone to suffer from nervous diseases, independently of original flaw in the parents or in their families. Statistics abundantly prove this statement, which especially holds good in those disgusting unions of uncles and nieces.

The children of those who have suffered from mania, of drunkards, and those exhausted by venereal excesses are not unfrequently epileptic. Females are slightly more prone to the disease than males.

The age at which, in the majority of cases, the first seizure occurs is, from the tenth to the twentieth year. This period you will observe includes the important changes of puberty. The disease arises next in frequency from the second to the tenth years, during which the permanent teeth are cut. From the twentieth to the thirtieth years epilepsy rarely originates. It must, however, be mentioned that no age is completely exempt, though it rarely attacks the extremes of life.

Of the exciting causes those connected with the mind are undoubtedly the most numerous. Cases so originating are variously stated at a third or a half of the entire number in which an exciting cause can be traced. Under the category of mental causes we place fright, terror, horror, as at the sight of a fit, anxiety, worry, overstrain of the mind. We also find as excitants of the disease neuromata, tumours and cicatrices implicating nerves, worms especially the tænia in the intestines, and abnormal conditions of the uterus. Hysteria may gradually pass into epilepsy. Coitus is the immediate exciting cause in some, both in males and females; such is asserted to have been the case of the first Napoleon. Excessive indulgence in venereal pleasure, and masturbation tend to produce the disease; markedly that form of masturbation in which, during the act the imagination is actively engaged in calling up some lascivious tableau. Physical and psychological exhaustion are here combined.

Any classification of the disease from its exciting causes must be manifestly improper, although you will see used the terms *epilepsia uterina*, *abdominalis*, &c., for in more than half the cases on record no exciting cause could be discovered. But in only one-eighth of these cases was there neither exciting nor predisposing causes.

Of none of the causes just detailed can it be predicated that it will alone produce epilepsy. In addition there must be some second and hitherto undiscovered factor, and this leads me to speak of the pathology of the disease.

The exact anatomical nature of the lesion is unknown. There is, however, a strong probability that the medulla oblongata and the base of the brain are the parts from whence proceeds the excitement of the motor nerves, spasm of the muscles being the result. The following considerations lend support to this view. The arrest of the functions of the hemispheres is proved by the loss of consciousness during the fit. It is hardly possible that motor impulses should proceed from them during this time. Convulsions, similar to those in epilepsy, are induced by the interrupted electric current applied to the medulla oblongata, whilst no motor impulses follow its application to the hemispheres. Further it has been proved by experiments on the lower animals, that epileptiform convulsions can be produced even after the entire removal of the hemispheres. The observations of Van der Kolk furnish a strong additional link in the chain of evidence, for he found the only constant lesion in the bodies of epileptics, in whom the disease was of long standing, to be dilatation of the small arteries and capillaries of the medulla, with thickening of their coats. This author believes that the convulsions depend on an increased afflux of arterial blood to the medulla oblongata. Others hold that spasm of the muscular coats of the arterioles in the same part, cutting off the arterial supply, is the true source of the disease. For convulsions difficult to distinguish from those of

epilepsy can be experimentally produced by anæmia of the brain, its arterial supply being arrested. If hyperæmia of the medulla oblongata be the cause it is not easy to understand why this afflux of blood should occur but once in six months, or twelve, and why cerebral congestion to an intense degree occurring in the intervals should not be followed by convulsive attacks. Further, how is the disease caused by tumours, cicatrices, worms, ceasing on their removal, though in other cases the disease continues despite the removal of its undoubted cause?

Various are the theories by which it has been attempted to explain the phenomena of epilepsy. The ganglia of the medulla have been compared to a Leyden jar, or to the electric organs of certain fishes, the motor force being stored up accumulatively, and discharged from time to time. It has been thought that the spasm proceeding from the medulla passes through the vaso-motor nerves, causing contraction of the arteries, and a consequent anæmic condition of the parts supplied by them. This supposition would satisfactorily account for the pallor of the face at the commencement of the attack, and for the general coolness of the surface during its progress.

Mr. Brown-Séquard believes that it is an augmentation of the reflex excitability of the cerebro-spinal axis which chiefly constitutes epilepsy, and that further changes occur in the skin, mucous membrane, &c., which render these parts capable of exciting epileptic seizures. Different traumatic injuries of the spinal cord induce epilepsy. When such injuries were experimentally inflicted on animals, he found that epileptic attacks either appeared spontaneously, or could be produced at will by irritation of certain parts of the skin. When the injury was done to one side of the spinal cord, simple irritation of the same side of the face and back occasioned the attacks. When the injury was done on both sides, irritation of either side caused the convulsive seizures.

The similarity of the symptoms produced by anæmia and hyperæmia of the brain have led some writers to the conclusion that there are two distinct kinds of epilepsy, the one due to anæmia, the other to hyperæmia of the nervous centres. This might account for the fact that accesses of the disease are prevented in some by increasing the amount of blood circulating within the cranium; whilst an opposite procedure has a similar effect in other cases. Nocturnal epilepsy generally would be classed under the anæmic variety, whilst cases in which the tongue is bitten would be considered hyperæmic, the roots of the hypoglossal nerve being congested. In the "petit mal," the hemispheres are chiefly affected, the implication of the medulla oblongata being slight and very transient.

Whatever parts anæmia or hyperæmia of the nervous centres may have in the causation of convulsions, it is to be clearly understood that there is another element present, probably undiscoverable in the present state of science, which renders epilepsy a distinct and specific malady.

I shall not longer detain you with the theoretic pathology of the malady, but now proceed to its treatment.

(To be continued.)

## CLINICAL LECTURES ON DISEASES OF THE EYE,

DELIVERED AT THE ADELAIDE HOSPITAL.

BY H. R. SWANZY, M.B., L.R.C.S.I.,

Ophthalmic Surgeon to the Hospital, and Surgeon to the National Eye and Ear Infirmary; late Assistant to the late Professor Von Graefe, Berlin.

### LECTURE II.

*Strumous, or Phlyctenular Ophthalmia.*

GENTLEMEN,—I have to present to you to-day several cases of strumous, or phlyctenular ophthalmia. It is

called strumous, because of the condition of the general health which it commonly attends; and phlyctenular, because the little vesicles, which form on the conjunctiva or cornea, as the case may be, are termed phlyctenulæ. It is a very common disease—a large proportion of the out-patients of this department of the Hospital labouring under it. Its most common victims are children between the ages of three or four, and eleven or twelve; but it is by no means uncommon in still later periods of life. In many of the text-books you will find phlyctenular ophthalmia divided under the two heads of "Diseases of the Cornea," and "Diseases of the Conjunctiva." The arrangement is very absurd, for the affection is the same whether it appear on the cornea or conjunctiva, it is treated in a very similar way in either case, and, moreover, it most frequently attacks both tissues simultaneously, or passes from one to the other. The vesicles, which make their appearance in the disease, vary from the size of a pin's head, or somewhat larger, to very small specks like grains of fine sand, which are distinguished by the naked eye with difficulty, unless when a great number of them occur close together, as is indeed usually the case.

Perhaps the most common form of phlyctenular ophthalmia is that in which the conjunctiva, close to the margin of the cornea, becomes swollen at one place, and there small points, like grains of sand, make their appearance. There is a good deal of conjunctival and subconjunctival injection of vessels in the neighbourhood, and the remainder of the conjunctiva participates more or less in the hyperæmia. At this stage there is often a good deal of tearing and photophobia. The disease may cease here, or, after a few days, we may find a number of very fine phlyctenulæ in the adjacent part of the cornea, giving it the appearance as if sprinkled with powder. If the cornea become affected, the tearing and photophobia increase.

Another common form of the disease is the solitary phlyctenula, which appears on the conjunctiva as a rather large vesicle; it may be situated at some distance from the cornea, or close to its margin. No matter how many of these may be present, they never become confluent. This form of the affection frequently produces but little irritation of the eye, so long as it is confined to the conjunctiva; when, however, one or two of these phlyctenulæ are situated close to the cornea, circumscribed opacities, are apt to be formed in the cornea itself, and we thus have one of the most frequent and severe forms of phlyctenular corneitis, attended with distressing symptoms.

A third form of strumous ophthalmia is the broad phlyctenula, situated on the conjunctiva, usually at some distance from the cornea. It is uneven on its surface, appearing to be formed of an aggregation of small infiltrations. It is much rarer than the two forms I have already described to you, and it is less frequently associated with corneitis; but, on the other hand, it is more apt to strike deep, and produce inflammation of the sclerotic.

Still another form of the disease is termed "fascicular corneitis." Although I have seen almost as many cases of this in Germany as of any of the other forms, still I have not, as yet, met with one in this country, and I shall not, therefore, confuse you by a description of it—my great object being to make you acquainted with disease of the eye as you are most likely to come across it.

I think you will find all cases of phlyctenular ophthalmia referable to one or other of the forms I have described. They will, of course, present different pictures according to their different degrees, according to the way in which they have been treated or mistreated, and according to the extent to which they have been neglected. Injudicious treatment may alter the natural appearance of any disease, so as to make the diagnosis difficult enough. A common error, against which you must guard, is that of confusing pustular with phlyctenular ophthalmia. The former is most frequently met with as a sequel to small-pox, and is one of the most

destructive affections to which the eye is liable, differing, thus, widely from phlyctenular ophthalmia in its prognosis. Its treatment also is quite different, and pathology will, doubtless, sometime demonstrate, that the two diseases are distinct in their nature.

The greatest danger in phlyctenular ophthalmia is, that when an infiltration of the cornea ulcerates, the process may lead to perforation of that membrane. This is, however, of comparatively rare occurrence. What we commonly have to fear, are opacities of the cornea, left at the places where infiltrations and ulcers were situated. Even mild cases of phlyctenular corneitis frequently leave opacities behind, which may be recognised with the aid of the oblique illumination. The more severe cases, however, accompanied with intense infiltrations, particularly if these had assumed a purulent character, are apt to leave white opacities behind, which are very disfiguring, and very detrimental to vision.

I wish now to explain to you what is known of the pathology of phlyctenular ophthalmia, before we consider its treatment. It is only lately, indeed, that anything has been made out on this point, for, as you may suppose, it is not easy to get preparations of such a disease, in order to examine it microscopically. Professor Iwanoff, of Kiew, in Russia, had the good fortune to obtain three specimens of phlyctenular ophthalmia, *post-mortem*, of which he has shown me the microscopical preparations. These demonstrate\* that the phlyctenulæ are collections

of small, round cells, lying immediately under the epithelium of the cornea or conjunctiva. In cases of small phlyctenulæ, the epithelium covering them

\* "Klinische Monatsblätter für [Angenheilkunde." November and December, 1869, p. 462.

remains normal; in the larger ones it is usually destroyed (*i.e.*, commencing ulceration). The membrane of Bowman, on which the phlyctenulae in the cornea lie, was always found normal. You may perceive in these drawings the remarkable path by which the cells arrive between Bowman's membrane and the corneal epithelium, namely, along the course of nerve filaments, which pass from the deeper parts of the cornea, and penetrate the membrane of Bowman to reach the epithelium. You are, of course, aware that the cornea, and especially its superficial epithelium, is richly supplied with nerves. This course of the cells along the nerves is interesting, as it explains, by pressure on these filaments, the blepharospasm so frequently present, and which is often referred altogether to phthophobia, attendant on the affection. If the distressing sensations of the patient were merely owing to the fact that the light hurts the eye, they ought surely to disappear when he is placed in a dark room. This is, however, not the case, for the blepharospasm is then alleviated only, but does not cease altogether. The blepharospasm must be regarded much rather as a reflex action, caused by irritation of the corneal nerves, in a manner similar to that by which an ordinary nictitation is produced. Iwanoff did not make out from whence the cells originated. In appearance they are similar to lymph corpuscles.

You will find little difficulty in the treatment of mild cases of phlyctenular ophthalmia; the instillation of a few drops of atropine, with the insufflation of a little calomel, and protection of the affected eye from exposure, will in a few days suffice for the cure. Not so, however, those cases which are attended with severe phthophobia, pain, and lachrymation, all denoting extensive infiltration of the corneal tissue. If I could paint a picture of a patient with a severe attack of this kind, it would be a child of seven or eight years of age, led in by its parent, its head bowed down, and turned away from the light, the eyelids spasmodically squeezed together, the eyes covered with the hands, or the knuckles pressed into the sockets, and probably, to complete the drawing, a half-eaten piece of bread in one hand, and an apple in the other. The diagnosis of such case is apparent, as soon as the patient comes within sight. Nothing will induce the child to give us a look at the eyes, and, in order to get it, recourse must be had to force. In this state of irritation, the only treatment admissible is an antiphlogistic one, consisting in the instillation of a dozen drops or so of atropin, (*sol. sulph. atrop. gr. iv. ad. ℥j.*), in the course of the day, purges of calomel, and restraint in a dark room. The blepharospasm is a serious obstacle to the removal of this irritable condition, for it not only impedes the instillation of the atropine, but, in itself, encourages congestion of the eye, and thus sustains the morbid process. The children should not be permitted to lie on their faces, as they are inclined to do, for this also induces congestion. The antiphlogistic treatment, especially the atropine, and an attentive nurse, will soon succeed in abating this distressing condition of things; but still there are some cases which will resist.

In these obstinate cases, a seton in the temple is a favourite remedy with some of the London ophthalmic surgeons. For my own part I have no experience of the seton in phlyctenular ophthalmia. I can quite imagine that it is a very effectual mode of treatment, but I cannot help thinking that it is unnecessarily severe. I have had many cases of the worst phlyctenular ophthalmia under my care, but I have not yet come across one which demanded such a treatment; nor, unless indeed the phlyctenular ophthalmia which occurs in London, exceed in virulence anything which exists in Germany or here, can I believe that such cases present themselves. When the disease resists the treatment I have described to you, you will commonly find, as I have already mentioned, that the blepharospasm is the principal enemy with which you have to contend. The infiltrations in the cornea give rise to it, and it then causes congestion of the eye, which again, in its turn, encourages the formation of fresh infiltrations, and so you have a

vicious circle, in which it is necessary to break a link before you can make any progress. We have a very simple means for the correction of this excessive blepharospasm, which was always adopted by my lamented master, Von Graefe, and which I have never known to fail, if carried out properly and systematically, namely, the submersion of the patient's face in a basin of cold water. The child is raised up by two nurses, one supporting the trunk and hands, the other holding the legs, while the surgeon takes charge of the head, and dips the face under water, holding it there for about ten seconds; the patient is then allowed to take a breath, and the same manœuvre is repeated several times. The effect of the proceeding is magical: the blepharospasm disappears, the child lies on its back, allows the eyes to be easily examined, atropine to be instilled, and becomes in every way as docile as could be wished. The process may require to be repeated after some hours in consequence of a return of the spasm, but the latter will soon be permanently conquered. When, then, you have reduced the irritation of the eye, the question of a more active topical treatment arises, and there is one application which I can confidently recommend to you, as being little short of a specific in this disease, namely, Pagenstecher's yellow ointment.\* About the size of a pea of this ointment is to be inserted between the eyelids with a camel-hair pencil, and after five minutes, what still remains of it in the eye is to be carefully washed out with a soft sponge. The application is to be repeated daily, and the beneficial effect of it will be soon observable—the infiltrations becoming absorbed, and the ulcers filling up. An important point in the use of this ointment is, that it be not employed until the irritative stage is quite passed. If this be not attended to, the irritation is increased, and all the symptoms aggravated. The effect of this first application should be well noted, and if the eye appear more irritated next day, the further use of the ointment should be postponed for a little longer. Calomel dusted into the eye is a favourite remedy with some; but I use it only in the after treatment, unless in mild cases. The instillation of atropine must be continued until all irritation has disappeared. In order to prevent recurrence of the ophthalmia, treatment, either with the ointment or with calomel, must be persisted in long after the affection is apparently cured; for, the most common cause of these recurrences is the too early cessation of the treatment. So long as the eyes are red and injected upon the patient's awaking in the morning, the cure is incomplete. A complication which may retard the cure, and cause recurrence of the affection, would be the existence of a stricture of the nasal duct; you must, therefore, be on your guard against it.

There is no doubt that this form of ophthalmia is most frequently found in children of a strumous habit, indicated, in well-marked cases, by enlarged glands in the neck, a red and bulbous nose, and a swollen and overhanging upper lip. I am inclined to think that in the Profession, the influence of the constitution upon local diseases in general is often over-estimated; and that the result of this is to encourage the error—among us, of our consoling ourselves for our inability to cure certain diseases, because they are supposed to depend upon an abnormal condition of the constitution; whereas, in fact, perhaps, the fault lies in the unsuitability of the local treatment employed, in the mode in which it is applied, or, in some local complication, which should

\* I have only been able to have this ointment properly prepared in Dublin by Mr. C. R. C. Tichborne, of the Apothecaries' Hall of Ireland. He has given me the following note of the process:—"The precipitated mercuric oxide was made by me in the following manner.—Corrosive sublimate was dissolved in hot water, and this solution was precipitated with a solution of potash. The latter should only be added until all the oxide is precipitated. The mercuric oxide falls as a yellow powder. It must be carefully washed with distilled water, and dried at 100° C. The ointment is prepared by rubbing up one part of this precipitated oxide with fifteen of unscented cold cream. If properly prepared, this is just the right consistency. It should, however, be genuine cold cream, and not what is ordinarily sold as such, which is only an ointment. That is to say, it should contain water, and be made with unbleached almond oil."

be corrected. I believe that the great thing for the cure of phlyctenular ophthalmia, and for the prevention of its recurrence, is the local treatment, and I do not think (I confess I have never seen it tried) that any constitutional treatment would alone effect the cure. At the same time, it is most important that you should attend to the general health of these patients. You must look after the digestive organs, and regulate the diet. Above all things, the constant chewing of apples, cakes, and bits of bread must be forbidden. It is a habit which is almost universal with these children, and one which is often encouraged by the parents, who think it a sign of robust health. The meals must be given at stated hours, and be of a plain and wholesome kind; but between times the stomach must have leisure to digest its contents and to rest, and dare not be kept in a state of irritation by having fresh work thrust upon it every now and then. Cod-liver oil, internally, will suggest itself to you all as specially indicated. Von Graefe was very fond of prescribing what he called Plummer's powders, containing calomel and golden sulphuret of antimony in equal parts.

In conclusion, gentlemen, I must warn you against the terrible mistake, which is prevalent, that the subjects of phlyctenular ophthalmia "grow out of it," and that it is therefore unnecessary to take any measures for its cure. And so, indeed, they do "grow out of it;" but with their corneæ in so nebulous a condition, that their future prospects are often seriously affected in consequence.

## Original Communications.

### ON THE TREATMENT OF ECZEMA.

By J. L. MILTON,

Surgeon to St. John's Hospital for Skin Diseases.

(Continued.)

*External Applications.*—In acute or very slight cases of eczema almost any mild astringent will suffice. Perhaps among the best we may rank subnitrate of bismuth in elderflower-water or camphor mixture, or liquor of the diacetate of lead, two drachms to six ounces of either fluid. When expense is not an object half an ounce of glycerine should be added, as from its faculty of retaining moisture it powerfully aids the purpose which lotions are intended to serve.\* When there is a large weeping surface, particularly in children, or of long standing in adults, the reader may try Dr. Hughes Bennett's plan.† It consists in applying a solution of carbonate of soda, half a drachm to a drachm in eight or ten ounces of water, by means of a piece of lint soaked in the liquid and laid upon the part affected. The lint must be covered with thin gutta-percha or oiled silk to prevent its getting dry, or else the management of the affair must be entrusted to the care of some person who will see that the lint is kept moist, for which purpose it should be sprinkled continuously with cold water, the lotion being only occasionally applied. If this plan be properly carried out, if the linen be kept wet all day long, and still more if this can be effected day and night, the results are often marvellous; but if it get dry the soda speedily irritates the skin. The addition, however, of glycerine, half an ounce to eight ounces of fluid, will mitigate this to a certain extent, but nothing compensates for want of attention. Dr. Wallace has re-

ported\* some cases in which the beneficial results of this plan were very marked. My experience of it is, that though it gives great relief, yet it has very little curative power, that it is only suitable for a large wet surface, and that it is apt, in eczema of the head, to give a bad cold.

In chronic eczema a lead lotion, the same as above, can be used. In many cases, where the surface is very irritable, it answers best when gently warmed previously. So soon as the discharge and inflammation are checked, zinc ointment forms an admirable dressing. It should be gently melted down, or rubbed down with an eighth part of spirit of camphor, and smeared like thin cream on the part. All surfaces to which ointment is applied should also be covered with old linen. When once ointments are begun with no more watery applications should be used, nor should the part be washed, except when the eczema is seated on the head and discharging freely, as happens sometimes, especially in children, or when in parts where washing cannot always be avoided as the hands, face, &c. At such times the discharge, when the eczema assails the head, is sometimes retained under the crusts, or the hair gets matted with it. Here it is very useful to poultice the crusts with mashed turnip or bread and water, till they are thoroughly softened, and then remove them by very gentle washing with hot water and yolk of egg, or what I prefer to anything else, the St. John's Hospital soap. Mashed turnips is the best poultice I know of; it possesses the great advantage of rapidly removing any unpleasant smell. In some cases a weak lotion of chloride of zinc, a grain to an ounce, with the addition of half a drachm of mucilage, is a very valuable application to the head; it is only here that I have found the chloride of zinc useful. But for the entire removal of eczema in the dry stage we must turn to a more potent remedy—one of the nitrates of mercury. I have never seen the oxide of zinc ointment—even that prepared by Messrs. Bell, of Oxford street, really cure this disease when severe; and I have repeatedly treated in the same patient, one patch of eczema with the dilute nitrate of mercury ointment, and one with the oxide of zinc, the result being invariably most decidedly in favour of the former; I have also made similar trials with the ointment of the nitric oxide as against that of the yellow nitrate, and am disposed to prefer the latter. Indeed, in my hands, the ointment of the yellow nitrate diluted, has proved superior to any application I have seen tried. Two or three years ago I showed several surgeons the effects of its action compared with the chloride of zinc as recommended by Dr. McCall Anderson, and the zinc ointment. Three patches were selected on the same patient, pretty nearly of like size and in the same stage. One was treated with the solution of the chloride, one with the zinc ointment, and one with dilute nitric ointment. At the end of a few days it was manifest to every one that the action of the nitrate was superior to that of the zinc ointment, and this again to the action of the chloride; and by the time that the patch treated with the nitrate was healed, that to which the zinc ointment had been applied was much better, while that treated with the solution might be roughly computed, so far as such computations hold good, at only half way towards a cure. These applications were now abandoned, and the diluted nitrate was alone resorted to, under the influence of which the progress of the two remaining patches was soon visibly accelerated.

But if the application is to be useful it is indispensable that it should be properly made up and properly employed. In the first place, pure, well-made nitrate of mercury ointment only should be selected. A great deal of that which is generally used is totally worthless, being dry, dirty green, and rancid, spoiling almost as soon as it is diluted; whereas, when properly prepared it retains its bright yellow colour for months. The dilute ointment should only be prepared when it is wanted, and the best plan is simply for the patient to rub it down with a little sweet almond oil till it is of the consistence of cream, and always

to throw away what is left. If the eruption be seated on the head in children, the hair should be cut off and the ointment applied night and morning; a linen cap should also be worn day and night. But grown persons cannot, or will not submit to this; the hair should, therefore, be parted, any crusts gently detached, and the ointment rubbed carefully, but not roughly, in, the cap being worn at night only. Should the hands be affected soft leather gloves with the tips of the fingers cut off, should be worn during the night, and, if possible, during the day also. Where there is very little hair, and the eruption is only slight, the ammoniated mercury ointment of the "British Pharmacopœia" may be tried; it is one of the cleanest and least offensive preparations that we possess, but in point of efficiency I would place it decidedly below the nitrate ointment. Some persons with a strong tendency to eczema, or after the cure of the worst part of their complaint, suffer a good deal from a chapped, red and tender state of the skin, cold cream is often very useful in relieving this. A powder composed of equal parts of finely ground American corn flour, and oxide of zinc, with camphor, dusted over the face during the day time, especially if the patient is to be exposed to a cold wind, is also of great service. Whatever theoretical objections may be made, ointments cannot be too sedulously employed in eczema even during the day, and when the eruption is seated on the face and hands. When the hair is falling from eczema, I know of no remedy so effectual as cutting it quite short, and blistering it as for alopecia. With regard to the itching I never yet saw any remedy materially affect it. The cure of the itching is the cure of the disease. The same symptom holds good of another disagreeable but rare symptom—a kind of neuralgia or rheumatism of the skin sometimes seen in eczematous patients. Mr. Wilson says he has found no remedy for it equal to a solution of nitrate of silver, a grain in an ounce of spirit of nitric ether.

Dr. McCall Anderson seems to think the lard is the chief agent in the benefit said to be effected by mercurial ointments. It happens that I not only have subjected, but am every day subjecting, this doctrine to a test; for it is a constant practice with me to prescribe, at the same time, pure lard and ointment of the nitrate of mercury, the former to be used when the nitrate sets up much irritation, and I have repeatedly had occasion to satisfy myself that the ointment is much more powerful than the lard.

(To be continued.)

## ON THE CHIEF EPIDEMICS OF THE LAST THREE YEARS.\*

By ROBERT LAWSON, ESQ.,  
President of the Epidemiological Society.

MR. LAWSON commenced his address by indicating the necessity of a close observation, not of one, but of every epidemic, over the greatest possible surface, and for a series of years, to afford trustworthy data for the determination of the general laws which govern the progress of this class of diseases in their diffusion over the earth, and illustrated the value of such inquiries by the ascertained facts with regard to small-pox, scarlatina, diphtheria, fever and cholera, not only in this country but on the Continent and in America. He gave an example from the last two diseases. In 1868 there was much fever in Asia Minor and along the shores of the Mediterranean as far as Spain, and in 1869, the disease in various forms, was very prevalent through Europe, from Madrid to St. Petersburg, while it remained very active at several points along the north coast of the Mediterranean. Fever increased at Berlin in 1870, and at Vienna a pretty severe epidemic of typhus commenced at the end of that year and continued

during the first half of 1871. It will be remembered that in 1869 malignant cholera made its appearance at Kiew, in Russia, in the summer of 1869, and towards the end of the year spread to some extent through the basin of the Dneiper, but acquired no great force until 1870, when it involved the whole country from the Black Sea to St. Petersburg, but was not met with in Europe as an epidemic west of Russia. In 1871 cholera continued at St. Petersburg and extended to Archangel, to Helsingfors north of the gulf of Finland, and along the country to the south of that and the Baltic as far as Hamburg and Altona. There had been a severe outbreak in Persia, to the south east of the Caspian, in the autumn of 1868, which continued into 1869; and in the course of that year this was to have been expected in southern Russia or the corresponding latitude in Asia; it actually appeared at Kiew, some 300 miles from the nearest sea, and 1,500 from the nearest point where the disease was known to exist at the time, while every attempt to trace its origin to importation failed. It has been found from an extensive examination of facts, that cholera, as an epidemic, will not penetrate a district occupied by an epidemic of fever (enteric excepted) until that subsides, when its place may be taken by the other. The fever in Asia Minor in 1868 and in Europe in 1869-70 and 71, seems to have limited the progress of cholera westward in these years, until it crept along the south shore of the Baltic a few months ago. It is worthy of observation that the relative distribution of cholera and fever during the first approach of the former to Western Europe in 1828-29-30 and 31 presents year by year an almost exact parallel to that in the corresponding period 1868-69-70 and 71. In 1831 a fresh wave came from the south which affected Smyrna and Constantinople, and extended into Hungary, and was experienced in this country in 1832; in 1871 a similar wave appeared in Southern Russia and has been felt at Smyrna and Constantinople and has given slight indications at Vienna; it remains to be seen whether the parallel will be completed by its becoming epidemic in this country in 1872.

## NOTES ON PHTHISIS PULMONALIS, &c.

By R. LOCKE JOHNSON,

Visiting Physician to the Infirmary for Consumption and Diseases of the Chest, Margaret street, Cavendish Square, W.

PROBABLY, within the entire field of therapeutics—vast and diversified as it is—there is no other subject so justly entitled to a prominent position in its kindred literature, nor has that position more freely accorded to it, as phthisis pulmonalis, for an universally acknowledged insinuating scourge, relentless, ruthless, and insatiable, when it once takes a firm hold on poor mortality—as phthisis in all its forms undoubtedly is—requires the undeviatingly constant caution, the anxious and actively acute observation and action, of the wardens of the people's health to battle with it ever. So its first movements, stealthy and incipient—when possible, and its subsequent destructive strides—uniformly—are followed step by step—as a consequence—by hosts from the great medical army that now garrison the globe.

That the opinion thus put forward is incontrovertible, a casual glance over the medical literature of the day and of all countries—and prolific are many pens—will convince the most sceptical.

We all know that in order to become a good soldier in the army of animal force, it is not necessary to be the wearer of gold-lace shoulder straps, nor to be a general of division. To the possessors of transcendent talents and ability, and to heroes—in recognition of valorous deeds—such distinctions should be accorded, but he of the rank and file, nevertheless, who labours with honest might—his only decoration the sublime assurance of his sincerity of purpose—is seldom an unwelcome auxiliary in the field, especially if the fight be a prolonged one, and the enemy be formidable and apparently unconquerable.

\* Abstract of the Address delivered at the Opening Meeting of the Epidemiological Society on the 8th inst.

Thus it is that the subject of phthisis is ever a leading characteristic in our medical literature. It is a formidable enemy no doubt, ever in deploy before us, ever keeping in the throbs of strategy each member of our army—from the hoary-headed and justly decorated general of division, to the *rawest* recruit we may be in a position to muster.

Being of the rank and file, and in the daily presence of that relentless enemy—phthisis—and stimulated, perhaps by its influence I place at the disposal of the MEDICAL PRESS AND CIRCULAR Editors, the following crude notes on cases treated at the North London Consumption Hospital, during the absence on the Continent of one of its most accomplished physicians, Dr. Prosser James.

These notes are of necessity incomplete, the period of time in which they were penned too has long passed; they are submitted, however, as an illustration of the fact that the enemy is being fought by some whose weapons are in verity reeds, yet we all know the story of the chance shot.

Before concluding these preliminary words, may I observe that there is one point in connection with the treatment of phthisical cases that I do not consider has received from the many great authorities on the subject sufficient attention. It is this the *increased tendency* of patients to hæmoptysis during the months of May, June, and July. Having for some years past made observations on this point, I have been in many cases enabled either to retard altogether, or to lessen the lesion by attention to the pulse, the skin, and the secretions.

#### CASE I.

W. H., single, æt. twenty-seven, barman, admitted April 1st, 1868, has been a sailor, has lost his father, one uncle, and one cousin in consumption. Has enjoyed good health up to a little before Christmas, when he felt appetite fail. Last Christmas day had severe cold, with hoarseness. Cough and pains in chest soon followed and has been getting worse ever since. Has lost much flesh. No hæmoptysis.

April 3rd.—Suffers now from troublesome cough, with greenish thick expectoration; profuse night sweats. Before admission had been treated by sinapisms, expectorants, and anodynes. Pains in chest better, and cough better since admission. Scarcely any respiratory sound over the lower half of the right side, but the voice sound is loud, and over this part there is dullness on percussion. On the left side moist crepitation over the upper half with bronchophony. Remainder of the chest gives puerile respiration. The breathing is mostly abdominal; the pulse 104.

℞ Tr. camph. co., m. xx.;  
Acid sulph. dil., m. xx.;  
Quin, dis., gr. j.;  
Aq. ʒj. ter die.

Nutritious diet, extra eggs.

April 7th.—Much the same; cannot sleep, and has suffered from night-sweats. Morph. acet. gr. 1-6th.; zinci. oxydi. gr. ij.; Extr. hyosey. gr. ij.; omni nocte, Ac. sulph. dil. m. x. x.; dec. cinch. ʒj. ter. dia.

April 8th.—Slept better without perspiration, but cough to day is more troublesome; pulse 110; a linctus ordered for the cough.

April 12th.—Breathing easier; pulse 112; cough easier; sleeps better with pill; continue linctus; use lin. tigllii.

April 16th.—Oil has brought out many large bullæ on the chest with much inflammation; breathing worse; has not slept so well; linctus.

April 18th.—More night-sweats;

April 21st.—At the right apex there is now loud blowing and whistling; cough still troublesome; no more sweating; feels stronger and more cheerful; to take two pills, one at night the other in the morning.

April 25th.—Auscultation same; cough much more troublesome; pulse 100; continue.

May 5th.—On percussion at the right apex, there is fair resonance, but at the left apex it is impaired. On auscultation at right, there is tubular jerking, uneven respiration at the left; clicking noises in the supra-spinous fossa, and supra-scapular region.

Ordered sodæ hypophos., gr. v.; aq. camph., ʒj. t. d.; rept. pil. morph. bis. die.

May 14th.—He has had for the last four days, five or six liquid motions daily; more hectic; feels very weak; pulse 110; Sod. hyp., gr. v.; T. opii., m. x.; inf. gent., ʒj. ter. die.

May 20th.—Now says has been in the habit of taking much spirit, and bought himself brandy when out for a walk. Ordered two table-spoonfuls of brandy every night in water, and forbade all other stimulants.

June 1st.—Is losing flesh rapidly; cough excessive, mostly in throat.

June 12th.—Last two nights cough has been much more troublesome, preventing sleep; has also severe night sweats; Pil. conii. co. ij.; on. rep. mist.

June 15th.—Better as to cough; otherwise same.

June 21st.—Complains of weakness of knees; tongue slightly furred; bowels regular; sleeps well; does not sweat so much.

June 30th.—At the right apex there is a loud whistling noise, and at the left, the moist *râles* are much the same.

This man remained only a short time longer in the hospital. He seemed to improve a little, and this was thought to be due to the good diet, fresh air and rest he enjoyed.

#### CASE II.

April 3rd.—J. Q., single, æt. twenty-one, labourer, with no hereditary predisposition to consumption, always good health up to last November, when he took cold, and has been ailing ever since, nevertheless, two months before that time he had had a slight hæmoptysis.

Report stated that he had disease at right apex with cavernous metallic respiration; percussion] not metallic; nothing marked posteriorly; expectoration white, frothy; cough frequent; has taken cod-oil and expectorants; don't think has made much if any improvement; has a hot, dry skin; complains of thirst and sleeplessness, with troublesome cough and expectoration; no night sweats; gave Liq. am. ac. ʒss.; T. camph. co. m. xx. ter die.: cod liver oil.

April 10th.—Cavernous metallic respiration, but no humid sounds at right apex; pectorioloquy percussion note very flat; on left side increase of vocal resonance.

April 28th.—Cough more troublesome, otherwise the same. To have Pil. conii. comp. gr. v.; night and morning.

April 30th.—To day, at right apex, *bruit de pôt fêlé* very distinctly elicited. The pectorioloquy marked, and unusual creaking noises heard in the supra-spinous fossa. Thought that the cavity was contracting—an idea confirmed by the patient's steady progress for some time afterwards—at the left apex the sounds were normal. He left the hospital in May, and attended some weeks as an out-patient, still progressing.

#### CASE III.

April 2nd, 1868.—Robert J., æt. sixteen, single, apprentice to watchmaker. No previous disease until nine months ago, when he was seized with hæmoptysis to the extent of 5½ pints in a fortnight, not much since then, mother living but has cancer of the breast, father killed by an accident. Cough became troublesome soon after the hæmoptysis, and nothing has eased it. Has been out-patient at St. Mary's. Cough now continues very troublesome; at the right side, front and back, fine moist crepitus and increase of vocal resonance; the left side is duller on percussion, but no moist sounds are heard here; he is very feverish; com-

plains of great thirst and want of sleep; pulse, 120; quick; liq. am. ac. ℥ss.; sp. eth. nit. m. xv.; tr. camph. comp. m. x.; aq. ℥j. ter die.

*April 7th.*—Appetite worse; says the medicine "rises on his stomach;" flatulence; bowels constipated; tongue red and furred on each side of dorsum; thirsty; pulse, 120; respiration, 50; to take effervescing citrate of magnesia three or four times a day; Liq. morph. m. v.; ex. inf. gent., ℥j., bis die.

*April 10th.*—Appetite better; less thirsty; stomach better; tongue clean; pulse 130; respiration 40; there is now on the right side moist crepitation at both apex and base; left dull at apex and at extreme tops in suprascapular region, find blowing with increase of voice.

*April 12th.*—Appetite better; thirst less; tongue cleaner; pulse, 120; respiration, 36.

*April 16th.*—Continues the same.

*April 18th.*—Feels better; can walk more easily; pulse very weak, rapid, 130; respiration, 36; physical signs the same; appetite better; cough not so troublesome; sleeps comfortably all night; no sweating; continue Mist. morph.

*April 25th.*—He now complains of pain at the right base, where on auscultation fine crepitation is heard; the pulse is very weak, rapid, 130; respiration quick, short, difficult, 40; affecting *alae nasi*. R Liq. morph., m. v.; pot. nit., gr. v.; pot. bic., gr. x. aq. pip. a. ℥ss., ter die; croton oil liniment to be rubbed in.

*April 28th.*—Remains same; cough and expectoration worse; the liniment has brought out much eruption; the breathing is very short; sickness has set in, and became severe after food; tongue red glazed moist at edges, with stripes of fur on each side; Mist. bism. morph. ct. acid hydrocy.

*April 30th.*—Not sick since the first two doses of medicine; tongue better; feels stronger; has been for a little walk in the sun this fine day; slept well last night for first time.

*May 5th.*—Left apex and base tubular, with prolonged expiration, no bronchophony; right moist crepitation apex and base; base seems subsiding; continue the treatment.

*May 11th.*—Remains the same; complains much of flatulence, but no more sickness; mixture of chloroform and sp. am. arom. in infus. gent.

*May 14th.*—Feels better; less flatulence, and all general symptoms less urgent.

*May 29th.*—Has been going on very well; stomach and bowels comfortable; tongue clean; appetite good; no perspirations; no thirst; skin cool; pulse, 110; respiration, 34; complains of dyspnoea, but says that is easier than before; physical signs remain same; the moist râles on right side persist, and the tubular breathing on left remains exactly as before.

He improved still further, and left the hospital to enter a convalescent institution.

## Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

NOVEMBER 13, 1871.

DR. ANDREW CLARK, F.R.C.P., President.

DR. TILBURY FOX made a very interesting communication of an

OUTBREAK OF RINGWORM IN A LARGE ESTABLISHMENT—300 CASES OCCURRED.

There was an outbreak which began in April and ended in June, to break out in September, after two months absence. As many as forty-three or forty-four cases occurred in one day in September. The disease was not re-imported. The dust of the room was collected in glass slides, it was composed of entiste epithelium and germs (sporules). Grease to the head is a most important application to prevent it spreading.

DR. SANSON communicated a case of

PHTHISIS COMPLICATED WITH ENDOCARDITIS.

Martha G., widow, æt. twenty-nine, applied 28th April, 1871. Complained of great prostration; pain generally over the chest, much cough and expectoration and hæmoptysis to the extent of half-a-pint. Her illness began three months ago. Her mother, sister, and brother died of phthisis. Prostration and dyspnoea were great. There was deficient resonance over the upper and middle lobes of the right lung, and much imperfection of the respiratory murmur. The contraction of the heart was feeble and rapid, no murmur. April 29.—Much cough towards night, but very little expectoration. She was very delirious. On auscultating the chest one found over the base of the heart a soft to and fro sound, and on carrying the stethoscope nearly to the apex a very soft diastolic murmur. It was now found that the phthisis was complicated with endocarditis; no pain in joints, but pain after coughing referred to the lower portion of the chest; the pulse varied between 123 and 144; the temperature rose from 99°8' to 103°6'. May 4.—A to and fro soft sound heard at apex. May 6.—After great suffering she died. *Post-mortem.*—Both lungs contained yellow tubercles, especially the right, where they were very numerous and varied in size, from a pea to a marble, and were for the most part infiltrated with pus. The pericardium contained a tablespoonful of dirty brown fluid, but no recent lymph; on the right verticle was a yellow patch (old deposit). The left ventricle was found almost blocked up by stringy clots; the mitral orifice was converted into a thickened ring; there was a clear history of phthisis. The physical examination was difficult, but no heart sounds were detected. After rest in bed, soft murmurs were heard, and a to and fro sound caused by commencing pericarditis with slight effusion; the diastolic murmur heard to right of apex not over aorta was no doubt mitral endocarditis present, with a question as to pericarditis; the endocarditis was the pressing mischief.

MR. BRUDENELL CARTER showed (1) a girl with embolism of the entire retinal artery. On Monday last a sudden mistiness came before the eye, and in five minutes the eye was quite blind. On Thursday there was no perception of light. The branches of the ophthalmic artery were seen radiating in different directions as fine as hairs; the veins were distended. In most cases there are small venous hæmorrhages; in this girl there was bright arterial hæmorrhage. The plug was near the lamina cribrosa, and a small vessel coming off behind the plug must have given rise to hæmorrhage. (2) Was a middle-aged man, with neuritis of both optic nerves following an injury to the head. In this case the sight was not affected much. The disc was obscure; the blow was received two years ago; two or three fits of unconsciousness on the railway caused him to leave his work. He staggers in his gait.

DR. HUGHLINGS JACKSON said that the study of the red softening visible in ophthalmic cases was most instructive. The red softening of the brain and spinal cord must be analogous.

DR. ALFRED CARPENTER, of Croydon, related the following cases of

MUSCULAR ANÆSTHESIA.

The cases were two intelligent young ladies, the daughters of a city gentleman. The elder, M. H., æt. twenty-eight, of average good general health, every function of organic life being properly performed, all the natural functions of the body being in a healthy state; has been under the care of Dr. Carpenter for the last three years without material alteration, except a gradually slow but decided decrease in muscular power. Now she cannot rise from her chair without assistance; the attempt when made with aid is clumsily and awkwardly performed; when she has gained the erect position she staggers, and is uncertain in her gait; her movements corresponding with those observed in intoxicated persons. The foot being raised from the ground there is an uncertainty as to where it will be placed, and it goes down with force, the heel first reaching the ground with a blow. As she cannot see the foot she cannot tell how far it is from the ground. She can only retain the upright position as long as she knows assistance is at hand. She has more difficulty in starting than in continuing her movements. If she stands, and is told to shut her eyes and move, or if she is in the dark she cannot remain upright, but at once falls. There is however no material loss of power, for the individual muscles are still strong, and some force is required to bend her joints

against her will, though the muscular power is much less than it was two years ago. She can still lift a considerable weight and carry it if her eyes are fixed upon it. Her sight is good, the pupils act equally and freely, and there is no defect in the co-ordinating power of the optic muscles. There is no congestion of the conjunctiva; no amblyopia. There is no want of association in the muscles of expression, but there is a slight effort required in speaking. There is clumsiness of movement in the upper extremity, for she cannot button a button or put in a shirt stud unless she looks at it. She cannot use her fingers with any precision when out of sight, but can execute drawings of considerable merit. She used to play on the piano very well, but for the last five years the requisite movements have become unsteady and imperfect. Her memory and hearing are quite right. She never suffers from pain of any kind, there are no starts or jerks or muscular tremor. Urinary organs and secretion normal. She has a lateral curvature of the spine with some flattening of the ribs on the right side in the middle of the dorsal region. The distortion, which is considerable behind, does not alter the shape of the chest in front. There is no cutaneous anesthesia, the neighbourhood of the joints is naturally sensitive. No numbness or formication in ordinary position, but if she sits up in bed with the knees drawn up before her, and a weight is kept on her knees, there is a feeling of numbness and deadened sensibility in the lower limbs, but there is no marked reflex action, and no effect follows upon irritating the soles of the feet. She is able to localise sensations excited by the use of a pair of compasses in a normal manner, though the tactile sensibility of the lower extremities is, if anything, rather lessened. She is the second of eight children; her parents are healthy. At twelve her shoulder was said to have "grown out." Dr. Little ordered a supine position, with no mental work, and daily muscular exercise. Iron supports were used for four years: The catamenia appeared at fourteen. At eighteen the supports and treatment were omitted. Her general health was good, but the unsteadiness of gait continued, and as she developed into a young woman increased. She was placed under the care of a leading physician six years ago, kept perfectly recumbent fourteen months, and treated with steel without benefit. She came under Dr. Carpenter's care in 1863.

The condition of the younger sister, E. H., æt. twenty-six, is very similar, but the symptoms are not so advanced, neither is she so helpless as her sister was three years ago; she has followed similar plans. The irregular gait was observed when she was fourteen. She is now well developed, with a healthy rosy face. When she speaks it is with hesitation, and as if she had something in her mouth. She is able to thread her needle, but could not touch the tip of her nose if her eyes were shut. She walks more nervously than her sister, and her progression is more sudden, amounting to a half run. Dr. Carpenter summed up the points upon which he asked the opinion of the Fellows under four heads, viz.: (1) The cause for the development of the disease; (2) its nature; (3) its pathology; (4) its treatment. He referred the first point to some hereditary defect in nutrition of nerve matter. That the curvatures were coincident in point of time with development of disease as effects of a common cause, viz., degeneration of nerve matter—that they were not cases of locomotor ataxy at present. He combatted the opinion of the translator of Trousseau's "Clinical Medicine" that the pathognomic sign of locomotor ataxy "was the peculiar deficiency in the power of co-ordinating voluntary movements," basing his objection on the absence of pain, of urinary disturbance or ocular complication, as well as the fact implied by their youth and sex. The want of co-ordinating power being the most prominent symptom. He considered that in these cases the mischief was limited to the cord, and that there was no cerebellar complication, this idea being supported by the absence of subjective symptoms of brain disturbance and the superior intellectual power. He referred to the experiments of Linget and Bernard, which prove that when the posterior roots of the spinal marrow are divided there is less co-ordinatory power, and that the harmony of movement is interfered with, and that Dr. Lockhart Clarke had distinctly made out that the posterior roots of the spinal cord were diseased in locomotor ataxy. The author concluded that in these cases where the posterior columns were diseased the irritability of the muscles was found to be depressed, whilst their sensitiveness to pain was increased, that electric currents excited violent pains. This was not the case with these patients, moderate galvanic currents were not

distressing. The author also pointed out a typical case of locomotor ataxy, pointing out the different manner of progression as compared with the gait of these young ladies.

A discussion then took place, in which DR. LOCKHART CLARKE and DR. RICHARDSON joined, at the conclusion of which

THE PRESIDENT proposed that a committee be formed to examine these cases and report to the society at the next meeting. He named Drs. Richardson, Hughlings Jackson, and Carpenter, and requested the assistance of Dr. Lockhart Clarke.

The discussion was then adjourned, the PRESIDENT thanking Dr. Carpenter for his interesting communication, and also the young ladies, for the opportunity they had afforded the society of seeing them.

---

### THE PATHOLOGICAL SOCIETY OF DUBLIN.

WE understand that a very animated discussion took place, on Saturday last, at the meeting of this Society, in reference to propositions laid before it by two of its members. It was suggested by one gentleman that the meeting should take place in the evening instead of at four o'clock in the afternoon, and that the communications made to the Society should be the subject of debate. In the course of the discussion, another member animadverted upon the constitution of the Council, which he considered was of an exclusive and not by any means a representative character. He complained that certain of the clinical hospitals of Dublin were without any delegate in the administration of the Society, while other hospitals enjoyed an undue share in its management.

We do not enter more fully into the subject matter of these complaints, inasmuch as our knowledge of the facts is unofficial, but we are strongly impressed with the consideration that the suggestions offered by these members are fully justified by the system of management and government of the Society.

Hitherto, its Council has been a sort of "Holy of Holies," into which no member, however energetic or talented, could hope to penetrate, except by the kind condescension of the Levites on guard. The Society itself is, in all respects, an

abnormity, numbering amongst its members some of the best-named men in the Irish ranks of the Profession, and including in its proceedings an embarrassing overflow of interesting communications. Its meetings have, nevertheless, been from year to year held in *Camera*, at an unholy hour of the day, and without public notice. The theatre in which the meeting is held being crowded with students, who actually used to take their attendance on the Society as a course of practice of medicine, and promulgated their certificate as they would the *testimonium* of a regular course of lectures, the members are obliged to content themselves with standing room against the wall, or a seat on somebody's knee, and the entire hour of meeting is enlivened by the constant pushing, crushing and shuffling of unpunctual members coming in, or gentlemen, who have "shown" themselves, going out. Beset with such difficulties and distractions, some surgeon presents a valuable and interesting pathological specimen, which, to do it and its contributor justice, would deserve three-quarters-of-an-hour examination and discussion. Yet, the moment the bow of the contributor has been made to the President, the specimen is precipitately carried away, and another gentleman "takes the floor;" and while under similar *desagremens*, he attempts the hopeless task of driving the views of his predecessor out of the heads of his hearers, usually succeeds in producing a sense of pathological bewilderment to the audience.

But the proceedings of the Society are not allowed the attentive criticism they deserve, even when they come to be perused. From the moment when the words drop from the mouth of their author, as much care is adopted to put them out of sight and mind as if they were diplomatic telegrams.

Three months after they have ceased to be of any interest, they are carefully and honourably interred on the bookshelves of a few hundred medical literati, while nine-tenths of the medical world even in Ireland are hardly aware that the Dublin Pathological Society exists as an organisation, not for the diffusion of useful knowledge, but rather for the embalment and sepulture of medical science, and the discouragement of over-eager students in the investigation of disease.

#### THE CONJOINT EXAMINATION BOARD FOR IRELAND.

It will be recollected that at its last meeting the General Medical Council adopted a resolution recommending the formation of a Central Examination Board in each division of the Kingdom of the Corporation of all the medical authorities in each.

This proposition was, as far as Ireland was concerned, pooh-poohed by Sir Dominic Corrigan, who declared that it never would be carried into effect in Ireland, and broadly insinuated that he would prevent it. The Council resolved thereupon to give the Licensing Bodies until the 1st of January to consider the question, and frame their arrangements, and declared that if they failed to do so by that time, they would call upon the Government to do so.

Nearly seven months have passed and no movement is visible in the "Irish medical authorities." We understand, indeed, that the Council of the Royal College of Surgeons have some weeks since invited the University of Dublin, Queen's University, College of Physicians, and Apothecaries' Company, to a conference of delegates to discuss the sub-

ject, and that each of these bodies has expressed its desire for such a meeting, except the College of Physicians. It is further said that a certain party in that College is anxious to impede the negotiations, and objects to meet the Apothecaries' Company as parties to the arrangement.

Thus we have arrived within a month of the date fixed by the Medical Council, and nothing has been done. We profess ourselves quite unable to comprehend a policy of obstruction on the part of any licensing body. Two successive years of Parliamentary threatening, and the expressed intentions of Mr. Forster, on the part of the Government, have left no room for doubt as to what we may expect in the coming Session. We have room to anticipate nothing but the unsparing pruning of medical corporations, if, indeed, the Government will content itself with so mild a measure, and it is equally probable that the road to medical reform will be cleared by the total annihilation of the Licensing Bodies. The College of Physicians of Ireland must know this as well as we do, and they should not place dependence on the chances which ministerial embarrassments gave them last year. Mr. Forster has, we think, given every latitude which could be expected or desired, and if the medical corporations will not take the hint, and put their houses in order, it would be unjust to the Profession to deal tenderly with their obstinacy and obstructiveness.

#### MEDICAL ASPECT OF THE FRANCO-GERMAN WAR.—No. IV.

*The Soldiers.*—There is in the reports by correspondents and others capable of forming an opinion on the subject, sufficient to indicate that a very great difference existed in the *physique* as well as the *morale* of the troops constituting the opposing armies, differences which beyond doubt had an important bearing upon the result of the campaign, and which may appropriately be referred to in the present *résumé*.

*French.*—In ordinary times about 325,000 young men having attained the age of twenty-one years became subject to military service, but of these 61,000 are exempted on account of various reasons, deficient height being the most general; others were exempted by the operation of that unlucky rule which permitted conscripts to purchase immunity from personal service, the result being that the social tone of those unable similarly to obtain exemption, became lowered. Unfortunately also it is beyond doubt that a degree of laxity and want of discipline in small matters had for some years been in operation, and it is somewhat broadly asserted that when the time of real trial came it was not alone in small matters that this condition existed. But besides the ordinary annual contingent, large numbers of men had, in 1870, to be enrolled, and this was effected partly by conscription and partly by voluntary engagement. Of the men so raised some entered the regiments of the regular army, others the various corps of National Guards then brought into existence. Many of the older soldiers were, as we have just seen, deficient in discipline; those suddenly armed in a great emergency had not had time to acquire the tone and character of soldiers, and here are some of the consequences which followed: "That many of the troops, both of the line and contingents were sent to face the enemy while as yet imperfectly drilled is only too notorious, but the natural degree of their military ineffi-

ciency is perhaps not generally known. For example, we read of some *mobiles* in the provinces, being so very insufficiently drilled that in throwing themselves upon the ground they wounded each other with the bayonet, and that in getting up again they repeated the clumsiness.\* We moreover learn that there were in the ranks many men who were physically unequal to the hardships of actual service, many were as yet immature lads who had not attained manhood, also that after the experience of the war against the Prussians and that against the Communists, *M. Thiers* expressed himself in regard to young soldiers much as the first Napoleon and many others had done before him. *M. Thiers* "believes in old soldiers. He will not hear of young men simply drilled for a number of months and returning to their villages every year."† With all these serious drawbacks the individual courage and *pluck* of the men is testified to. What is to be learnt from the observations made is, that individual bravery was of itself of little count against such serious defects as we have seen to pervade the masses.

*German.*—The soldiers in the German armies were selected from among men of twenty years and upwards, those of the *Landwehr* averaged from twenty-eight to thirty-two years of age, many of them being married and having families. They were all powerful men in the prime of life, well educated, with "a sense of responsibility which the French want. Splendid marchers, strong, self-restrained, self-respecting, earnest, manly fellows."‡ We had almost thought we were writing of Cromwell's Ironsides; and like them the Germans are said by eye-witnesses to have "fought like devils." And they marched as well as they fought. When pursuing their defeated enemy they kept up with horses and carriages, at a *swinging* pace, and in full campaign order. They had one great advantage over their opponents in that they carried no tents, although we learn that the health of the men at times did suffer in some degree when they had to bivouac during inclement weather. While actively engaged they are sober, able to march thirty miles a day for three successive days *without a case of sunstroke* occurring among them, a circumstance in somewhat striking contrast to what is said to happen when one of our British regiments is called upon to proceed a few miles during a summer day. With all this the strictest discipline was maintained among the German troops. Even on the march men were reprimanded "if their buttons were not polished, and their cuffs turned down," and no sooner did they occupy a place than the soldiers were busy brushing and beating their clothes." It is manifest that the several characteristics here briefly alluded to while they have an all important bearing upon the efficiency of armies in a military sense, have also a direct bearing upon points affecting the health of their several component parts, and that this being the case they possess an especial interest, more especially at the present time for all who are concerned in the reorganisation of our forces.

*The Cavalry Seat.*—There are probably few of our readers who have not at some time or other observed with mingled pain and amusement the British dragoon on horseback, his charger at full trot, and he himself bumping up and down in his stirrups as if the great object of his being were to produce in his own individual self one or other or both those maladies formerly enumerated in military

medical nomenclature as *hernia inguinalis* and *hernia humoralis*. A similar "seat" was at the beginning of the late war in use by the German cavalry, and perhaps is so again now that piping times of peace have returned; that it was abandoned in actual service and why it was so we learn however from the correspondent of the *Daily News*,\* himself an ex-dragoon. He tells us that early in the war "the German cavalry have almost without exception betaken themselves to the practice of 'jockeying' on the trot." The German officers and men alike assert that experience has convinced them that to jockey on the trot is easier for the horse, spares his back more, averts his tiring, while beyond doubt, it is pleasanter for the horseman in a long journey. Mr. Forbes further says in illustration of his remarks that Lord Cardigan, who was a very strong opponent of "jockeying" had more sore backs among the horses of his hussars than any other regiment in the service, and adds, "I believe that the legitimation of *jockeying* would keep the dragoon longer sound." So do we, and so if we mistake not do the surgeons of most of our cavalry regiments.

*Drunkness.*—What do we find on this unpleasant subject as it affected the *Celtic* and *Teutonic* soldiers during the late events in France? Is this vice the great prerogative of the free born and independent Briton, or has he rivals in its pursuit? Alas! he is by no means singular in his taste for intoxicating drinks. Of the French soldier and *mobile* we read that in the cold days of winter *vin ordinaire* was deemed by no means "comforting," and that spirits in very considerable quantities not unfrequently took its place with the following among other results, namely, that the Academy of Medicine discussed the question how far the indulgence which prevailed in Paris during the siege was a cause of the unfortunate termination which so often happened in the cases of the wounded, an insuccess said by *M. Verneuil* to be often induced by *alcoholism*. Also that a *Société patriotique de tempérance* was set on foot of which "Le but est de combattre efficacement *Pyrogerie*."

But it was not alone the French who are said to have indulged in drunkness. The Germans, whose sobriety during the time of fighting, seems to have been remarkable, gave themselves up to indulgence during the time they besieged Paris. As one reason of this it is said that being deprived of the beer which appears to be an indispensable article to them, they the more readily indulged in such spirits as they were able to possess themselves of. We come across several instances of this in published correspondence, and perhaps it may be consolatory to know that when soldiers of other nations have the chance of indulging in strong drink, their performances in this respect are by no means far behind those of our own much respected Private Thomas Atkins.

## Notes on Current Topics.

### Scotch Weather.

A TEN years' average of the mean temperature in Scotland shows that July is the warmest month, August the next, but during the past quarter August was 1° 2 warmer than July, and the warmth was felt the more that the air was nearly still, and what little breeze there was

\* *Daily News Correspondence.* P. 411.

† *Observer*, 1st October, 1871.

‡ "My Experiences." Vol. I. Pp. 253, 18, 220, 267.

\* "My Experiences." Vol. II. P. 180.

came from the south-west. This higher temperature during August had its effect on the mortality. In ordinary years, when July is the warmest month and August the next, the mortality gradually decreases from May to September. But during the past quarter, the mortality of August exceeded that of July. As the heat was not great, however, the mortality continued comparatively low; so that the August deaths over Scotland only exceeded those of July by 80, instead of being 190 below them. July might be characterised as a rainy month, with a full mean temperature, but rendered cold to the feeling, and backward to the crops, in consequence of the unusual prevalence of cloud, from which rain was continually distilling, and a want of sunshine. August, again, was a warm month, with a clear sky, much sunshine, and little rain. While September was a cold month, with an unusual prevalence of easterly and northerly winds, and a consequent deficiency of rain. The *Quarterly Report* shows that the mean barometric pressure, reduced to the sea-level and to 32° Fahr., was 29.692 inches in July, 29.908 inches in August, and 29.930 inches in September. The mean temperature of the quarter was 56°·3, being 0°·6 higher than that of the ten previous years. The mean temperature was 57°·7 in July, 58°·9 in August, and 52°·2 in September. The absolute highest temperature was 79°·2 in July, 86° in August, and 78° in September. The absolute lowest temperature in the protected thermometer was 34°·7 in July, 35° in August, and 24° in September.

#### What to do with Leeches that have been used.

A CORRESPONDENT of the *Boston Medical and Surgical Journal* asks what shall be done with leeches which have once performed their duty. To a physician in the country, replies the editor, such a query is of more importance than to a physician in the city; the former is often obliged to use a second hand article, while the latter orders fresh. The only method of relieving the leech of blood is of course to induce him to disgorge it, or allow him to digest it. Many practitioners "strip" the leech, or else cause them to disgorge by means of salt. Such treatment if it does not cause their speedy death, generally renders them unfit for a second application. Both methods are barbarous. We think by far the preferable method is that employed by our correspondent, we give his words:

"My mode of treatment is the following: I never 'strip' them or cause them to vomit. I let them enjoy their fill of human gore, keeping them in cold spring water, which is changed regularly every day. In a few weeks' time their meal is all digested and they are ready for a fresh application. I have never known them to die when treated in this way. What is the experience of others?"

#### The Statistical Society.

At the first meeting of the Statistical Society for the present session last week, an address was delivered by Dr. Wm. Farr, who asked the public to make fresh efforts to extend the science which this society was founded to promote. He expressed himself as looking forward to the foundation at the universities of Professorships of Statistical Science, which had paramount claims to every encouragement both in honours and rewards. Political economy is now taught in the Universities as a subsidiary study; and though it has a field of its own, part of

it forms legitimately a small part of statistics, and the two sciences are closely connected. Dr. Farr also gave many interesting particulars of Mr. Babbage who attended the meetings assiduously at the origin of the society, and who was so well known by his two great and long-sustained efforts to construct calculating-machines—to produce by mechanism what had, up to his time, been either impossible, or the unaided work of human brains. Dr. Farr thought we ought to have buildings for scientific societies, and then said "This Society especially has the strongest possible claims upon her Majesty's Government, for it is interposed as a critical independent body between Parliament and the Government departments; the papers in the Society's *Journal*, full of sifted facts, throwing the clearest and most impartial light on the political questions of the day under discussion, are to the country of incalculable pecuniary value. As proof, take the whole series of thirty-four volumes, and as samples the last numbers. This society is an arena where members can meet ingenious men—men not in Parliament—with strong convictions, who can not only expound but discuss their views before a scientific audience; but it is evident that such discussions demand for their full development a small convenient theatre."

#### Emigration.

In reference to increase of population, emigration is of importance. From the chief ports at which emigration officers are stationed, it was ascertained that 71,400 persons emigrated from Great Britain during the quarter, of whom 32,312 were English, 16,139 Irish, 14,587 foreigners, and 5,862 Scotch, while of 2,500 the place of birth was not ascertained. Allowing 212 as the Scotch proportion of those whose origin was not ascertained, the total Scottish emigrants during the quarter would amount to 6,074, which, deducted from the excess of births over deaths, would leave 5,780 persons as the increase of the population during that period.

#### Prevalent Disease of Scotland.

AMONG the other important points discussed by the Scottish Registrar-General is that of the prevalence of several diseases. As the eight principal towns of Scotland furnish the particulars of the ages and diseases which proved fatal, as their united populations amount to nearly a third of that of Scotland, and as these towns are well scattered over the country, the diseases which prevail in them serve to give a very fair idea of those which are affecting the people generally. It appears that the deaths in the eight chief Scotch towns would number 2,438 in July, 2,450 in August, and 2,226 in September. Contrary to the usual average, August proved more fatal to the population than July. In this respect 1871 agreed with 1868. During August there was an increase among those diseases which are reckoned to belong to the zymotic class; and, on looking at the mortality of the individual diseases in that class, it is seen that, while almost all other diseases had decreased in fatality during that month, the deaths from diarrhoea had largely increased—viz., from 78 in July, to 188 in August. August, says the Registrar, was our warmest month—indeed, the only month of the year when there was any amount of warmth at all—and the warm weather invariably increases the bowel complaints. As these diseases are not rapidly fatal, many of

the deaths from these diseases, therefore, did not occur till September, so that 147 deaths from diarrhoea were registered during that month. The epidemic constitution, which gives rise to or encourages the spread of small-pox, appears to be very strong this year, and would seem to be on the increase; for, while only 24 deaths from that disease occurred in the eight towns during July, 30 occurred in August, and 47 in September. Measles, on the other hand, was rapidly abating; for, while 254 deaths therefrom occurred in July, only 124 were in August, and 65 in September. Scarletina, as almost always happens, increased just in proportion as measles abated; for the deaths were 42 in July, 63 in August, but 107 in September. The deaths from diphtheria very slightly diminished, being 30 in July, 29 in August, and 27 in September, or, allowing for equal days, diminished only one day a month. It is worthy of remark that in the towns diphtheria has been proportionally more common among the middle and upper classes than among the lower classes. Hooping-cough showed a slight tendency to increase during September; for the deaths, which were 43 in July, and 44 in August, increased to 62 in September. Croup showed a still greater tendency to increase with the progress of the year; for 15 deaths occurred in July, 29 in August, and 32 in September. The bowel complaints—diarrhoea, dysentery, and cholera—caused 97 deaths in July, 213 in August, and 165 in September. Fever abated considerably during August and September; for, while 102 deaths therefrom occurred in July, only 83 happened in August, and 80 in September. The diminution, however, was far greater in typhus fever; for 45 deaths occurred in July, but only 38 in August, and 28 in September. Enteric fever, however, was nearly as fatal in September as in July—July registering 33 deaths, and September 31, though there was a diminution during July to 23 deaths. Erysipelas increased during August and September. The deaths from consumption, as usual, diminished with the advance of the season, 334 deaths occurring in July, 285 in August, and 259 in September. Apoplexy and paralysis were most fatal during the warm month of August, and caused 76 deaths in July, 99 in August, and 71 in September. Diseases of the heart were much more fatal during the warm month of August; for July furnished 81 deaths, September 63, but August 117. Diseases of the respiratory organs abated during the genial month of August; for while 340 deaths occurred in July, and 326 in September, only 291 happened in August. Inflammatory affections of the digestive organs were most common in August; for, while 196 deaths therefrom occurred in July, and 169 in September, 227 were in August. Kidney disease greatly abated during the warm month of August, and rose again with the colder weather of September.

### Physiography.

THE lectures on the "Elements of Physical Science," intended for the instruction of women, were commenced by Professor Duncan, who took the term physiography, intending thereby the science of natural objects. That the term really misled the ignorant was seen by the amusing mistake mentioned by the lecturer of some one asking him if he meant to lecture about faces. The lectures were illustrated by maps and drawings, and are very popular. Professor Duncan said that the first thing to notice in connection with physiography is that the surface of the earth is constantly undergoing more or less appreciable changes; so that, during long ages of time, the landscape of every part of the world alters materially. The land wears away, and the results of its disintegration by heat, cold, wind, rain, and ice are carried down to the sea floor. This wearing away is called denudation by physiographers. Denudation, and the removal of the results of it, contribute largely to the formation of the contour of the ground. A

simple, but a very good lesson in physiography might be gained by looking into the operations of their own river Thames. He would take them back to the period when the rhinoceros, the elephant, wild cat, and other great animals, were to be found in England, and when the ancient Britons had to content themselves with weapons and implements of warfare, and ask them to endeavour to realise the amount of mud and stone which has been swept down to the sea by the action of the river Thames. It has been calculated that 140,000,000 cubic feet of mud passes down the Thames every year. As a mass of stone this amount of mud would represent 520 tons in weight. Multiply this by 4,000 or 5,000 and a pretty considerable amount of material would be found. All this mass of earth and stone had been detached from the surface of the earth. The changes which this must have made in the appearance of the valley of the Thames may be easily imagined. This amount of soil represents roughly the annual wear and tear of the valley in which the Thames runs. A river running two miles an hour is capable of carrying along with it a pebble two ounces in weight, and one running at the rate of ten miles could carry a stone weighing ten tons. The Thames at London Bridge is a mass of fresh water one-sixth of a mile wide; its depth in some places thirty feet, and in others only twelve feet. Its water runs down towards the sea for about seven hours, and then runs up towards Teddington weir for about five hours twice in the day. About 115,000,000 cubic feet more water moves down than passes up beneath London Bridge every day. Above Teddington the water always runs downwards towards London Bridge in a continuous stream from Thames Head, in Wiltshire, which is 170 miles from London and 370 feet above the water of that bridge. The course of the Thames and its affluents is determined by the shape or contour of the ground of the Thames basin. This is bounded and separated from other river basins by the high ground which forms the Chiltern Hills, the Cotswolds, and the north downs. Denudation has formed the valleys, and their shape determines the course of the main river and its tributary streams. The basin of the Thames receives every year water on its surface, in the shape of hail, rain, snow, or dew, to the bulk of 2½ cubic miles. These result from the condensation of the watery vapour of the atmosphere which arises from all watery bodies owing to the heat of the sun. Only a portion of the water which falls on the Thames basin reaches the sea by way of the river, for much is evaporated, and much sinks deep into the ground. The water of the Thames is constantly circulating, and the agent of the circulation is the sun. Rain, rivers, and the formation of valleys and the changes in the landscape are natural phenomena, which are influenced by the laws that regulate the heat of the sun. The area of the Thames basin was little more than 6,000 square miles, and about 24½ inches of rain fall into it every year. To mass all this water together would make 2½ cubic miles of water.

### Work.

THE medical profession has the opportunity of judging of the effects of work on the human system, and some of our brethren fall victims to excessive mental or bodily toil. It is of the greatest importance that this subject should be more commonly studied, for it ramifies in every direction both preservative and curative medicine. The influence of work on health was the subject of the celebrated Bouchardat's two lectures before the Paris Faculty of Medicine as long ago as 1862, and no one has more beautifully illustrated it than this able professor of hygiene. In commencing his course, which was afterwards printed, he observed that one of the forefathers of philosophy—Plato—said that our body is impaired by rest and inaction, and preserved chiefly by exercise and motion. Rest will do harm to the mind as well as to the body. I pur-

pose to demonstrate the truth of these principles. I hope I shall prove to you that man is preserved and rises by the harmonious exercise of both body and mind, and that inaction impairs him physically as well as morally. I think I am true to the purpose of the useful works of the Polytechnic Association, in trying and asserting by arguments borrowed from the most largely understood of health, that physical and intellectual labour is a necessity of human organisation—a condition of health, of morality, and indefinite improvements. That is a question of general interest, which will bring us to inquire into the most efficacious means of contending with our most implacable enemies—spleen, misery, old age, and premature death; of preserving as long as possible the attributes of youth; and, last of all, keeping away the fatal hour to the utmost limit. To hit the aim I have just pointed out, it must be thought of for a long time, as it is easier to keep up a building in a good condition than to raise up again a ruin. In order to combine harmoniously intellectual and bodily exercise for many constitutions and social situations, it requires daily efforts and two difficult things—time and a strong and determined will; in short, what is still more difficult, and yet necessary, will be to subdue our mischievous propensities. But I shall be easily understood when speaking to an audience well prepared by the practice of the truths I am just trying to unfold. This is the plan I intend to follow in both lectures. I shall study first the physical, physiological, and healthy effects of bodily and intellectual labour. I shall say afterwards what are its advantages and inconveniences, according to climates, sex, and ages. Then I shall end by the study of labour's influence on the fate of nations."

### The Iodides.

In his paper on "Ozæna," at the Medical Society of London, Dr. Prosser James drew attention to the value of other iodides than that of potassium, particularly to the iodides of sodium and calcium, which, though used abroad, have not been much employed in this country. The author exhibited specimens of those salts which had been prepared for him by Mr. C. R. C. Tiehborne, of whose accomplishments he spoke in high terms. It appears that the iodide of sodium is far less unpalatable and quite as efficacious as the iodide of potassium. The iodide of calcium was spoken of as not at all nauseous, in fact, as a good substitute for table salt; while its mild action rendered it particularly suitable for strumous diseases, especially in children.

### The Responsibility of Irish Dispensary Officers.

A VERY important inquiry has been recently held by the Poor-law Commissioners, and their decision thereupon was given last week.

Dr. Hannifin, of Milltown, Kerry, had been called upon to attend a woman named Quirk, in her confinement. Having done all that was possible to assist natural labour, he found that the urgency of the case would oblige him to deliver with the forceps. Just as he was about to operate, the priest of the parish came in, and Dr. Hannifin very properly retired, in order that the patient might have the consolation of her church. On his return after the departure of the priest, he discovered that that gentleman had decided that the woman should "make her way through the night" and the relatives accordingly refused to permit

Dr. Hannifin to do what was proper and necessary under the circumstance. Accordingly having protested that "they would all regret it, because the child would surely die during the night, and the mother's life would be endangered," the next morning he did remove a dead child, and the woman died afterwards, and as a reward for his attention to the case, he was put on his trial for neglecting it.

The Commissioners say that "no evidence was produced to sustain the complaint, and that Dr. Hannifin had been most diligent and attentive in his attendance," and they further observe, while "they have no authority with regard to the reverend gentleman's proceedings," they consider his interference was to be regretted.

### The Royal Institution.

THE following lecture arrangements at the Royal Institution for 1871-72 are announced:—

Prof. Tyndall, LL.D., F.R.S.—Six Christmas lectures (adapted to a juvenile auditory) "On Ice, Water, Vapour and Air," on December 28, 30, 1871; January 2, 4, 6, 9, 1872.

Dr. W. Rutherford, F.R.S.E.—Ten lectures "On the Nervous and Circulatory Systems," on Tuesdays, January 16 to March 19.

Prof. Odling, F.R.S.—Ten lectures "On the Chemistry of Alkalies and Alkali Manufacture," on Thursdays, January 18 to March 21.

W. G. Clark, M.A., Vice-Master of Trinity College, Cambridge, late Public Orator.—Six lectures "On the History of Dramatic Literature, Ancient and Modern," on Saturdays, January 20 to February 24.

Moneure D. Conway, Esq.—Four lectures, "On Demonology," on Saturdays, March 2 to 23.

Dr. W. A. Guy, F.R.S.—Three lectures "On Statistics, Social Science, and Political Economy," on Tuesdays, April 9, 16 and 23.

Ed. B. Tylor, Esq., F.R.S.—Six lectures "On the Development of Belief and Custom amongst the Lower Races of Mankind," on Tuesdays, April 30 to June 4.

Prof. Tyndall, LL.D., F.R.S.—Nine lectures, on Thursdays, April 11 to June 6.

R. A. Proctor, Esq., B.A., F.R.A.S.—Five lectures "On Star Depths," on Saturdays, April 13 to May 11.

Prof. Roscoe, F.R.S.—Four lectures "On the Chemical Action of Light," on Saturdays, May 18 to June 8.

The Friday evening Meetings will commence on January 13.

The Friday evening Discourses before Easter will probably be given by Mr. W. R. Grove, Q.C., the Archbishop of Westminster, Professors Odling and Humphry, Dr. Gladstone, Messrs. C. W. Siemens, R. Liebrich, John Evans, and Prof. Tyndall.

### The Dublin Class of Students.

SATURDAY last was the latest day for entry of students in the Dublin Medical Schools. The numbers entered for dissections were, we believe, as follows:—

|                                |     |
|--------------------------------|-----|
| School of Physic.....          | 195 |
| Royal College of Surgeons..... | 153 |
| Ledwich School.....            | 191 |
| Carmichael School.....         | 94  |
| Stevens' Hospital School.....  | 85  |
| Catholic University.....       | 71  |

### Ozæna.

An interesting discussion on "Ozæna" took place on the 20th inst., at the Medical Society of London. It was introduced by Dr. Prosser James, who took a more hopeful view of the complaint than that entertained by the majority of writers. He described the several varieties, catarrhal, strumous, syphilitic, accidental, &c., and their

appearances in the rhinoscopic mirror. The treatment, both general and local was also detailed. Locally, one of the permanganates applied in various ways, seemed to be the most effectual treatment, and though various astringents were mentioned by Fellows, who joined in the discussion, the general impression seemed to be that the permanganates were the most trustworthy applications.

### Medical Society of the College of Physicians, Ireland.

A MEETING will be held in the College hall on the 29th November. The following communications will be read: 1. Dr. Eames "On the Use of Phosphorus in Diseases of the Skin." 2. Dr. Hawtry Benson "On Elephantiasis Græcorum." The individual affected with the disease will be presented before the Society.

### St. Andrew's Medical Graduates Association.

THE fifth anniversary session of the Association will be held at the Freemason's tavern, Great Queen street, on Friday and Saturday next.

The session will begin on the 1st, at 7 p.m., when the Report of the Council will be read, and new officers elected, after which Dr. Swete will open a discussion on "Habitual Drunkenness, and its Treatment, Medical and Legislative."

On Saturday, the 2nd, at 5 p.m., the President, Dr. Day, of Stafford, will deliver the anniversary address: "The Historical Steps of Modern Medicine."

The anniversary dinner will take place in the evening, at 6 p.m.

### Indian Medical Service.

NOTICE has been given that an examination of candidates for at least forty appointments as assistant-surgeons, will be held in London in February, 1872. The application of candidates for examination will not be registered after 7th January, 1872.

### Pharmaceutical Society.—Notices.

THE next meeting of the Pharmaceutical Society will be held on December 6th, at eight o'clock. The following papers will be read:—"The Substitution of Proportional Numbers for Specified Weights and Measures in the Description of Processes in the Pharmacopœia," by Prof. Redwood. "Method for the Estimation of Morphia in Opium," by Mr. John T. Miller. "The Syrup and Resin of Tolu, Tincture of Cinnamon," &c., by Mr. A. F. Haselden, F.L.S.

### Army Medical Department.

THERE will shortly be some promotion in this department, consequent on Dr. Jones, C.B., succeeding to his Inspectorship, and the retirement on half-pay of Deputy Inspector-General J. Summers, M.D., G. C. Meikleham, M.D., and Surgeon-Major Buckle, M.D.

THE will of Sir Roderick Impy Murchison, F.R.S., has just been proved by his executors, under the personality of £250,000. He has bequeathed funds to the University of Edinburgh, to endow a Chair of Geology, and has left his physician, Dr. Bence Jones, £1,000.

### Unqualified Practitioners.

AT an inquest held in London on Saturday, upon the body of a child that died whilst under the treatment of a chemist, Mr. Richards, M.R.C.S., said he was called by the mother of the child, when it was too late for him to render assistance. The mother believed the apothecary who had medical charge of the child was a "doctor," and he never deceived her. The Coroner stated that from the medical evidence there could be no question that this was another life added to the category, which had been sacrificed for want of proper medical assistance, poor people blindly believing that every chemist, or self-styled doctor is a qualified medical practitioner, and, as in this case, the party concerned had not the honesty to undeceive the parents. There was no reason why the life of this child should not have been saved. With this belief we are sorry the Coroner did not commit the said chemist for manslaughter.

DR. RICHARDSON'S next lecture on experimental and practical medicine will be on "The Synthesis of Pulmonary Congestion and Hæmorrhage."

AN epidemic of small-pox has also broken out in Birmingham, and as the contagious wards of the Queen's Hospital are full, steps are being taken for the erection or conversion of a temporary hospital.

THERE are about forty appointments vacant in H.M. Indian Medical Service. For these, examinations will be held in London in February, 1872. Particulars will be found in our advertisement columns.

HER MAJESTY, the Queen, has arrived at Windsor from Scotland. Though weak from her late severe illness, her medical attendants state that she bore the fatigue of the journey very well.

IN the metropolis the last weekly return gives 1,626 deaths, being 59 below the average of the corresponding week for the ten preceding years. Seventy-six persons died from small-pox; from bronchitis, 287, as against 179, 190, and 180 in the three weeks preceding.

IT is reported that the jury in the Kelly trial have brought an action for libel against the proprietors of the *Times*. Perhaps Mr. Butt, Q.C., will oblige us with the same luxury. We made some rather severe comments upon the case.

OWING to the great prevalence of small-pox in Sheffield two hospitals are about to be erected for the accommodation of the patients. Upwards of 400 cases are reported by the relieving officers alone, and these are independent of those under private treatment.

IT is announced that the Brown Institution, under the government of the University of London, for studying, and, without charge beyond immediate expenses, endeavouring to cure the maladies and injuries of quadrupeds and birds useful to man, will be opened on the 1st of December, 1871. It is situated in Wandsworth road, Vauxhall. The cost of maintenance of each animal received into the institution must be defrayed by the owner.

In a paper appended by the Admiralty to the annual report on the "Health of the Navy," Staff-Surgeon Wade relates many interesting facts respecting the system of training boys for the navy, which was introduced eight years ago. The five training ships offer accommodation for 3,000 boys, and 2,884 appeared to have entered the service last year. The boys from the western counties, with some previous knowledge of maritime life, generally turn out well; but those from the midland and northern counties are "utterly ignorant of sea-life." London, though having an unlimited supply, turns out a rather indifferent stamp; Ireland has sent a large number to sea since a recruiting station was established at Belfast; whilst Scotland is complimented for the "intelligent, well-behaved lads" whom it contributes to the navy. "The highest in the social scale," among the boys in the training ships, according to Surgeon Wade, "were the so-called clerks in offices, though upon inquiry there had been but slight claim to the appellation; they were generally labouring lads of better education than their fellows, who had been employed writing. I only met with two who had been clerks from the time they left school. Greenwich School, often taken to be a nursery for the Royal Navy, sends very few boys, and these generally weak, and below the standard." "Dividing the occupation of the boys previous to entry into outdoor and indoor, which is perhaps the best practical division, there can be no doubt but that those who have followed the former are to be preferred as better adapted to the life on board ship."

## SCOTLAND.

### THE REGISTRAR-GENERAL'S QUARTERLY RETURN FOR SCOTLAND.

THE quarterly return of the births, deaths, and marriages registered in the divisions, counties, and districts of Scotland for the quarter ending 30th September, 1871, has just been issued. During the quarter ending 30th September, 1871, there were registered in Scotland, 28,689 births, 16,835 deaths, and 5,424 marriages; and these numbers indicate that the proportion of births, deaths, and marriages was slightly above the corrected mean of the corresponding quarter of the ten previous years.

**Births.**—28,689 births were registered in Scotland during the third quarter of the year 1871. This indicates an annual proportion of 340 births in every ten thousand persons, or 3·40 per cent. The corrected average of the corresponding quarter during the ten previous years, was 339 births in every ten thousand persons, or 3·39 per cent. The proportions of births has, therefore, been slightly above the mean.

**Deaths.**—16,835 deaths were registered during the quarter ending 30th September, being in the annual proportion of 200 deaths in every ten thousand persons, or 2 per cent. The mean death-rate of the quarter during the ten previous years was 195 deaths in every ten thousand persons, or 1·95 per cent.; so that the death-rate of the past quarter has been above the average. In England, during the same quarter, the deaths not only were above the average of the quarter, but even exceeded the deaths of the previous quarter. Thus, during the September quarter, 121,196 deaths were registered in England; being in the proportion of 213 deaths in every ten thousand persons, or 2·13 per cent. The mean death-rate of England during the quarter of the ten previous years, was 210 deaths in every ten thousand persons, or 2·10 per cent. The English mortality was, therefore, both

above its own average, and high above that of Scotland. The death-rates in the four groups of districts into which Scotland is divided closely corresponded with the birth-rates, being highest where the greatest number of human beings was massed together, and lowest in the sparsely inhabited rural districts. Thus, for every ten thousand persons in each of these groups, there occurred, during the quarter, at the annual rate of 261 deaths in the principal towns, 220 deaths in the large towns, 199 deaths in the small towns, but only 149 deaths in the rural districts. This same influence of density of population may be traced in eight divisions of Scotland. Thus, for every ten thousand persons in each division, there occurred during the quarter in the proportion of 124 deaths in the northern division, with 36 persons to a square mile; 168 deaths in the southern division, with 66 persons to a square mile; 222 deaths in the south-eastern division, with 219 persons to a mile; but 246 deaths in the densely-peopled south-western division, with 441 persons to a square mile. Of the eight principal towns, the mortality during the quarter was lowest in Aberdeen, and highest in Glasgow. Thus, for every thousand persons in each town, there occurred the proportion of 18·6 deaths in Aberdeen, 20·7 in Perth, 23·5 in Leith, 23·7 in Greenock, 24·2 in Edinburgh, 24·4 in Dundee, 26·2 in Paisley, and 30·0 in Glasgow. Of the deaths, 5,694 were registered during July, 5,774 during August, and 5,367 in September, being at the rate of 184 deaths daily during July, 186 deaths daily during August, and 179 daily during September.

**Marriages.**—5,424 marriages were registered in Scotland during the third quarter of 1871, being at the annual rate of 64 marriages in every ten thousand persons. The quarter's average during the ten previous years was 61 marriages in every ten thousand persons; so that the marriages during the quarter have been above the mean.

## Literature.

### HYPERPYREXIA.

WE gave an abstract at the time of Dr. Wilson Fox's remarkable paper on "Hyperpyrexia," and it is with pleasure we find that it is now published\* with many important additions. The little book, to which we invite special attention, is a clinical study of rare value on a subject that urgently demands the thought of all engaged in the effort to cure disease. It is clearly shown by Dr. Wilson Fox's cases that the use of cold water may save the lives of those who, without it, are condemned to death. Anyone who demonstrates that cases hitherto considered hopeless, may be snatched from death by means at our disposal, confers an unspeakable benefit on his fellow creatures, and gives a new impulse to scientific medicine. Now, everyone knows that a certain rise in temperature has been looked upon as one of the phenomena of death in these cases. Yet, after that was reached, by assiduously employing the cold bath after the manner indicated by German authorities, Dr. Wilson Fox has the satisfaction of reporting recoveries. His cases are so instructive that we shall give one as an example—merely premising that charts, pulse tracings, and tables, add to the value of the book, which should be read by everyone.

For extract, we take the first case, which is related in detail, and may be regarded as a good model. It is as follows:

Mrs. Brophy, æt. forty-nine, married, no children, was admitted into University College Hospital on the 5th of June 1871. Had lived badly until twelve months ago. Since then

\* "On the Treatment of Hyperpyrexia, as Illustrated in Acute Rheumatism, by means of the External Application of Cold." By Wilson Fox, M.D., F.R.C.P. London: Macmillan and Co., 1871.

she had been in better circumstances. No direct hereditary tendencies; but one aunt had died from rheumatic fever. No previous diseases, except "inflammation of the liver" fifteen years ago; but she was liable to hysteria and palpitation. Menstruation had ceased for twelve months past. Her present illness—her first attack of rheumatic fever—began on the night of the 27th of May, with pain in the right hand. She had had slight pains in the feet for some days previously, but had not laid up. On the 29th (two days later) she had a rigor, which recurred on several successive days. After this the knees and ankles were affected. She knows of no cause for the illness. Did not perspire before admission, had no cough, and was free from pain in the chest or palpitation.

On admission, on the seventh day after the first rigors, or the ninth day of the disease, the patient looked depressed; had an earthy tint of skin; the tongue was furred and tremulous; the joints of all her extremities were painful, but especially the knees, ankles, hands, and feet. Grazing friction was heard over the heart; the apex was in the fourth interspace, a quarter of an inch outside the nipple, but the area of dulness was not increased. The cardiac region was tender. The first sound was muffled at the apex; but there was no distinct murmur. The patient perspired freely. She was placed on the treatment by the perchloride of iron, introduced by my friend and colleague, Dr. Reynolds, half a drachm of the tincture being given every four hours, and the joints were wrapped in cotton-wool.

On the 9th of June (the thirteenth day of the disease), the patient's state was much the same. She perspired profusely; the tongue was still furred. Friction was abundant over the heart; dulness only to the third cartilage. The joints of the upper extremities were more painful, those of the lower extremities less so.

On the morning of the 10th (fourteenth day of illness), there was little change, and the patient still presented the appearance of an ordinary case of acute rheumatism, with a rather marked degree of weakness. Up to this date the pyrexia, as measured by the temperature, had been of an extremely moderate type. On the 5th, the day of admission, it had reached, in the evening,  $102^{\circ}9'$ ; but though taken regularly on the mornings and evenings, it had only once subsequently (on the evening of June 9th) been even as high as  $101^{\circ}2'$ , and on two occasions the morning temperature was  $99^{\circ}2'$  and  $99^{\circ}6'$ . On the morning of the 10th it was measured, but by some accident not recorded, though found higher than before; I am, however, assured by my excellent clinical clerk, Mr. Benham, who took it, and by my most reliable assistant, Mr. Bindley, who was present at the time, that it did not exceed  $102^{\circ}$  (axilla). The patient's aspect was then that of increased prostration, and she was perspiring freely, but no other change was noticed in her general state. At 3 P.M. on the same day (fourteenth day, five days after admission, and twelve days since the rigor), the temperature was found to have risen to  $105^{\circ}$ , and at 5.30 P.M. it was  $105^{\circ}6'$  (axilla). I was sent for, and reached the hospital at 6 P.M. The temperature in the axilla was then  $106^{\circ}4'$ . It had risen  $4^{\circ}4'$  since 9 A.M., or within nine hours. At this time the patient was entirely free from pain in her joints. She was conscious, but spoke with difficulty, and with an extremely slow articulation; otherwise her manner was natural. She complained only of weakness. The face was a dusky purple, the eyes suffused, and the conjunctiva much injected. A thick mucus had collected in the inner canthi. The tongue was tremulous, as were also the hands. She lay with her eyes closed, sighed deeply from time to time, but roused when spoken to. The pulse was 112, respiration 44 in the minute. The heart's apex was immediately under the nipple, in the fourth interspace. The dulness was at the level of the third left cartilage. There was strong friction at the base; a short, highly-pitched murmur at the left apex. Having in one case of rheumatic fever, when the temperature had risen rapidly from  $101^{\circ}3'$  to  $104^{\circ}4'$ , seen an immediate and rapid fall of four degrees to  $100^{\circ}$  within ten hours, and without any subsequent exacerbation, follow the administration of one scruple of quinine, I also gave this patient a scruple of quinine in powder, suspended in mucilage; and this dose was repeated every half-hour until 8.50 P.M., when the patient had taken in all 120 grains of quinine. The last dose was vomited. From 6 P.M. to 7.35 P.M. the temperature oscillated between  $106^{\circ}6'$  and  $106^{\circ}2'$ . The pulse varied from 103 to 112; the respiration from 38 to 44 in the minute,

At 7.50 P.M. the temperature had risen to  $106^{\circ}9'$ ; pulse, 120, respiration 40 in the minute.

Being at this time obliged to leave the hospital for a short time, I requested my assistant, Mr. Bindley, in case the temperature reached  $107^{\circ}$ , to put the patient into a bath at  $96^{\circ}$ , and to keep her there, proposing to endeavour to effect by this means a gradual reduction of temperature. There was, however, some delay in getting the bath prepared, and in the meantime the temperature rose rapidly, being  $107^{\circ}1'$  at 8.5 P.M.,  $108^{\circ}4'$  at 9.15 P.M., when she became entirely unconscious, and  $109^{\circ}1'$  at 9.50 P.M., when the patient was put into a bath at  $96^{\circ}$ . At this time I returned, and thought the patient in the act of dying. She was absolutely unconscious; the pulse was imperceptible; the face in the highest degree cyanotic; and she was drawing the few last irregular, gasping, stertorous respirations which commonly precede the act of death. At 9.55 P.M. the temperature in the rectum was  $110^{\circ}$ . I had questioned whether to take her out of the bath before death, but finding the temperature still rising I determined to make one vigorous effort at its reduction. Ice was fetched; a large lump was placed on her chest, another on her abdomen; a bag filled with ice was tied down the length of her spine; and while two assistants baled the warmer water out of the bath, two others poured ice-water as rapidly as the pails could be filled over the patient. At 10.10 P.M., or within fifteen minutes, the temperature of the rectum had fallen to  $109^{\circ}1'$ ; in five minutes more (10.15 P.M.) to  $108^{\circ}4'$  (the average temperature of the bath being then  $66^{\circ}$ ); at 10.20 P.M. the temperature in the rectum had fallen to  $107^{\circ}5'$ , and at 10.25 P.M. to  $106^{\circ}2'$ . The pulse now became perceptible (140), and the patient showed some signs of consciousness. Brandy was freely given. At 10.35 P.M., or within half an hour of the time that ice was first applied, the temperature in the rectum had fallen to  $103^{\circ}6'$ , and the patient was taken out of the bath (temperature of bath  $63^{\circ}$ ), and the ice-bag was removed from the spine. At 10.55 P.M. the temperature in the rectum was  $100^{\circ}6'$ . The patient could speak, and had a certain imperfect consciousness. The lividity of the face and the suffusion of the eyes had disappeared, but spasms of rigidity attacked at times the muscles of the lips and of the neck, but not of the limbs. At 11.5 P.M. the rectum temperature was  $99^{\circ}5'$ . As there was some difficulty in swallowing, an enema of brandy was now given. The patient took six ounces of brandy from 10.10 P.M. to 11.10 P.M. At 11.25 P.M. the temperature in the vagina (taken here as an enema was retained in the rectum, the patient being nearly unconscious) was  $97^{\circ}4'$ . The temperature had therefore fallen  $6^{\circ}2'$  within fifty minutes after her removal from the bath, when her temperature was  $103^{\circ}6'$ ; and the total reduction from the time of the first application of the ice was  $12^{\circ}4'$  Fahr. within a period of an hour and a half, during which she had really only been exposed to the influence of the cold for half an hour. At 11.40 P.M., or twenty minutes later, the temperature still remaining at  $97^{\circ}4'$  (vagina), and the patient presenting signs of threatening collapse, with a scarcely perceptible pulse, I thought it desirable to guard against any further fall of temperature. Hot bottles were applied to the feet, and a hot water bag was placed against the back. Within twenty minutes the temperature now rose to  $98^{\circ}23'$  (vagina). The pulse became perceptible (130); respiration, 42.

By 1.15 A.M. on June 11th, or within an hour and 20 minutes, the temperature had risen to  $99^{\circ}4'$ ; the pulse was 113, respiration, 32; she had been partly conscious, and now dozed quietly, though some strabismus was noticed about this time. From 1.15 A.M. to 3.30 A.M. the temperature again slowly rose to  $101^{\circ}8'$ ; consciousness was apparently restored; the patient took brandy freely, and spoke; the pulse was 112; respiration, 40. From 3.30 A.M. to 7.35 P.M. a gradual rise of temperature continued, reaching at 7.35 A.M.  $104^{\circ}5'$ . At 7.40 A.M. she was again put into a bath (temperature  $64^{\circ}$ ). Five minutes after her immersion the temperature in the vagina was  $105^{\circ}$ ; it then began to fall, and in twenty minutes had fallen in the vagina to  $103^{\circ}9'$ . She was immediately removed from the bath (temperature of bath at patient's removal  $66^{\circ}$ ); but the fall continued for forty minutes longer, reaching  $99^{\circ}4'$  at 8.40 A.M., or within an hour of this second application of cold there had been a reduction of temperature of  $5^{\circ}6'$  Fahr. At 8.30 A.M., while the temperature was  $100^{\circ}8'$ , there was a strong rigor, which was several times repeated. Hot bottles were again applied, but in spite of these the fall of temperature

\* Subsequently it was found that the patient remembered nothing of the treatment after the first dose of quinine. Some days later she asked if she had not been very ill.

lasted for ten minutes longer—*i.e.*, until 8.40 A.M.,—and amounted to 1.4° within this short time, reaching 99.4°. Deafness from the quinine taken the afternoon before became very distinct about this time, and lasted for forty-eight hours. During the night the patient had, by mouth or enema, about twenty ounces of brandy. The temperature after this rose gradually to 100°, but did not rise above 102° for thirty-six hours. During this period the pulse and respiration ratio averaged 96 to 30. She perspired freely, was quite conscious, passed a natural motion and urine of 1014 specific gravity, and had some quiet sleep. Brandy was given, according to the strength of the pulse, in doses varying from two drachms to half an ounce every hour.

Some cough now appeared, with purulent expectoration. The lungs were however, resonant on percussion; but on the following day moist and sibilant *râles* became general through the lungs. The cardiac friction and apex murmur were entirely unchanged, and there was no increase of the cardiac dulness. The knees now became again slightly painful; the tongue became thickly furred, and she was occasionally sick, but took an abundance of milk, beef tea, and eggs. Lime-water was given with the milk, and within this period—*viz.*, at 3 P.M. on the 12th, or thirty hours after the last fall of temperature, being the sixteenth day of the disease, the seventh after admission, and the second of this treatment,—the pulse becoming weak and increasing in frequency to 120, quinine was again given in doses of five grains every four hours. At 8.50 P.M. on the 12th, or thirty-six hours after the previous fall of temperature, and forty-eight hours after the first rise, this had again risen to 102.1°. In thirty minutes later it had risen to 102.2°, and in order to check a further rise the ice-bag was applied to the spine. Within thirty-five minutes the temperature had fallen to 101.6° or three-fifths of a degree; in three hours it had fallen to 101°, when the ice-bag was removed. It fell another half degree in the quarter of an hour succeeding, and it then again slowly rose with minor oscillations within five hours to 102.4°, when the ice-bag was again applied for three hours, producing within this period a reduction of 1.5°. The ice-bag was then removed and a slow rise of temperature ensued during three hours and a half to 102.5°, when the ice-bag was reapplied. Its effect this time was less marked. The temperature fell in three hours 1.1°, and continued below 102° for three hours longer; but although the ice-bag was continuously applied, it rose to 102.2°, and remained nearly at this height during the succeeding three hours; then it fell three-tenths of a degree, and oscillated between 101° and 101.9° for eight hours longer, when, the temperature being only 101.6°, the ice-bag was removed from the spine, after it had been continuously applied during eighteen hours.

During this period—*i.e.*, on the third day from the attainment of the temperature of 110°—moist *râles* had appeared throughout both lungs, but had again given way to dry sibilant *râles*; abundant muco-purulent expectoration was present. The tongue was still covered with a creamy fur. The pulse had improved greatly in quality, varying in frequency from 100 to 104, while the respirations varied from 26 to 30 in the minute. The deafness disappeared on the beginning of the fourth day, though the patient was still taking quinine in doses of five grains every four hours, or at the rate of half a drachm in the twenty-four hours. The cardiac dulness remained at the level of the third cartilage. The friction continued, and also the apex murmur noticed on the 10th. There was great tenderness over the precordial region.

The patient had taken during each of the past two days eighteen ounces of brandy in the twenty-four hours, and also sixteen ounces of beef tea, four pints of milk, and seven eggs. On the fourth day of this treatment (the sixteenth day of the disease), there was some dulness at the base of the right lung; fine and coarse moist *râles* had again become general throughout the left lung, and there was some blowing breathing over the dull area in the right lung. The moist *râles* on this side were limited to this part. The temperature on this day (June 14th) varied from 101.8° to 102.8°. During an hour and a half, from 8.30 A.M. to 10 A.M., when the temperature was 101.8°, the ice-bag was applied to the spine *without any effect in reducing the temperature*. Indeed, this rose during the application to 102.1°, or three-tenths of a degree, and it was therefore discontinued, and the temperature subsequently fell during the ensuing three hours to 101.3°, after which it gradually rose during eleven hours to 103.2° (June 15th, the nineteenth day of the disease, and the fifth of this treatment).

At this time the ice-bag was reapplied for six hours, during which period a reduction took place of 1.8° in the temperature, or from 103.2° to 101.4°, when it was removed.

At this time a great improvement was noted in the patient's strength. She could turn in bed without assistance; the pulse was 96, dicrotous, but of good volume; the dulness at the right base, noted twenty-four hours had disappeared previous, though abundant moist *râles* persisted at both bases. The cardiac friction continued but the murmur at the apex had disappeared, and the precordial tenderness had diminished. The bowels had again been opened naturally. She had in the last twenty-four hours taken eighteen ounces of brandy, twelve ounces of beef-tea, and seven eggs. The brandy was now ordered to be reduced to twelve ounces in the twenty-four hours.

During the next twenty-four hours there was no further application of the cold. The temperature oscillated between 100.5° and 102.7°. The pulse remained about 96, and the respiration 24.

On the 16th (the twentieth day of the disease and the sixth of this treatment) the strength was still further improved. The tongue was still furred; but she had, in addition to twelve ounces of brandy, taken two pints of beef-tea, three pints and a half of milk, and seven eggs in the previous twenty-four hours; and had passed a natural stool. There was no dulness over the lungs, and less moist *râle*; but still some weak breathing at the right base. The pulse (96) was small, but well sustained, and without dicrotism. The cardiac friction was diminished; the apex murmur was faintly audible. She had passed seventy-two ounces of urine. The quinine was reduced to one grain every three hours, or eight grains in the twenty-four hours.

On June 17th (the twenty-first day of the disease and the seventh of the treatment) the temperature fell to 98.4°. On the following day it never rose above 99.1; and after this it remained normal, though falling on the 22nd to 97.9°.

On the 18th, though only a week had elapsed since the excessive temperature, the patient sat up in bed and ate a boiled sole for dinner.

The *râles* in the back entirely disappeared on the 22nd—the twelfth day after the intense pyrexia, and the twenty-sixth day of the disease. The heart's sounds had now become natural, with the exception of a very faint friction at the base, which disappeared within the following two days. The apex had returned to its natural position, the dulness was at the lower border of the third interspace, and there was no murmur. From this time, though the patient remained feeble for a few days longer, there was uninterrupted improvement, with the exception that on the 1st of July (the thirty-fourth day) the morning temperature was 100°. This had however fallen to 98.5° in the evening; and there was no subsequent relapse. The patient got up, walked about the ward, and was discharged for Eastbourne on the 10th of July—thirty days after the intense pyrexia, and forty-four days after she was first taken ill.

## NEURALGIA AND THE DISEASES THAT RESEMBLE IT.\*

"THE present work does not profess to be a mere compilation of standard authorities corrected down to the present time, but," as the author informs us in his preface, "puts forward a substantially new view of the subject." We have therefore read the work with especial interest, hoping to find in it an explanation of that pathological puzzle—the pathology of neuralgia, an attractive, but sorely tantalising problem, which, while stimulating the researches has baffled the ingenuity of the many physicians who have attempted to solve it. Has Dr. Anstie succeeded?

In an introduction "on pain in general," he strikes the key-note of his work. "Pain," he says, "has been described by some of the most distinguished writers on nervous diseases as a *hyperæsthesia*, yet there is really little difficulty in convincing ourselves, if we institute a

\* "Neuralgia and the Diseases that resemble It." By Francis E. Anstie, M.D., (Lond.) London and New York: Macmillan and Co., 1871.

thorough inquiry into the matter, that pain is certainly *not* a hyperæsthesia, or excess of ordinary sensory function, but something which, if not the exact opposite of this, is very nearly so" (p. 2). And again, "If pain be not a heightening of ordinary sensation, then we seem to be shut up to the idea that it is a perversion owing to a molecular change of some part of the machinery of sensation which *frustrates* function" (p. 3).

The work consist of two parts. Part I. contains five chapters entitled respectively:—*Clinical History, Complication of Neuralgia, Pathology and Etiology of Neuralgia, Diagnosis and Prognosis of Neuralgia, and Treatment of Neuralgia*. Part II. contains eleven chapters on *Diseases that resemble Neuralgia*, and which Dr. Anstie endeavours to differentiate from neuralgia itself. Without endeavouring to determine how far he has succeeded in doing so, we shall restrict our examination to Part I., because the author says Chapters II. and III. of that part "are certainly the most important portion of my book, and I would particularly direct attention to them, in order that their contents may be affirmed or corrected, the reader will, at any rate, find that they contain a kind of investigation never before systematically carried out with regard to neuralgia." We concur in Dr. Anstie's estimate of the *relative* importance of these two chapters. Chapter II., on the "Complications of Neuralgia," is undoubtedly a lucid and valuable exposition of the several remarkable and instructive phenomena which he ranges under that title, but as we find no trace of originality or novelty in that chapter, we confess to a little surprise, that the author should direct special attention to his description of phenomena, the existence and character of which are well known to every neuro-pathologist worthy of the name, and which, as Dr. Anstie himself mentions were, with a few exceptions, formally classified by M. Notta, "in a series of elaborate papers in the *Archives Générales de Médecine* for 1854." However, we cordially welcome the publication of Dr. Anstie's account of these neuralgic accompaniments as at once a concise and fairly complete description of an important group of phenomena, the production of which must be fully explained by any hypothesis which thoroughly solves the problem—what is the immediate cause of neuralgia? In his third chapter Dr. Anstie attempts to answer this question. At the beginning of that chapter he says, "I hope to show clearly, that as regards both the seat of what must be the essential part of the morbid process, and the general nature of the process itself, we possess very definite information indeed. I expect, in short, to convince most readers that the essential seat of every true neuralgia is the posterior root of the spinal nerve in which the pain is felt, and that the essential condition of the tissue of that nerve-root is atrophy, which is usually non-inflammatory in origin" (p. 110). The assertion that the posterior root of the spinal nerve is the essential seat of neuralgia, is, we think, if not strictly true, at all events very near the truth. So far, Dr. Anstie does but expound a doctrine which he holds in common with many other neuro-pathologists; but when he affirms "that the essential condition of the tissue" of the affected nerve-root "is atrophy," he propounds a theory peculiar to himself and one which, however capable of proof by facts yet to be discovered, still remains, in our opinion, wholly unproven by any evidence adduced in his elaborate chapter now under consideration. He claims for his doctrine "that the whole argument shall be taken together, for it is a case of cumulative proof; every link must be weighed and tested, before the remarkable strength of the chain can be felt." This is just what we have done: we have carefully examined every link, and we do not find one capable of sustaining the remarkable proposition in question. In other words, we do not find a single argument proving it to be even probably true, and as no chain can be stronger than its weakest link, our consideration of "the whole argument taken together" has not wrought in us that conviction which an examination

of each separate part failed to produce. We confess that we are not surprised; for while fully recognising Dr. Anstie's undoubted ability, and his extensive acquaintance with his subject, we believe that he has attempted an impossibility. Nothing that he has said shakes our conviction—a conviction held, we feel assured, by nearly every medical man who has thought on the subject—that the condition of the centrepetal end of every sensory nerve affected with neuralgia is diametrically opposite to that described by Dr. Anstie. Within the space at our disposal we cannot discuss the several arguments he adduces, but we cannot help remarking that any seeming strength which they may have is mainly imparted to them by the ingenuity with which, while the simple, *primâ facie*, significance of established facts is ignored, a new and far-fetched meaning is given to them so as to enable them to yield an apparent support to the author's original theory. And here we must express our astonishment in observing that he is actually so far enamoured of that theory as to have become wholly unable to see how the simplest "peripheral influences" which "become factors in the production of neuralgia" produce that effect. Of such influences nerve-wounds are good examples, and surely no influences are more likely than these to exert an *irritating* and *exciting* effect on the nerve-centres in which the wounded nerves are rooted; but recognising this truth would be recognising a powerful argument adverse to Dr. Anstie's theory: he simply ignores it, and says, "the only common quality that can be predicated of all [these peripheral influences], is their tendency directly to *depress*, the life of the sentient centre upon which their action impinges" (!). Truly, "love is blind" in more senses than one.

The numerous complications of neuralgia which, as already said, Dr. Anstie has very well described, are either unexplained, or explained in an unsatisfactory manner by his hypothesis; indeed the "trophic phenomena"—the inflammations, for example, which are frequent accompaniments of neuralgia, stand in such stubborn opposition to it, that its author (at page 153) virtually confesses himself puzzled, and is obliged to invent a supplementary theory to help him out of his difficulty.

As already intimated, Dr. Anstie has, in our opinion, attempted an impossibility, and therefore that he has not succeeded in his attempt, is no discredit either to his natural ability or to his professional acquirements. And indeed we feel no regret that his doctrine—that the posterior roots of the affected nerves in cases of neuralgia are in a state of atrophy—is insusceptible of proof, is probably, in fact, the very reverse of the truth; for certainly it is a very comfortless, and indeed, hopeless doctrine, and one which affords no kind of trustworthy and faith-inspiring indication of rational treatment. Accordingly, on turning to Dr. Anstie's chapter on treatment, we only find but one suggestion which is a logical development of the author's theory, viz., that the constitutional strength of the patients should be increased as much as possible by an ample supply of food, including an abundance of fatty matters, and by a free use of tonics. The rest of the chapter enumerates the usual list of empirical remedies long employed with but little success in the treatment of the malady, and while especially commending hypodermic injections of morphia and atropine, dwells at length and with great emphasis on the remedial excellence of galvanism.

In taking leave of Dr. Anstie, we cordially thank him for his scholarly, very readable and decidedly interesting book; for though we are constrained to say that it contributes absolutely nothing to our knowledge of either the pathology or treatment of neuralgia, we feel sure that it will set many of its readers thinking, and its effective agitation of the obscure, but very important subject to which it is devoted, can scarcely fail to contribute, at least indirectly, to achieve the end which its earnest and gifted author has in view.

## Correspondence.

### REGARDING THE REAL AUTHORSHIP OF THE CIRCULATION OF THE BLOOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A short time since, I happened to take up a copy of Longinus "On the Sublime," in the thirty-second section of which where he speaks of the use of the metaphors and tropes, I find a quotation from Plato "On Human Anatomy."

On the opposite page I send you the quotation in the Greek text, of which the following is a strictly literal translation:

"By means of these (tropes), has the anatomy of the human body been so magnificently described by Xenophon, and even still more Godlike by Plato?"

"The head of man he calls a citadel, and says that the neck is placed in the centre between it (the head), and the chest like an isthmus, and that the vertebrae were fixed underneath like hinges, and, also, that pleasure is to man the attraction to evil, and that the tongue is the index of tastes; but the heart being a knot of veins, and the source of the rapidly circulating blood (*καὶ πηγήν τῶν περὶ φερούμενου ὀφθαλμοῦ ἀμαρτος*) is assigned a place in a well guarded situation. The course of the pores he calls narrow streets. But the Gods devising a protection against the pulsations of the heart in the expectation of danger, and against the excitement of the mind when it would be inflamed with wrath, conceived, he says, the idea of implanting the lungs, soft and bloodless, and having within them numberless cavities, like a malagma, in order that the heart, when the mind would seeth within itself, striking against a yielding substance would not injure itself. The seat of the sensual passions he calls the apartment of women, and that of anger, the apartment of men, and the spleen, the image of the entrails whence, when filled with excrements is greatly enlarged, and becomes soft. But after this, he says, they (the Gods) covered all parts with flesh, having placed the flesh as a protection against external agents, and says that, for the sake of nourishment they formed a system of blood vessels in the body, cutting channels, as is done in gardens for their irrigation, that from a fixed source, the body being weak, the rivulets of blood would be in continual movement (*τὰ τῶν φλεβῶν ζοι νάματα*). But when death approaches he says the cables of the soul, like those of a ship, are relaxed, and that she is permitted to go perfectly free."

Hitherto, I had implicitly believed that Harvey was the real discoverer of the circulation; but now my belief is entirely changed, and I am perfectly convinced that the ancients were quite conversant with the fact of the circulation. See what an immense space of time there is between Plato and Harvey, the former lived 395 B.C., and the latter died A.D. 1657, leaving an interval of 2,052 years. Now, Sir, I shall feel very thankful to you for your full and candid opinion on this important subject, and would be glad to see it discussed by some able readers of the MEDICAL PRESS.

J. J. McKEOGH, L.R.C.P.

Thurles, 17th Nov., 1871.

P.S.—Is it not very reasonable to think that at the time Plato lived, the word *φλεβῶν* may have been used to mean both veins and arteries?

### DRAINAGE AND FEVER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—His Royal Highness the Prince of Wales is suffering from typhoid fever—such is the announcement in the daily papers—and it suggests serious reflections as to the causes and prevalence of this insidious class of diseases.

In this case it is supposed to have been produced by impure water; but we cannot shut our eyes to the fact that for some years past there has been a general increase in typhoid and low fevers during cold weather, and the question naturally presents itself—What is the cause of it?

It has popularly been considered that cold, clear, or, as commonly expressed, "bracing" weather, invigorated the system and purified the atmosphere; but recent observations qualify our opinions. A spell of cold weather—unseasonable perhaps, but not otherwise unusually severe—has again developed fevers

of a typhoid character, not only amongst the poor, but, as shown above, amongst the highest in the land.

I am disposed to attribute this to the increased luxuriousness of our habits and the extension of so-called sanitary regulations. The drainage has been extended until every house is supposed to be in direct communication with the sewers in most towns, and in the better class of houses an upper in-door closet is a *sine qua non*. Have these anything to do with it? Is it not probably that when, to keep out the cold, every window and other aperture by which pure air could gain admission is carefully closed, we are admitting a foetid atmosphere into our houses, that our sleeping rooms are reeking with the foul air from the drains, which, pouring from the defective traps and gullies at the basement, gradually ascends to the upper rooms, permeating the whole house, and breeding fevers and poisoning our blood?

This is a subject which should engage the attention of the profession, and is worthy a place in your columns.

A. B. S.

## OBITUARY.

DR. JOHN DEMPSTER,  
INSPECTOR-GENERAL OF HOSPITALS.

THIS able medical officer, who held one of the good-service pensions, died on the 13th inst. at Edinburgh, having served about forty-five years on full pay, nearly thirty-four of which were passed on foreign service. He entered the service in 1813, and, under the provisions of the Royal Warrant of 1858, was placed on half-pay in January, 1859, having attained the age of sixty-five years. He was much esteemed both in and out of the service.

CALEB WILLIAMS, M.D., F.R.C.S.

THIS gentleman who died on the 5th inst., in the seventy-third year of his age, was the oldest member of the medical profession in York. He was in high repute as an alienist, had had much asylum experience; and occupied the chair of Materia Medica and Therapeutics in the York School of Medicine, now closed for many years. His work "On the Criminal Responsibility of the Insane" appeared in 1856, and was much thought of by the profession.

MR. DE LA GARDE, F.R.C.S.

ANOTHER eminent Exeter surgeon has been removed by death. On Friday afternoon Mr. Philip Chilwell De la Garde, F.R.C.S., died at his residence, Southernhay, at the age of seventy-four, from inflammation of the lungs. The deceased gentleman was the son of the Rev. Philip De la Garde, Rector of St. Martin's, Jersey, and belonged to an ancient and honourable family. He was educated at the Exeter Grammar School under the famous Dr. Lempriere, the then head master, whose daughter he afterwards married. After leaving school he became the articulated pupil of Mr. Patch, a surgeon of high repute in Exeter. Mr. Patch died during his pupilage, and was succeeded by the late Mr. Barnes, with whom Mr. De la Garde completed his term. He afterwards entered Bartholomew's Hospital as a student, and while there was a pupil of the celebrated Abernethy. He distinguished himself at the hospital, and served the office of house-surgeon, on resigning which he returned to Exeter, where he practised about half a century. In the earlier part of his career he was one of the medical officers of the Corporation of the Poor. In the year 1841, he was elected to the post of surgeon to the Devon and Exeter Hospital, succeeding Mr. Incombe, and became senior surgeon of that noble Institution on the death of the late Mr. James. For about thirty years he was surgeon of the Devon and Exeter Eye Infirmary. To the diseases of the eye he applied himself with special success, and wrote a work on Cataract which was highly prized. Mr. De la Garde was perhaps the most accomplished anatomist in this division of the kingdom, and as a consequence a surgical operator of superior skill. He filled the office of Sheriff of the city as far back as 1832, and that of Mayor in 1834. To antiquarian studies he

was much attached, and as a member of the Devon and Exeter Architectural Society read many papers on archaeological subjects. Of scientific engineering he had also considerable knowledge, and it is related of him, that he warned Brunel of the perils to which his new line along the South Devon Coast would be exposed. The great engineer laughed at the advice given to him, but the apprehensions expressed were soon after confirmed by the washing away of a bridge and a portion of the railway. Mr. De la Garde made no parade of generosity, but those who knew him best speak warmly of his goodness of heart, and of the kindness shown by him to persons of restricted means when stricken down by illness. He was, says the *Exeter Gazette*, an English gentleman of the good old fashion; punctilious even in his observance of the unwritten laws of honour. He was more than a Conservative, he was a Tory of half a century back,—high-minded and independent, staunch to his principles, and of sterling integrity. The deceased's only son, a talented and promising member of his father's profession, died a few years ago.

### H.R.H. THE PRINCE OF WALES.

THE Prince of Wales lies ill at Sandringham with typhoid fever. Exactly ten years ago his father died at Windsor from the same disease, and there are physicians who think that some constitutions are more liable to it than others. If the disease runs a most favourable course, it will yet last another week, and the debility it leaves behind is often profound and prolonged. Then there are many sequelæ from which such patients too often suffer, and to which not a few succumb. We cannot then, but regard the case with anxiety. In these days of foolish speeches about the uses of royalty, the country is as profoundly anxious as ever, and the serious illness of the Heir to the Crown excites questions in all directions. Is the water at fault? is the first thought of all imbued with modern doctrines, and if others were simultaneously seized who were supplied from the same source, would be most important. It will be regarded in all medical circles as satisfactory that Sir William Jenner has been called in. As long ago as 1846, Sir William, then Dr. Jenner, began a series of investigations into this disease which have greatly contributed to the exact knowledge we now possess, and with which his name will be always most honourably associated. No living physician has a greater claim to the confidence the profession reposes in him, in reference to his intimate acquaintance with fever, and all will, we are sure, find comfort in the thought, that the Heir-apparent has the benefit of his care. Still, even the greatest authority on fever cannot perform impossibilities, and we should but be wilfully blind did we refuse to see cause for grave anxiety. We annex the latest bulletin from the telegrams as we go to press. "Nov. 27 (7 p.m.) His Royal Highness the Prince of Wales has passed the day more tranquilly. There is no important change in the symptoms since morning."

## Medical News.

**Royal Society.**—At the annual meeting of the Fellows of this Society, to be held on St. Andrew's Day, at Burlington House, the following gentlemen will be nominated:—President, George Biddell Airy, D.C.L.; treasurer, William Spottiswoode, M.A.; secretaries, William Sharpey, M.D., LL.D., and Professor George Gabriel Stokes, M.A., D.C.L.; foreign secretary, Professor William Hallowes Miller, M.A., LL.D. Other members of the Council:—George James Allman, M.D., John Ball, M.A., George Burrows, M.D., George Bask, President R.C.S. Eng.; Prof. Robert Bellamy Clifton, M.A.; Heinrich Debus, Ph.D.; Prof. Peter Martin Duncan, M.B., Professor George Carey Foster, B.A., Mr.

Francis Galton, Thomas Archer Hirst, Ph.D., Sir John Lubbock, Bart., Sir James Paget, Bart., D.C.L., F.R.C.S., the Earl of Rosse, D.C.L., General Sir Edward Sabine, K.C.B., Isaac Todhunter, M.A., and Sir Charles Wheatstone, D.C.L. The Council will present the gold medals in their gift to Mr. George Bask, F.R.S. and President of the Royal College of Surgeons; the Copley medal to Mr. Julius Robert Mayer, of Heilbronn; and the remaining Royal Medal to Dr. John Stenhouse, F.R.S.

**Small-pox.**—At a meeting of the Shoreditch vestry, a resolution previously passed providing for the sale of the wooden building temporarily used as a small-pox hospital in the Hackney road has been rescinded. The principal argument against the original resolution was that the distribution of the materials of the building would probably disseminate the disease throughout the district.

**Royal College of Surgeons in Ireland.**—At the meeting of the Council held on the 16th inst., Dr. W. Handsel Griffiths, Ph.D., L.R.C.P., and L.R.C.S.E., was elected Assistant-Librarian of the College.

### An Enormous Collection of Earthy Matter in a Human Lung. By V. Gorup-Besanez.

THE two cases were under the care of Prof. Zenker; V. Gorup-Besanez made the chemical examination of the lungs. One was a woman who was employed in the manufacture of the books of thin red paper in which gold-leaf is placed. Fifty-seven grm. of one lung was incinerated, the ash treated with muriatic acid and examined for oxide of iron, of which 0.828 grm. were found. Supposing the oxide equally distributed through both lungs, the total amount would be between 21 and 22 grm.

The second case was a manufacturer of ultramarine. Two hundred and twenty-seven grm. were incinerated and the ash remaining gave 3.1,935 grm. siliceous sand, 0.3,298 grm. quartz sand, and 0.329 grm. of oxide of iron.

Considering the total weight of both lungs 1,500 grm.; and these substances to be equally distributed, the total weight of sand, &c.; would be 29.86 grm.—*Annalen d. Chemie u. Pharmacie.*—*Med. Chir. Rundschau*, July 1871.

### Spasmodic Muscular Contraction.—Arterial Compression.

M. BROCA had under his care, a few months ago, in the Hôpital de la Pitié, a man who had broken both bones of his leg an hour before his admission to hospital. The muscular contraction was so violent that it was impossible to reduce the fracture. M. Broca thereon employed a method which he had found successful in cases of painful cramps of the lower limbs, viz., compression of the femoral artery. Almost immediately the muscles became relaxed, and reduction was effected with ease. Subsequently, in re-applying the splints, the contraction returned, and was again overcome by the same means. The *Journal de Médecine et de Chirurgie Pratiques* for March, in relating the case, says that the simple and easy means employed by M. Broca ought always to have a trial before giving chloroform, which is often done in such a case.—*N. Y. Med. Record*.

### Case of Superfoetation.

In the *Wiener Allg. Med. Zeit.*, a case of superfoetation is given by Schusta, of Seiden. A robust woman, of twenty-six, was delivered, after tedious labour by forceps. The placenta came away in three-fourths of an hour, and on carefully examining it, a second anniotic sac was found, which contained a male foetus, nine inches long, and which weighed five ounces.

### Tapping in Strangulated Hernia.

DR. DOUGLAS MORTON (*Richmond and Louisville Med. Jour.*) reports two cases treated by introducing a canula needle into the hernial tumour, and evacuating such of its contents as can be made to pass through such a channel. The first of the cases occurred in the practice of Dr. D. Cummins. It was of a large and tense serotal hernia, and the patient a negro boy. The instrument employed by Dr. Cummins was a hollow needle, made for applying sutures in vesico-vaginal fistula. Immediately on introducing this instrument, the gas, which distended the bowels, gushed out, relaxing the walls of the loop, and rendering reduction a matter of the utmost ease. The patient was up the next day, and suffering no bad results from the operation.

## NOTICES TO CORRESPONDENTS.

To the Editor of "The Medical Press and Circular."

DEAR SIR,—I find there is an error in the percentages in two places in my address to the Dublin Obstetrical Society, reported in the last number of the MEDICAL PRESS, and though it does not materially affect the argument, and the whole numbers are correct, I shall feel obliged by your allowing me to rectify the error.

It is stated that Dr. Clarke lost 72.38 per cent. of the whole number of children born after tedious and difficult labours, and Dr. Collins 42.80. It should be, that Dr. Clarke lost 53.003, and Dr. Collins 53.809 per cent.

I am, yours truly,  
GEORGE H. KIDD.

MR. HINCLIFF will please receive our thanks.  
MR. GUNSON, Scarborough.—We make it a rule never to recommend any particular practitioner through our columns. The gentleman named by you is duly qualified, and would doubtless give every attention to your case.

MATERIA-MEDICA.—The work you mention is published by Messrs. MacLachlan and Stewart, Edinburgh.  
J. S. B.—Not later than Mondays.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.  
Text Book of Skin Diseases. By Dr. Isidor Neumann. Translated by Alfred Pullar, M.D. London: Hardwicke.  
On Clinical Education. By Fumiaux Jordan, F.R.C.S. London: Churchills.

General Representation. By A. E. Dobbs, M.A. London: Longmans.  
First Report of the Medical Committee of the Charity Organisation Society.

The Royal London Hospital Reports, Vol. VII.  
Le Mouvement Médical; The Glasgow Medical Journal; La Presse Médicale; La France Médicale; Bulletins Della Scienze Mediche.

## VACANCIES.

Female Orphan Asylum, Beddington, Surrey. Honorary Physician. Stockport Infirmary. Assistant-Surgeon. Salary £60, with board. South Stafford Hospital. Assistant-Physician. Salary £100, with board.

University College Hospital, London. Assistant Obstetric Physician. Brompton Consumption Hospital. Resident Clinical Assistant. Great Northern Hospital, London. Honorary Surgeon. Farringdon Dispensary, London. Resident Surgeon. Salary £75. Liverpool Royal Infirmary. Honorary Physician to the Infirmary, and the Demonstration of Ophthalmology. Carnarvon Infirmary. House-Surgeon. Salary £80, with board.

## MEETINGS OF THE LONDON SOCIETIES.

WEDNESDAY, Dec. 29th.—ROYAL SOCIETY OF ARTS, 8 P.M. Paper by W. Bridges Adams.

Friday, Dec. 1st.—ST. ANDREW'S MEDICAL GRADUATES' ASSOCIATION, 7 P.M.—"Habitual Drunkenness and its Treatment," by Dr. Horace Swete.

Saturday, Dec. 2nd.—ST. ANDREW'S MEDICAL GRADUATES' ASSOCIATION, 5 P.M.—"The Historical Steps of Modern Medicine," by Dr. Hy. Day.

Monday, Dec. 4th.—MEDICAL SOCIETY, 8 P.M. Ordinary.

Tuesday, Dec. 5th.—PATHOLOGICAL, 8 P.M. Ordinary.

## OPERATION DAYS AT THE LONDON HOSPITALS.

WEDNESDAY, NOV. 29.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

## APPOINTMENTS.

ALLEN, T., L.R.C.P., House-Surgeon to the Great Northern Hospital.  
COOPER, A., F.R.C.S., Assistant Surgeon to the West London Hospital; Surgeon to Out-Patients at the Lock Hospital; Assistant Surgeon to St. Mark's Hospital for Fistula; to the Inns of Court R.V. and Surgeon to the Royal Hospital for Diseases of the Chest, City road.

CAVE, L., M.B., Clinical Assistant to the Hospital for Women, London.  
HAYARD, D., L.R.C.P.L., Admiralty Surgeon and Certifying Factory Surgeon for Newport, Pembrokehire.

HUSBAND, W. D., F.R.C.S.E., J.P., Visiting and Consulting Medical Officer to The Retreat Lunatic Asylum, York.

KEYS, R. A., L.R.C.P. Ed., Resident Medical Officer at the Toxteth park Workhouse, Liverpool.

MILLIGAN, J., M.R.C.S., Medical Officer of Health for Keighley, Yorks  
NEAL, Breward, L.R.C.P. Ed., Assistant Medical Officer to the Cornwall County Asylum.

PHILLIPS, S. R., M.D., C.M., Assistant Medical Officer to the Devon County Asylum.

PIERS, Mr. C. E., Assistant House-Surgeon to the Cumberland Infirmary.

WELLS, J. S., M.D., Consulting Surgeon to the Shropshire Eye and Ear Hospital, Shrewsbury.

WILLIAMS, I. M., M.R.C.S.E., Visiting Medical Officer to the Lawrence House Lunatic Asylum, York.

WIMBERLEY, C. C., M.D., Honorary Surgeon to the Coventry Hospital.

## Marriages.

COVEY—MORTON.—On the 15th inst., at Dring-house, York, Edward Rogers Covey, son of the Rev Charles Covey, of Alderton, to Emily, youngest daughter of the late Hugh Morton, Esq., M.D., of Newark-on-Trent, Notts.

AYERILL—GOODWYN.—On the 18th inst., at Tetbury, Alfred Ayerill, M.R.C.S., to Maria Anne Goodwyn, daughter of J. G. Goodwyn, Esq.

BARWELL—SHUTTLEWORTH.—On the 15th inst., at Christ Church, Preston, Richard Barwell, F.R.C.S.E., of George street, Hanover square, to Mary Diana, daughter of Thomas Starkie Shuttleworth, Esq.

JOTHAM—WARWICK.—On the 16th inst., at Southend, George W. Jotham, M.B., of Kidderminster, to Edith, daughter of W. R. Warwick, M.D.

## Deaths.

DAVIS.—On the 17th inst., at Tottenham, Robt. Wm. Davis, M.R.C.S.E., formerly of Finsbury, in his 63rd year.

DE LA GARDE.—On the 17th inst., Philip Chilwell De la Garde, F.R.C.S.E., of Southernhay place, Ex-ter, aged 74.

GREENWOOD.—On the 22nd inst., at Talbot place, Blackheath, Henry Greenwood, M.D., in the 79th year of his age.

STEGGALL.—On the 21st inst., at Southampton street, Bloomsbury square, Dr. J. Steggall, Medical Tutor.

## The Medical Press and Circular

OFFERS UNUSUAL ADVANTAGES

FOR the Insertion of announcements, from its extensive and largely increasing circulation in each of the three divisions of the United Kingdom and the Colonies. Being also supplied to the Hospital Libraries, &c., it will be found a most valuable medium for Advertisements of Books, Vacancies and Appointments, Sales and Transfers of Practices, Surgical Instruments, Chemicals, and Trades generally.

The scale of charges is as follows:—

|                             |        |
|-----------------------------|--------|
| Seven lines and under ..... | £0 4 0 |
| Per line afterwards .....   | 0 0 6  |
| One quarter page .....      | 1 5 0  |
| Half-page .....             | 2 10 0 |
| One do. ....                | 5 0 0  |

When advertisements are given for a series of insertions, a very considerable reduction from the above scale is made.

Advertisements for Insertion in this Journal must be at the OFFICE, on SATURDAY, by Two o'Clock.

ST. ANDREW'S MEDICAL GRADUATES' ASSOCIATION.—The Fifth Anniversary Session will be held at the Freemasons' Tavern, Great Queen street, on Friday and Saturday, December 1 and 2.

On the 1st, at 7 P.M., the business of the Association will be transacted, after which Dr. Swete will open a discussion on "Habitual Drunkenness and its Treatment, Medical and Legislative."

On the 2nd, at 5 P.M., the President, Dr. Day, of Stafford, will deliver the Anniversary Address, "The Historical Steps of Modern Medicine." The dinner will be held at 6 P.M.

LEONARD W. SEDGWICK, M.D., Hon. Sec.

## INDIAN MEDICAL SERVICE.

NOTICE IS HEREBY GIVEN, that an Examination of Candidates for at least 40 appointments as Assistant-Surgeons in Her Majesty's Indian Medical Service will be held in London in February, 1872.

Copies of the regulations for the examination of Candidates, together with information regarding the pay and retiring allowances of India Medical Officers, may be obtained on application at the Military Department, India Office, Westminster, S.W.

The applications of Candidates for examination will not be registered at the India Office till after the 7th January 1872.

T. T. PHARR, Major-General,  
Military Secretary.

India Office, Nov. 16th, 1872.

## LECTURES ON EPILEPSY

DELIVERED IN THE

### LEDWICH SCHOOL OF MEDICINE,

By HENRY EAMES, M.D., Dub. L.C.P., &c.

Physician to Mercer's Hospital, Joint Lecturer on the Practice of  
Medicine, Ledwich School, &c.

(Continued from page 476.)

NOTHING can more clearly show the unsatisfactory results of treatment as applied to epilepsy, than the long list of various medicines at different periods vaunted as specifics. Though in many, nay in most, cases of the disease you will entirely fail of cure; yet, that in some cases success has been obtained must encourage you in your contest with the malady. Had we an exact knowledge of its pathology we should then be in a position to determine on a rational line of treatment. But this is not so. The nearest approach to such knowledge is the discovery of the hyperæmic state of the medulla oblongata. On this is founded that treatment recommended by Van der Kolk, of repeated leechings of the nape of the neck, or vesication of the same part, or the inunction of pustulating salves. The rationale of this *modus operandi* is their derivative action from the congested medulla. Be the theory true or false, undoubtedly brilliant results have occasionally followed the adoption of such means. Three or four leeches applied once a fortnight, and the bleeding after their removal encouraged by elastic cups, or warm stupes will, in some cases, marvellously diminish the number and violence of the fits. But though this topical bleeding be useful, I am reminded to warn you against general blood-letting, or venesection. This latter will almost always prove positively injurious to your patient.

Whatever specific treatment you may purpose finally to adopt, you will do well as a primary measure to foster and improve the health of the patient. You will take care that there be no excessive or long continued mental, or bodily exertion. That exercise and food be regularly and

moderately taken. That an epileptic boy or girl do not sit for six or eight hours at lessons; at the same time you would not enforce absolute idleness, since the mind, as well as the body, requires pabulum and exercise for its growth. You will ascertain whether excessive venery, masturbation, or intemperance be indulged in, and if they should, you will compel by every available means their relinquishment. If anæmia be present, you will, I presume, employ iron in some form. You will direct your patient at the same time to take proper hygienic measures, to live in a pure atmosphere, to eat meat twice or three times a day, and possibly to use the cold sponge bath. Shower baths do not usually agree well. Bathing in the open sea you must interdict both on account of its tendency to induce cerebral congestion, and lest a fit might come on during bathing, and the sufferer be drowned. This is no idle warning since such untoward accidents have occurred.

Should you find a plethoric state of body you will permit meats but sparingly, and vegetables will form the main portion of the diet, whilst water will be the beverage.

Strumous subjects you will no doubt treat with cod-liver oil and such remedies as you may deem advisable for that diathesis.

It has been mentioned that worms, cicatrices and tumours are occasionally the excitants of the malady. It need hardly be insisted on, that should such cases present themselves, you will endeavour to remove the *origo mali*. That the disease sometimes persists, despite such removal, would be no sufficient reason for neglect. Obstinate epilepsy subjected to varied specific treatment has entirely ceased on the passage of a tapeworm; and a similar happy result has followed the excision of an old cicatrix, or the extirpation of a neuroma. Do not, however, fall into the other extreme of encouraging the too sanguine hopes, doomed perhaps to disappointment, of an epileptic patient in whom you have discovered a tenia.

Where you have reason to suspect the existence of uterine derangement you will make a proper and searching examination, and should your suspicion prove correct, you will devote yourself to its removal. Ulceration of the os uteri, a polypus within its cavity, as well as other diseased

states, have often been the starting points of both forms of the comitial disease.

This, perhaps, is the fittest place to allude to the operation of clitoridectomy advocated by Dr. Baker Brown as a cure for epilepsy in the female sex, when the disease owes its origin to self-abuse. This author believes that there exists a morbid irritability of the extremity of the nerve supplying the clitoris, and that by the extirpation of this organ the starting point of the disease will be removed. This plan of treatment has not met with much favour, and few physicians, I think, will agree, that the pernicious habit, to which allusion has been made, exists to the extent that is presupposed.

Amongst the remedies employed in the specific treatment of epilepsy the first that claims our attention is bromide of potassium. This is of modern use, and indeed of recent discovery, bromine being first discovered in the year 1826. Bromine alone, or potassium alone have no useful effect on the disease, it is from their combination that such excellent results are not unfrequently obtained. You will commence its administration in ten grain doses three times a day, and may gradually increase the amount to one or two drachms in the twenty-four hours. The latter quantity I have rarely exceeded. In certain cases the smaller doses will have little effect. You may find it necessary to press the drug to the production of what is termed bromism before good results are obtained. By this term we mean the specific effects of bromide in chemical combination with potassium, sodium, or lithium. They may be briefly stated as redness of the palate, swelling of the mucous membrane of the mouth and nose, with salivation and lacrymation, heat and burning in the epigastric region, mental confusion and drowsiness with depression and failure of memory, and weakness of the limbs. Acneiform eruptions also occasionally follow its use. None of these disagreeable effects of the drug are permanent, and quickly disappear when its administration is stopped.

We are hardly at present in possession of sufficient data to enable us to predicate with any certainty in what cases of the comitial disease this remedy will prove successful. From the anaphrodisiac properties of the drug it is presumable that those cases into the history of which excessive venery or masturbation enters are the most likely to be benefited by its administration, and my own observations would lead to this conclusion. It has lately been stated that fits arising from injuries and jars to the pericranium are especially amenable to the curative action of the bromide, whilst in the congenital or hereditary form it has no efficacy.

Many of you have seen at Mercer's Hospital cases thus treated. I would recall to your recollections the case of a lad, aged nineteen years, who himself assigned onanism as the source of his disease. He was treated with bromide of potassium alone for more than a year, taking it latterly a drachm and half every day. The fits, which used to occur four and five times a week, were almost from the first diminished in number and violence. After he had taken the drug for six months they ceased altogether. He thought himself cured, and no longer attended. The malady, however, soon recurred, and he again placed himself under our care. He took the bromide steadily for nearly six months more, a drachm and then a drachm and a half each day, and is now I believe completely cured, treatment being stopped for nine months, and no fit having, in the meantime, occurred.

The bromides of sodium and lithium have also been recommended, more especially the former. Their good effects do not appear to equal those of bromide of potassium. The salt of sodium may be given in ten grain doses three times a day gradually increased to twenty-five grain doses. It produces less gastric irritation than bromide of potassium; but in other respects the symptoms induced are alike.

When administering bromide of potassium, or any other medicinal agent, for the cure of the comitial disease you must remember that the malady is chronic, and is not to

be overcome by hasty and uncontinued assaults. That no good effects are visible after it has been taken for some weeks will be no valid reason for its relinquishment. Perseverance is essential to success.

The next drug, to the use of which I would ask your attention, is belladonna, and its alkaloid atropia. The late M. Trousseau, the great advocate for this form of treatment, insists much on the necessity for long and unremitting continuance in its employment. It is not for six or twelve months, it is for years that it must be given. The system must be continuously kept under its dominion, bearing in mind that the germ of the disease has probably existed from birth. You may administer the drug thus: one pill, composed of extract of belladonna and the powdered leaves, of each one-fifth of a grain, to be taken every day during the first month; two such pills during the second month, increasing each month the dose by one pill. These are to be given together and precisely at the same hour each day. The limit to which you may push the remedy is marked by its toxic effects. Excessive dilatation of the pupils and dryness of the fauces are hints you must not neglect. If the system do not readily bear the drug, your increase will be more gradual, a pill being added only every second, third, or fourth month. When permanent good results have been attained, you may continue for some time the dose then reached, and gradually diminish it at the same rate at which you had increased it.

A solution of atropia may be substituted for the above pills. One minim of a solution of two grains of atropia in two drachms and a half of rectified spirit will correspond to one of the above pills. The same rules will apply to its administration.

The hypodermic injection of atropia in the track of the aura might be followed by good results. I merely throw out this as a suggestion. The dose should, of course, be minute, and persisted in day by day.

Opium, and its alkaloid morphia, are of ancient fame, though now little used. Indeed, the whole class of sedatives and narcotics would be theoretically contra-indicated, since we are not called on to relieve pain, but subdue excessive reflex irritability. This the narcotics tend to increase. Digitalis, which acts so powerful on the circulation, has been used to some extent abroad, and favourable results are claimed for it.

Nitrate of silver has also been much employed. One to four grains may be given each day after meals. You must be very careful not to produce the bluish staining of the skin which sometimes results from its continued use. The earliest symptom of this is a greasy appearance on the skin of the faces; should you observe this, you will at once cease its administration.

The preparations of zinc are still occasionally used: the oxide, sulphate, valerianate, acetate, lactate and cyanide. They are most successful in young subjects, and in those of a highly nervous organisation. They should not be pushed to the extent of producing *spanæmia*, which often follows their prolonged administration.

The ammonio-chloride and the sulphate of copper have also their advocates. Trousseau suggests that whilst belladonna is continuously given in the mornings, the salts of silver, zinc and copper may be given in the evenings, each for ten days at a time. I have no experience of this method; but every suggestion coming from so excellent a physician is worthy of attention.

Phosphorus, which acts so powerfully on the nervous system, has been used with success in epilepsy. I am not as yet in a position to speak from extended experience of its effects in this disease, but from the benefit which I have observed to follow the employment of this drug in other neuroses, I would anticipate most favourably concerning it. It may be given dissolved in oil inclosed in capsules which may be procured from Messrs. J. J. Graham and Co., Westmoreland street.

You are probably aware that a powerful action can be exercised on the spinal cord and the collateral ganglia of the sympathetic nerve by means of ice applied over the

spine. The circulation, and consequently the energy of the nervous centres acted on, is much lessened by the application of the spinal ice-bag. It is claimed that convulsive seizures can thus be checked, and a permanent good effect be induced by its continuous use. To Dr. Chapman belongs the merit of having brought this form of treatment into general use.

The constant galvanic current is now by some employed as a curative agent. It may be used whilst other medicinal treatment is persisted in. The parts to which it is applied are the brain, spinal cord, and sympathetic nerve. The electrodes are to be placed, the positive on the forehead, the negative on back of the neck for four minutes. Then they are to be placed for the same length of time on the mastoid processes, and lastly, the positive pole is to be applied over the sympathetic in the neck, and the negative over the third or fourth dorsal vertebra. The current should be a strong one. One derived from twenty cells of Daniell, Smees, or Le Clanche will suffice. The applications should be repeated three, or four times a week.

Valerian, artemisia vulgaris, santaline, turpentine, strichnine, arsenic, musk, ergot of rye, and guaiacum, are selections from the remedial agents, which in addition to those already mentioned, you will find recommended for the treatment of epilepsy.

M. Brown-Séquard recommends that the starting point of the aura should be sought for most diligently in all epileptics, both in those in whom it palpably exists, as also in those in whom a superficial examination may not discover it. Pressure, tickling, and the passage of the galvanic current may induce a fit in persons who were supposed to be unaffected by auras, and this only when a particular part is acted on. Ligatures isolating a member or limb; actual cautery, issues, or potassa fusa applied to the ascertained locality whence the aura originates, have brought about a cure of the malady. This result, strange enough, has been obtained even in cases where there could be no doubt as to the central source of the malady. In using these measures you must bear in mind the fact that the fit deferred from time to time by ligatures and the like, appears occasionally to gather, as it were, an accumulated force, and indeed now and then proves fatal. Such was the termination of Odier's case, and many others.

The epileptic should have constant care, and, when circumstances admit of it, he should have an attendant devoted to himself. He should not be allowed to go into positions where, should an attack occur, dangerous results might ensue. He should avoid excitement and crowds. His bed should be provided with sides, lest he should fall to the floor. He should not sleep in a room by himself lest, turning on his mouth in a fit, suffocation might result.

During the fit, the inhalation of chloroform has been favourably spoken of by some. In the hands of others it has not been so successful. It has no curative effect on the disease. There are certain cases, however, in which you will find this anæsthetic of great use. It will lessen the clonic spasms of the respiratory muscles, which tend to prolong the stupor following the fits. It will also be of service in those cases in which maniacal attacks succeed the seizure; and should a limb be fractured, by averting an expected attack, time may be gained for the formation of callus.

If the fit be very violent and long continued you may succeed in arresting it by pressure on the carotids. This operation is difficult to perform during the fit, and requires careful manipulation. Generally, during the paroxysm, a few simple measures will suffice. The head should be raised above the level of the body, the collar and necktie loosened and a piece of soft wood placed between the teeth to save the tongue from injury. You will of course take care that in his struggles and writhings your patient does not place himself in a position of peril.

## Original Communications.

### NOTES OF MIDWIFERY CASES.

By J. M. Hyslop, M.D.,

Late Professor of Midwifery, Grant Medical College, Bombay.

FEBRUARY 22ND, 1863.—A case of retained placenta after a natural labour, which terminated five hours before seeing the patient; little hæmorrhage; os uteri of the size of a crown piece, and a portion of placenta protruding; the cord had been pulled away with a portion of placenta adhering. Hand introduced into uterus, and placenta found to be strongly adhering to the right side of the uterus near the fundus; it was almost entirely detached and brought away, but with much difficulty. There was high fever for some days; a small portion of placenta was expelled without hæmorrhage, and the woman recovered perfectly.

February 23rd, 1863.—A Parsee woman. A six months' foetus having presented by the feet was pulled away and detached from the head, which was left in the uterus. Before admission os uteri swollen and contracted, and upper lip torn and ragged; no pains; pulse good. Several doses of ergot were given without effect; after a dose of morphia, which procured several hours sleep, she had a pain which expelled the head.

March 5th.—Had sharp fever and severe abdominal pain for some days, during which she was kept under the influence of morphia. There was a fetid discharge from vagina for some days, which was corrected by injections of Condy's fluid properly diluted. Is now well.

March 20th, 1863.—In consultation, I saw a Mahomedan woman in her fifth labour; water has been draining off for some time, and she has had irregular pains in her back for weeks; has taken several doses of ergot since yesterday; os fully dilated; parts cool; head of child felt high up. Recommended an opiate to procure sleep, and afterwards a stimulating enema and ergot if necessary.

March 29th.—I saw the same case with another practitioner; woman was confined on the 25th of a dead full sized female child; placenta has been retained until now; no hæmorrhage; she has had a purgative and ergot which latter had no effect; pulse fair; skin cool. Introduced the hand to extract the placenta, and found a globular tumour of the size of the fist in the posterior and left wall of the uterus. The placenta was adherent, but partially decomposed, and giving out a most offensive smell. It could not be entirely removed, owing to its decomposition, but it was well broken up, and will be easily removed by warm water injections, which were ordered to be frequently used and diluted, Condy's fluid occasionally added. To have opiates and abundance of nourishment.

April 4th.—Had some fever, but was doing well until yesterday afternoon, when she was found collapsed and cold, and almost pulseless; under the use of stimulants she rallied.

I saw her this morning; breathing very short and hurried; pulse 136; tongue dry; no abdominal pain; is said to have had a rigor yesterday; bowels not moved for some days, but urine is passed freely. Ord-red soup every hour, and ammonia and morphia every two hours. Was informed that, owing to some native prejudices, nourishment has never been given, and she soon sank and died.

September 5th, 1864.—A Parsee, æt. twenty-six; was delivered in hospital on March 30th, 1862, and March 22nd, 1863. On both occasions by craniotomy, and on both at the full term of pregnancy. Had previously aborted twice at two and two and a-half months of pregnancy; is now at the end of her seventh month; uterine heart's sounds distinct; the brim of pelvis diminished in its antero-posterior diameter; patient is only four feet two and a-half inches in height; general health good; bowels open.

Sept. 6th.—Tongue white. Pulv. rhei co., ℥j. s.t.

Sept. 7th.—For the purpose of inducing premature labour, at 4 p.m., the flexible tube of a patent enema syringe was introduced within the os; several pounds of cold water were injected, the injection being kept up for ten minutes; at 8 p.m., labour pains came on, and at nine labour was complete. The child, a female, was born with the face to the pubis, and did not breathe for some time after birth.

Sept. 8th.—No complaint.

Sept. 12th.—Mother and child well. Discharged.

April 4th, 1863.—Mohanmedan woman, æt. twenty-two. Second pregnancy. First child seven years of age. Labour commenced three days ago, when liquor amnii was discharged. Right arm presented, and was torn off before admission at 4 p.m.; cord prolapsed; chest of child presenting at brim; os dilated; pains effective; pulse 108; skin tolerably cool; urine drawn off and chloroform given. Delivery was effected in half an hour by evisceration and turning; child male. Placenta not having been expelled in twenty minutes, ℥ss. of tincture of ergot was given, which in ten minutes took effect; uterus contracted well.

April 9th.—Has never had a complaint, and is now discharged.

April 19th, 1863.—At 7 p.m., was called to see, in consultation, an English woman, æt. eighteen, in her second pregnancy. Her first child was born on 11th August last. Yesterday she had some hæmorrhage from the uterus without any known cause. She was kept quiet, and cold applied to vulva, and the bleeding ceased until to-day, when it returned more copiously than yesterday; ice was applied to the abdomen and vulva, which checked it for a time. When I saw her, the vagina was plugged, and there was only a little oozing of blood; pulse good, and patient comfortable; plug not removed. At 11 p.m., flooding returned and expelled the plug; another had been used, but bleeding was going on; removed it and made an examination; many clots in vagina; os could not be reached; a plug of tow was firmly introduced through a speculum; soup and jelly with stimulants administered; as there had not been the slightest pain or uterine action, a current from an electro-magnetic machine was passed through the abdomen, a conductor being placed on each side for ten minutes when uterine action was set up, which continued to be regular. An enema of cold water was given, which produced a copious stool. No bleeding.

4 a.m. (20th).—Has slept for three hours; expresses herself as feeling better and stronger; no hæmorrhage; pulse pretty good; pains have been going on steadily, and get stronger.

7 a.m.—The plug was expelled by a gush of blood; the head was found presenting; the membranes were ruptured; a small seven months' child was born, and the case did well.

May 23rd, 1863.—Patient twenty-six years of age, at the end of her third pregnancy. Labour commenced yesterday morning, and liquor amnii discharged at 5 p.m. yesterday. No foetal sounds; pulse feeble, but not quick; tongue moist; right arm of fœtus protruding from vagina and dark coloured; evisceration performed; the child a male, very easily extracted. Turning would have been performed had the child been alive; placenta came away in ten minutes.

May 26th.—Discharged well.

June 13th, 1863.—3 a.m., a young woman in her fifth pregnancy. In labour since yesterday morning. Pulse and general condition good; foetal sounds not heard; arm protruding from vagina; os uteri so firmly contracted over arm, that with difficulty the tips of two fingers could be introduced, and a leg could not be reached. Perforator used and child eviscerated. Os contracted so firmly round the neck of the child, that there was considerable difficulty in delivering the head. The placenta

was then thrown off at once, and uterus contracted well. Two hours after delivery had a good deal of flooding, which was checked by the application of cold to the vulva. Recovered well.

August 16th, 1863.—A young European woman at the end of the eighth month of her fourth pregnancy. A fortnight ago had hæmorrhage from the uterus, which was intermittent until this morning, since which time until now (9 p.m.), it has been constant; vagina has been imperfectly plugged, and the upper part of vagina was full of clots; parts relaxed; os large and soft; pelvis roomy; placenta attached to cervix uteri, and over the left half of os; head of fœtus felt behind it; membranes were ruptured with a silver director, and liquor amnii drained away. Pains not increasing in severity, a dose of ergot was given; this having had no effect in twenty minutes, another dose was given, which acted speedily, and in a few minutes a male child was born alive, and apparently mature.

17th.—Mother and infant well. Recovered well.

November 9th, 1863.—Patient admitted to hospital at 8 p.m., in her second labour. In labour for two days. First child said to have been born alive. Right hand of fœtus protruding from vagina and livid; os well dilated but uterus firmly contracted upon the body of the child; antero-posterior diameter of brim of pelvis small; woman exhausted; pulse quiet and feeble. Bladder and rectum having been emptied, an attempt was made to turn but without success, owing to the uterus being so tightly contracted upon fœtus. An attempt was then made to eviscerate, but from the same cause the operation was difficult and tedious; it was at length, accomplished however, a leg brought down, and child extracted with great difficulty. The placenta was soon thrown off, and the uterus contracted well, but the woman sank, and died at half-past two a.m.

November 27th, 1863.—Called to hospital at a quarter to four a.m. to see a case just admitted. Woman in her second labour since yesterday morning; child's right arm protruding and livid; uterus acting powerfully, and shoulder well down in the pelvis; pulse pretty good; bowels moved yesterday; passed urine this morning; catheter could not be introduced. An opening was made into thorax under the right clavicle, and viscera of thorax and abdomen removed. Blunt hook was then fixed upon the lower part of the spine, breach brought down, and delivery effected without much difficulty. Placenta thrown off in a few minutes, and uterus contracted well; child a male. Recovered without interruption.

(To be continued.)

## THE SEWAGE QUESTION.

### SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XXXI.

### NOISOME AND DANGEROUS EFFECTS OF SEWAGE IRRIGATION.

THERE are three classes of effects which render sewage irrigation more or less dangerous to the public. In the first place the emanations are offensive, and are productive of pythogenic diseases. In the second place the percolation of sewage into subsoil water, and thence into springs and wells, is not unlikely to be a source of danger; and in the third place the distribution of undefæcated sewage charged with the ova of intestinal and other entozoa is certain to produce disease in man and animals.

As regards the first point—namely, the offensive and morbid character of sewage emanations, especially in those cases where the undefæcated sewage is distributed in large quantities upon the land, there is abundant evidence. At the Craigintinny meadows, near Edinburgh, the stink is hardly endurable. To use the words of Dr. Ligertwood, who was stationed at the neighbouring cavalry barracks in 1868, "Those fields are certainly a source of nuisance to those living in barracks, from the offensive emanations given off from the open ditches conveying the sewage, and also from injudicious flushing of the fields, for the stench in the barracks is sometimes sickening." At Norwood and at Beddington the Croydon sewage farms are the subjects of constant complaint, and the neighbouring houses and property are greatly damaged in value on account of it. Mr. Creasy, the surgeon of the Orphan Asylum at Beddington, said in his evidence before a recent Parliamentary Committee, that he had known the district ever since it was a sewage farm, and typhoid fever had been in every cottage on the estate; every disease, in fact, assumes a particular type, accompanied by what is called "a sewage tongue." At Aldershot, Banbury, and other places which have been described, the stink of the irrigated ground is a matter of serious complaint; but in most cases these complaints are ignored, or are met with positive denial. "Some people," says the Earl of Essex, "have grumbled at the smell, but I think they are getting tired of doing so, as I take no notice of it." That there are good grounds, however, for such complaints is evident from the remarks of those who paid proper attention to the subject. Messrs. Galton, Simpson, and Blackwell, the referees appointed by the Government in 1856 to consider the question of the main drainage of the metropolis, say in their report that it is a question whether irrigation on a large scale might not occasion danger to the health of the inhabitants of such districts by the pollution of the air of the district, as well as the wells and springs; and Liebig, in his letter to the Lord Mayor of London in January, 1865, said that the fear of producing fever by sewage emanations was not altogether groundless, especially where land was flooded with sewage and converted into a bog. Dr. Copland, in his remarks on the paper of Mr. Fothergill Cook on the "Treatment of Sewage with Lime," stated that in his opinion the effects of sewer gases were never so bad as when sewage was spread out upon the land, and he recommended some process of deodorisation or defæcation before the sewage was thus used. The Select Committee on the Sewage of Towns admit, while advocating the employment of sewage upon the land, that if the power of the soil be overtaxed, and large dressings be applied, there will be injury to wells and to running streams, and they quote Dr. Angus Smith, Mr. Alderman Mechi, Mr. John Chalmers Morton, and Mr. Francis Wyley in proof of it; indeed the instances which have already presented themselves of the malarious effects of sewer gases are sufficient to create alarm, and to show that under some circumstances the proximity of a sewage farm is not altogether devoid of danger. Dr. T. S. Clouston, the medical superintendent of the Cumberland and Westmoreland Asylum, has given an account in the *Medical Times and Gazette* (June 1865) of an outbreak of dysentery among the patients of the asylum, which he says was caused by the effluvia from a field irrigated with sewage. The asylum contained two hundred patients, and before the distribution of the sewage upon the land, the mortality and sickness were greatly below the average of such institutions; but

soon after the sewage had been thus used, severe dysentery appeared among the residents of the asylum. Thirty-one persons were attacked, and of these twenty died; besides which there was much diarrhœa of an ordinary kind. The irrigated field was about three hundred yards from the female ward, in which the greatest number of cases occurred, and it was about three hundred and fifty yards from the corresponding male ward. Both of these wards are upon the ground floor, and Dr. Clouston is of opinion that the effluvia is most concentrated near to the ground. He observed also that the effects were most marked when there was little or no wind and a high barometric pressure. Most of the cases occurred in June, July, and August, when vegetation was most active, and none of them in the winter time. It often happened that there was no marked odour of sewage, notwithstanding that it caused disease; and he was for some time very disinclined to refer the outbreak to the irrigated field, but at last, suspecting the cause, he gave orders for the sewage to be conveyed to a distant part of the farm, and then the dysentery disappeared, and those suffering from it recovered. In the following year, thinking that the sewage might be better applied, he gave directions for a more perfect levelling of the ground, and for its being better trenched and drained; but while this was being done, the sewage again got upon the land, and caused another outbreak of the disease. Dr. Clouston was thus convinced that the sewage emanations were the cause of the dysentery and diarrhœa, as well as the cases of typhoid fever, which occurred in the asylum. Another instance of a like nature occurred at Shaftesbury in the year 1862. The town had recently been drained by a person of no practical knowledge, who carried the sewage into the ditches and ponds of the neighbouring fields. In less than a year, one-eighth of the whole population was attacked with enteric fever, and the results were so serious that Dr. Letheby was requested by the local authorities to inquire into the matter; and he reports that of three thousand five hundred persons who formed the population of the place, four hundred and forty-eight were attacked with the fever. A similar case is recorded by Dr. Letheby as having occurred at Copley village, which lies at the junction of the Hebble brook and the river Calder. The village consists of about one thousand persons, and it was designed as a sort of model village by Mr. Ackroyd, who built it. Near to the village is a plot of meadow land, which was irrigated with the brook water containing the sewage of Halifax; but as typhoid fever presented itself in a serious and unmistakable form, the process was abandoned as a measure of public safety. At the Broadmoor Criminal Lunatic Asylum, it seems to me more than probable that the continually increasing proportions of fever cases from the opening of the asylum in 1863 to the adoption of earth closets in 1869 is attributable to emanations from the land upon which the sewage of the asylum was distributed. Very recently, in the spring of the present year, an outbreak of scarlet fever at Haileybury College, near Hertford, was traced by the medical attendant, Dr. Elin, to the offensive emanations from a garden and field saturated with sewage. All the cases—twenty-three in number—occurred in the dormitories and studies nearest to the garden which received the urine and slops of the establishment, the solid excreta being collected in earth closets. It was noticed that the soil of the garden was sodden with sewage and was very offensive, and another piece of ground of about an acre in extent was therefore taken for irrigation, but this also became offensive,

and then the disease presented itself. But why multiply examples of this kind, when, to use the words of Dr. Buchanan and Mr. J. Nether Radcliffe, in their report "on the systems in use in various northern towns for dealing with excrement, the propagation of certain epidemic diseases, especially cholera, enteric fever, and diarrhoea among communities, as the result of excremental pollution of air and water, is one of the best established facts of sanitary medicine." The chief object, indeed, of sanitary practice during the last fifty years has been to prevent the infection of air with excremental effluvia, and the most notable fact in the present century has been the recognition by Dr. Murchison of the true cause of pythogenic, enteric, or typhoid fever in the poison contained in sewage emanations. It is, however, not alone on account of the specific or special morbid action of such gases that sewage is dangerous. It is also dangerous because of the damp and sodden condition of the soil which receives it. Everywhere the experience of medical practice has demonstrated the unhealthy character of a district saturated with mixture containing organic matters. The fens of Lincolnshire, the rice fields of China, the sunderbunds of India, and the irrigated grounds of Italy and Southern Europe, afford abundant evidence of the malarious influences of such soils. It is a matter of grave doubt whether the Campagna of Rome, which was once the favourite locality for the luxurious villas of the Roman nobility has not derived its unhealthiness from the saturation of the soil with the filthy water of the Tiber.

Again, the researches of Dr. Buchanan and others into the effects of drainage on the prevalence of phthisis, have shown beyond all question that a dry atmosphere is less provocative of this disease than a wet one, and if this be so it is inevitable that the saturation of ground with sewage, and the raising of the subsoil water, must necessarily render the atmosphere more humid than it otherwise would be, and thus create a consumptive influence. Besides which, if the doctrines of Professor Von Pettenkofer, of Munich, be correct, as they certainly seem to be, that fluctuation in the level of ground water charged with sewage is the most active agent of fever and cholera, the consequences of irrigation may be most serious.

In addition to all this, there is the danger of polluting springs and wells to such a degree, as that the water becomes positive unwholesome, and unfit for human consumption. This is the case at Beddington, where all the wells are seriously and dangerously polluted, and it not unfrequently happens that the effluent water from irrigated ground produces illness in cattle that drink it. Even water-cresses grown in such water have caused diarrhoea in the human subject.

## Hospital Reports.

KING'S COLLEGE HOSPITAL.  
SATURDAY, NOVEMBER 11TH, 1871.

*Enchondroma-enucleation.—Hæmorrhoids (Operation with the use of the Clamp).*

By HENRY SMITH, Esq., Surgeon to the Hospital.

THE case of enchondroma, Mr. Smith said, was similar to the case which was lately reported in the MEDICAL

CIRCULAR, inasmuch as it was difficult before making an incision accurately to define the connections of the tumour, situated as it was immediately over the metacarpo-phalangeal joint of the right ring finger. On making the incision however, it was found to be possible to remove the tumour and save the extensor tendon—points of importance, as the woman was a seamstress. Its contiguity to the joint however led him to suppose that an amount of inflammatory action would be set up, which might terminate in an ankylosed joint, although even with such an unfavourable result, it was far better than losing the finger altogether. The tumour was shown to the class, and the characteristics pointed out.

Mr. Smith then drew the attention of the class to a woman suffering from hæmorrhoids, and stated that many hundreds of cases of a similar character had been successfully treated by him, both in hospital and private practice, by the use of the clamp. Secondary hæmorrhage by this operation never occurred; nor in his own practice had he met with failure, though some few cases had happened he believed to other practitioners. Mr. Smith also observed on the Catholic spirit which prevailed among the surgeons of the hospital. Every operation was performed in that theatre as coming within the legitimate domain of the art, and although his clamp might be regarded by some as rather belonging to a specialty, he was content to regard it as a simple addition to the armamentarium of surgery. It had been asserted that patients who submitted themselves to this operation were frequently kept on the table an hour, he would appeal to those who had seen the operation if such were the case; and those who had not seen the operation before, he would patiently await their verdict. The operation had also been called "heroic," as the patient, it was stated, got burnt, but from the extreme care taken in applying the cantery—the width of the clamp which protected the parts, and the whole of the under-surface being lined with a non-conducting material (ivory)—such a *contretemps* was impossible, and could exist only in imaginative minds.

Mr. Smith then proceeded to perform the operation in the usual way. There were three separate tumours, and the time occupied in snipping them open and applying the clamp—cutting them off—cauterising each, and dressing the parts, occupied exactly eight minutes.

Mr. Smith operated a short time previously on a case, in which he said many surgeons would have formerly hesitated to do so, inasmuch as the tumour was of very large size; but by the aid of the clamp all danger had disappeared, provided always the cantery was at a black heat, and the method of applying the clamp was strictly observed. He (Mr. Smith) was never afraid of using his own clamps, as they had all been previously tested by him; but, as the class had noticed, he had, prior to using the clamps belonging to the hospital, ascertained for himself, by placing a piece of gutta percha membrane between the edges of the clamp and then closing them, that they were in perfect and close apposition; as, if such were not the case, there was the danger of bleeding recurring; indeed, it might be said that he (Mr. Smith), without being the originator of the clamp, had so modified and improved it as to render it an instrument of perfect safety. Mr. Smith added that he thought greater praise had been awarded to him in reference to the clamp than he was fairly entitled to. He really was not the originator. He had simply modified and improved the instrument. Another case, in which the tumour was as big as a walnut, and had blood-vessels as large as the radial artery, was removed with perfect safety; but in such formidable cases as these, he (Mr. Smith) considered a suppository a careful and safe adjuvant. "Two points," he said, "you should always bear in mind—viz., to open the tumour at the junction of the skin and mucous membrane; and, 2nd, to loosen the clamp after the application of the cantery, in order to ascertain that all hæmorrhage had been completely arrested."

*Lithotomy.*

By ROYES BELL, Esq., Assistant-Surgeon to the Hospital.

Mr. Bell's case of Lithotomy was interesting on account of the age (72) of the patient, for, as he pointed out to the class, the great and unusual pain the man was suffering necessitated *cutting* for rather than crushing the stone, and in this view he was supported by Mr. Henry Smith.

The lateral operation was performed in the usual manner; and, contrary to all that had been anticipated, the stone was with great difficulty found, was extremely small, phosphatic, and was crushed in the forceps. A careful examination was made, to ascertain that all the *débris* was removed, and the patient was carried to bed.

Mr. Bell then contrasted the small size of the stone and the extreme irritation and suffering of the patient, and said that, although the prognosis was somewhat unfavourable on account of the advanced age of the patient, still, the source of irritation being removed, he hoped for a favourable issue.

## ST. GEORGE'S HOSPITAL.

*Results of Vaccination in last year's Epidemic.*

We have already (MEDICAL PRESS, November 15) given the principal facts on this subject. We have therefore to add Dr. Richard Wilson's conclusions from his paper in the Reports.

Before given an analysis of the cases that were vaccinated, he thinks it well to describe what is meant by the expression a "good" and "bad" mark, which he frequently uses.

"By good cicatrices I mean those that vary in size from that of a threepenny-piece to a shilling; varying also in shape, some being oval, others round, others having several radiations from the edges. They usually have a dull-white appearance, with a well-defined margin, and on the floor of the cicatrix numerous small black specks or indentations ought to be observed, these being due to the ulceration of the rete mucosum, exactly similar to the smallpox mark; it is also said that a good cicatrix ought to be seen at a distance of several yards.

"Bad cicatrices must be considered to be useless as regards the protection they give from small-pox. These, again, may vary in size; but they are usually smooth and shining on the surface, without any well-defined margin, and without any indentations, sometimes being so slight that they can only be recognised as vaccination marks by the position they have on the arm.

"Up to the 3rd day of February, 225 patients were vaccinated, varying from three weeks to sixty-three years of age.

"Of this number, 5 were vaccinated for the first time, and all were successful.

"Of 89 who had 'good marks,' 58 were successful.

"Of 56 who had 'bad marks,' 44 were successful.

"Of 31 vaccinated twice, 13 were successful.

"Of 18 who showed no marks, but were said to have been vaccinated, 12 were successful.

"Of 26 who had had smallpox, 21 were successful.

"I think that it is necessary to note, that the older a person is, the more likely is it that the re-vaccination will be successful. For instance, out of those cases which I vaccinated, taking those with good and bad marks only, including those whose ages ranged from infancy up to the 21st year, 49 were vaccinated.

"Out of 29 of those who had good marks, 9 were successful.

"Out of 20 who had bad marks, 13 were successful.

"Including those whose ages ranged from the 21st to the 42nd year, 83 were vaccinated.

"Out of 51 of those who had good marks, 41 were successful.

"Out of 32 who had bad marks, 31 were successful.

"Taking those whose ages ranged from the 42nd to the 63rd year, 12 were vaccinated.

"Out of 9 of those who had good marks, 6 were successful, whilst 4 who had bad marks were all successful."

## MEDICAL SOCIETY OF LONDON.

MONDAY, OCTOBER 20TH.

DR. PROSSER JAMES read a paper on

OZÆNA,

of which the following is an abstract.

The author alluded to the intractability of the complaint and the almost hopelessness with which it is too often regarded by writers and practitioners, and intimated that care in diagnosis and perseverance in treatment may obtain more successful results. It should be our aim in every case to trace the origin of the ailment, and so reduce it to a mere symptom, though this is so difficult, that most authorities speak of idiopathic ozæna as a disease, and even with all the improvements as yet effected in rhinoscopy, there are undoubtedly cases in which we cannot demonstrate the actual lesion. These, however, he believed, will be gradually reduced in number. The simplest form of ozæna, is that commonly spoken of as catarrhal. It is the result of chronic coryza, in fact, it is coryza with fetor superadded. The patient has suffered from colds for a long time. These became more and more chronic, till at last a discharge remained altogether, and this at length became offensive. Rhinoscopy generally shows that the pituitary membrane is hypertrophied. Sometimes erosions or ulcerations are also brought into view. In protracted cases the membrane may be atrophied, and these are much more obstinate. This kind of ozæna mostly affects strumous patients, and constitutional treatment should therefore be employed in addition to local measures. With cod liver oil and iodide of iron, there is often rapid improvement under the same applications that have previously proved inert. A similar condition to that already described, is common in syphilitic disease of the nose. Indeed, ozæna so frequently occurs in syphilis, that on asking a gentleman the other day what he thought of ozæna, he replied, "It is a symptom of syphilis." This, however, is certainly too narrow a view. In syphilitic ozæna of this kind, it is probably the diseased condition of the mucous membrane that gives rise to the discharge, which is offensive from an early period. In catarrhal ozæna, perhaps the chronic coryza gives rise to the hypertrophy. At any rate the fetor is later in making its appearance. It is much more common for syphilitic cases to give rise to ulceration, and this in fact has almost always commenced before the fetor is complained of. At this stage, the disease must not be neglected, for although now confined to the mucous membrane, it may even in secondary syphilis extend deeper, and involve both the cartilages and the bones. Then the fetor is sure to be aggravated. But it is in tertiary syphilis that the graver lesions mostly occur. In these cases the deeper tissues may be invaded before the mucous membrane. A patient may seek relief from distressing ozæna amongst other prominent symptoms, and yet the most careful rhinoscopy may only reveal the darker, dusky colour of the mucous membrane with here and there erosions. In persons of a strumous constitution, the destruction will be much more rapid, and it is therefore desirable to prescribe for the scrofula as well as the venereal disease. When erosions or ulcerations can be brought into view by reflected light, they should be treated by its aid locally. Nitrate of silver, sulphate of copper, and other appropriate remedies, may be carefully applied to these spots. But the whole pituitary membrane should also be subjected to other agents. The ozæna that occurs in children in connection with inherited syphilis, is often difficult to treat, and the investigation of its pathology is attended with peculiar difficulties. Clinically the chief point is to treat the inherited syphilis, and to bear in mind that the child may be also scrofulous. Rhinoscopically thickening of the membrane is most common. It has been remarked, that syphilis may attack the deeper

tissues first or may extend to them. The former is more common in tertiary disease, and may begin as a gummatous periostitis, going on perhaps to caries and necrosis of the bones and cartilages which exfoliate and give rise to great and characteristic disfigurement. The disease may continue its ravages until the unfortunate patient succumbs to intra-cranial mischief. Acute syphilitic periostitis is a very painful disease. The patient's sufferings are exacerbated by warmth. Hence the leading symptom is intense pain in the forehead and head, worse at night, *i.e.*, when warm in bed. During the exfoliation of pieces of bone, the *ozæna* is most offensive. Some people have attributed this exfoliation to the abuse of mercury, but it may occur when we have reason to believe that drug has not been used, and it therefore seems just to speak of it as one of the manifestations of syphilis, although no doubt it might be aggravated by the injudicious use of the mineral. Besides it is desirable not to forget that caries may occur from other causes than syphilis, for example, mechanical injury. Sometimes the rhinoscope reveals very little to us, and yet the *ozæna* is all the while dependant on diseased bone, which cannot be brought within the range of vision. The prognosis therefore in persons with a syphilitic taint, should be guarded.

Amongst other causes of *ozæna*, mechanical injury, already incidentally alluded to, should be inquired about. Then the presence of foreign bodies is far more common than is generally supposed, especially in children. Sometimes beads, bits of pencil and other bodies are put up the nostrils by children, and remain for weeks, or months, in a few cases for years. They are quite forgotten, and the *ozæna* persists until they are discovered by the rhinoscope and extracted. Those singular formations, nasal calculi, may also be mentioned. Again, *ozæna* may be named as one of the sequelæ of the exanthemata. Abscess may occur in these diseases, and the septum may be destroyed. In strumous children, the bones or cartilages may suffer after these diseases. There are some other causes of which time prevents the consideration, but the author could not lose the opportunity of mentioning the naso-palatine glandular disease described by his friend and colleague, the President of the Society, in the 1st vol. of the *London Hospital Reports*. *Treatment*.—Some points in treatment have already been incidentally mentioned. In every case local measures should be resorted to, and in the great majority constitutional remedies are indispensable. The first point is to clear away the discharges. Until this is accomplished, the diagnosis itself cannot be properly made. What can the most skillful use of the rhinoscope show on a surface covered with discharge or crusts? The use of the nasal douche and the syringe is then the first measure. This will probably have to be continued assiduously. At first common salt, chlorate of potash, carbonate of soda, or other saline, should be used in the proportion of a teaspoonful to a pint or a quart of tepid water. Other substances had also been used by the author, and amongst them chloride of aluminum. This gave fair results, but the best remedy was a permanganate. The comfort this gives to patients is remarkable, and under its persistent use, the membrane assumes a healthy appearance. It at once removes the fetor in many cases, and this is all in all to the patient. A weak solution may be employed at first, gradually increasing it until it produces a little smarting, for it should not be forgotten, that this substance is a powerful caustic, one of the best and safest we can employ. Ulcerations and erosions may be touched with a strong solution or with a paste, and the whole membrane thoroughly and frequently washed with a weaker solution by means of the nasal douche, the atomiser, and camel-hair brushes. Mercurial lotions are used by some, but are not so effectual as permanganates, and the risk of absorption, after the recent case of a far more justifiable resort to the mineral, cannot be overlooked. Various powders by insufflation are sometimes effectual, though this mode of medication has serious drawbacks. Inhalation of vapours, especially that of iodine, is often of great value. Of course, small abscesses are to be opened, pieces of exfoliated bone removed, and other ordinary indications carried out. With regard to constitutional treatment, scrofula has already been mentioned. Anæmia and any cachexia may be present, and if so is of the greatest importance. Then as to syphilis. It must always be treated through the system. Some would use mercury for syphilitic *ozæna*, but the author does not employ it. Sir B. Brodie thought it hastened the separation of dead bone. Mr. Henry Lee had mentioned to the author some cases that benefited by calomel baths. The author would rather iodide than salivate. He gave iodide of potassium in large doses. The dose is to

be measured by its effect on the disease, and the ability of the patient to bear it. Although iodide of potassium is mentioned as the constitutional remedy, because it is the most common form of administering iodine, one object of this paper, was to bring before the Society the value of other salts of the metalloïd. The author had obtained important results in syphilitic diseases of the throat, nose and mouth, from other iodine salts. It is clearly not the potash which cures syphilis, and feeling this, he gave full trial to iodide of sodium. Soda is a constituent of the frame, and is always more easily assimilable than potash. The sodic salt is more pleasant to the taste. Weight for weight it contains more iodine than the potassic salt. It can frequently be taken by patients who cannot tolerate the more commonly used salt. When abroad, the author learned that his experience was corroborated in the Vienna hospitals. Iodide of calcium is also an excellent preparation. It is easily borne by the system, and much more agreeable to take. It may in fact be used as a substitute for table salt. It is really desirable that the profession should recognise that all the salts of iodine are not so unpalatable as the one in common use. A specimen of iodide of calcium was exhibited, which had been prepared for the author by his accomplished friend Mr. Tichborne, of the Dublin Apothecaries' Hall. It was when formed a beautiful crystalline mass, but had been broken up.

An interesting discussion ensued, in which the President, Drs. Semple, Leared, Hughlings Jackson, and Mr. Adams took part.

In reply, Dr. PROSSER JAMES stated, that the nasal douche he had recommended was the same as that mentioned in the discussion, *viz.*, that devised by Dr. Thudichum, that he had spoken of the permanganates as a class, inasmuch as there were important differences between them; that the iodides of sodium and calcium were introduced, because though often used abroad, they had not been much employed in this country, while the iodide of ammonium since being introduced by Dr. Richardson, was frequently used.

Mr. SPENCER WATSON then read a case of

#### SKIN-GRAFTING UNDER CONTINUED IRRIGATION.

Dr. THOROWGOOD then read the following report of the Committee appointed by the Society, to examine Dr. Carpenter's two cases brought forward at the last meeting, and of which the history has already appeared in the *MEDICAL PRESS AND CIRCULAR*.

*Notes of Examination of Dr. Carpenter's "Two Cases of Muscular Anæsthesia" by the Committee appointed by the Medical Society of London, November 17th, 1871.*

*Members Present*.—Dr. B. W. Richardson, F.R.S.; Dr. Lockhart Clarke; Dr. Hughlings Jackson; Dr. Alfred Carpenter.

*Invited*.—Dr. Broadbent; Mr. Brudenell Carter, F.R.C.S.

The following points were fixed upon as the subjects of the report to be made to the Society:—

1. Facts ascertained by inspection.
2. The state of the cutaneous sensibility as shown by points at graduated distances.
3. As shown by electricity with carbon point.
4. The state of muscular contractibility and sensibility to induced (faradaic) and (galvanic) continued currents.
5. The degree of vascular resistance to freezing by ether spray.

In the case of the older sister, æt. twenty-eight, there was found on inspection a very marked lateral curvature of the lower dorsal spine to the left as described by Dr. Carpenter. In walking, the toes were turned in and the feet were thrown forward with a slight jerk and brought suddenly and heavily to the ground. She walked worse with her eyes shut. Says that when the eyes are shut she does not know whether she is in an upright position or not, but when the eyes are closed she could advance and draw back either feet, and know exactly where the feet were. Although she never walked without assistance under ordinary circumstances, she walked a short distance alone, and made one or two steps with eyes shut, she stood for some time the eyes being shut without falling. In these experiments she was assured by the observers, that she should not be allowed to fall. 2. Cutaneous sensibility as tested by points (Dr. L. Clarke), found to be about normal over back, and at various points on leg it was observed during the investigation that red spots quickly appeared where the points had been applied, and the mother stated that bites or stings of insects produced great irritation which lasted many days. 3. Cutaneous sensibility as tested by the induced and

constant current, with carbon points found to be normal (Dr. B. W. Richardson). Interrupted current at 8 points caused gentle sensation on outer side of thigh lost at 6 powers, on inner side 7 powers felt, not at 5. Continuous current of 30 powers not felt on outer part of thigh, and caused burning sensation at inner aspect, similar results from comparative experiments of Dr. Carpenter. Muscular contractility and sensibility tested by faradaic and galvanic electricity with moist sponges. Induced current of full power caused no contractions, and little sensation in muscles of calf or anterior aspect of leg, powerful contractions in muscles of thigh with some pain, but much less than in comparative experiments on observers and on muscles of arms of patients. Continuous current (15 cells), no effect on muscles of calf or front of leg, either on making or breaking contact, burning pain when contact made. Conclusions made by Drs. Richardson and Clarke, great impairment of muscular contractility; no loss of muscular sensibility. This patient resisted powerfully flexion or extension of knee-joint.

#### CASE II.

1. Inspection.—Curvature of spine slighter and lower down; stronger than her sister; required guidance but not much support in walking; gait unsteady and feeble; no jerking of limbs; says that when eyes shut she does not know whether she is in the perpendicular position or not, and would not know whether she were leaning on one side; she walked the length of the room alone, and for about six steps with the eyes closed; stood, for sometime with the eyes shut, the body swaying slightly to and fro; can move legs into any position when eyes shut, and knows exactly where they are. 2. Cutaneous sensibility normal. 4. Muscular contractility much below normal standard, but strong induced currents caused decided contractions in the muscles of the calf and front of the leg. Experiments with ether spray. Case I.—Freezing took place on outer side of leg with 3 strokes in 2½ seconds. In Dr. Carpenter's 6 strokes in 9½ seconds. Patient's forearms, 8 strokes 8 seconds. Patient's thigh, outer side, 11 strokes, 15 seconds, Case II.—Outer side of leg freezing by 3 strokes in 2 seconds 75, repeated several times with similar results. Lower down above outer malleolus, 6 strokes in 10 seconds.

At the conclusion, DR. LOCKHART CLARKE remarked upon the obscurity of these cases, the symptoms were independent of the curvature. The muscular sensibility is not deficient, movements can be made every way with the eyes shut, one toe can be placed upon another, and the finger placed to the nose, the sense of gravity is also good, nothing is dropped when the eyes are shut. Hysteria is not alone a sufficient explanation. He recommended continued current, phosphates and stimulants.

DR. HUGHLINGS JACKSON said that to call these cases of hysteria, was begging the question. He had never seen similar ones, they were not cases of locomotor ataxy or disease of the cerebellum.

DR. SEMPLE thought the term progressive locomotor ataxy a good one.

DR. CHAPMAN thought the malady came under the term paralysis, asking what is hysteria?

The PRESIDENT replied that he considers hysteria to be, "the more or less complete domination of all the emotions and the will by disordered sensations begotten out of undue vasomotor susceptibilities."

DR. CARPENTER considered these cases hereditary, there were various instances in the families of nervous affections and spinal curvatures, but hysteria was not present in these cases, except, perhaps, in a case allied to the fasting girl. These were not cases of locomotor ataxy, there was no pain, no urinary disturbance, he had called them cases of "so called muscular anæsthesia."

DR. RICHARDSON did not like the term "progressive locomotor ataxy." In these two cases he did not make out any mischief in the central spinal system, there was some disturbance of the vascular system, pain is not produced in the muscle itself, skin is generally necessary to pain.

DR. LITTLE said that the connection between spinal curvature and change in the spinal cord was most interesting, there was weakness of the muscle and a twist, not to be explained by occupation or a bad position, the spinal cord was ill-nourished, the peculiarity of the young ladies was, that they did not improve under treatment.

At the conclusion, DR. CARPENTER thanked the Committee and the Society generally for their kindness and attention to these cases, saying that he would continue the treatment with the addition of the continuous current.

WEDNESDAY, DECEMBER 6, 1871.

### THE MASSACRE OF AN AMBULANCE.

OUR various articles on the medical aspects of the late war have excited attention beyond the profession. We are reluctant to make any remarks that may be construed into partiality or to revive controversies we would gladly see buried. But we cannot shut our eyes to the fact that an unusual degree of bitterness has been manifested by medical and scientific men, and that much of this is due to the infringements of the Convention of Geneva that took place. We know that war almost always brutalises those engaged and were prepared to hear of acts of cruelty even in this generation; but it is well that they should be condemned, and those who are responsible for the civilised world.

An authenticated statement of the facts respecting the cold-blooded massacre of the Lyons ambulance was issued several months ago, in the form of a report to the Medical Committee for the Help of the Wounded, presided over by Dr. Christôt, chief surgeon of the Third Lyons Ambulance. Although this report must have been seen by many in Germany it seems to have produced no effect in the way of expressions of sorrow or regret. We call the attention of our German editorial brethren to the sad story, and, as a picture of the horrors of war, we publish Dr. Christôt's report unabridged, a most accomplished friend having placed at our disposal the following translation from the *Lyon Medical*.

GENTLEMEN,—Your committee has charged me to present a detailed report on the attempted massacre of the ambulance of the Saône-et-Loire. The documents received from various quarters by the committee have been deemed insufficient for ascertaining the whole truth, the more so, as in a report addressed to Mr. Verne d'Arlandes, the enemy endeavours to assert that there was no assassination, but a lawful and justifiable self-defence. I could not decline the painful task, not only on account of the many ties which bound me to several of the victims, but also because the ambulance of Dr. Morin and the 3rd Lyons ambulance were on the same field of battle,

Knowing the importance which you attached to this mission, I began at once to collect all such facts as would serve at all to throw any light on this terrible catastrophe. Dr. Bauchacout has been kind enough to furnish me with depositions of the highest importance, being all signed by members of the ambulance of the Saône-et-Loire. I have seen several of the medical staff of this ambulance, amongst others Mr. Cordier, house-surgeon to the hospital; have likewise received several accounts by post. But not feeling yet sufficiently informed, and not willing to neglect any means by which the truth could be brought to light, on the 18th of June, I set out for Dijon, from thence to Hauteville, accompanied by Mr. C. Brun, barrister, of Lyons, and Mr. Chenot, jun., barrister, of Dijon, to whom I owe many thanks for their kind and valuable aid. By these means I could obtain many more details than those I had already transmitted to you whilst your ambulance was still in the Côte-d'Or. Hauteville is a village to the north of Dijon, being about ten kilometres distant from that city. Its strategic position was important, its attitude being the same as that of Talant, from which it is only distant three kilometres by direct line. The possession therefore of this culminating point was of the highest military importance to the attacking army of Dijon.

On the 21st of January, between nine and ten o'clock in the evening, the two first battalions of the 3rd legion of the Saône-et-Loire, took up their positions at Hauteville. The ambulance of Dr. Morin was installed in one of the most spacious houses in the lower end of the village. This house belongs to a Mr. Callais, and is situated on the road which runs through Hauteville from south to north. The plan annexed to the report will dispense with a detailed description of this house and its appendages. One thing only ought to be borne in mind, and that is that its own situation, the position of its exterior yard, and the neighbouring house which faced the south of Mr. Callais's house, all united in making it an impassible point of defence against an attack from south to north as was that of the Prussian army. "At ten o'clock in the evening, in the most complete darkness, the battalion set out from the farm of Changey with the 2nd company (Captain Von Pultzy) to act as vanguard, and marched towards Hauteville. As soon as the vanguard were within a hundred steps of the first houses of the village, it was received by a brisk fire." (Such is the report of General Franceschy, Dôle, 18th March, 1871; and how ridiculous and absurd would any contradiction of the fact be.)

The choice of the house was made more by reason of the total absence of any soldiers in the place, than by its interior arrangements, which, however, proved suitable to Dr. Morin. Callais's house did not shelter a single bayonet—that fact was incontestible. All the depositions made by the members of the ambulance affirm it, and the evidence given by Mr. and Mrs. Callais is so strong that it puts the matter beyond doubt. One sergeant having entered the house, was obliged to quit it by Mr. Morin's request. The exterior court had likewise no troops in it (deposition of Mr. and Mrs. Callais, Messrs. Cordier, Fleury, de Chamvigny, Berland, Alacoque and Baudot). The ambulanciers of the Saône-et-Loire carried no arms whatever. Dr. Morin had several times strictly enjoined his assistants to fulfil to the letter the Geneva Convention, and had himself set the example by giving up the revolver which he usually carried about him to the Captain of his battalion. All wore the cross on the arm.

Two Geneva flags were hoisted on the facade of the house, one at the entrance door of the ground floor, the second on the first story. The flags were of large dimensions, and could be seen at some distance. Military action was to recommence on the following day, and our army too, trusting as before, was preparing to take up the defensive on the morning of the 22nd only. Towards ten o'clock a sharp fire surprised it; and a Prussian regiment advanced towards Hauteville following the road

from south to north. Our Mobiles fell back on the same road answering the enemy's volley by a few shots.

Surprise rendered fighting difficult, and even impossible, so that there really was none. The enemy took possession of the village which could not defend itself. The Prussians entered Hauteville, and our soldiers unable to fight against superior force, quitted the village, and a general flight ensued. Such is the truth on the taking of Hauteville, which the Prussian report, with its usual propensity to exaggeration, has transformed into a brilliant feat of arms. On this matter, too, all evidence coincided.

There was no fighting. One small fact, which, however, has its importance, will tend to prove it. All the southern facades of the houses in Hauteville were pierced through by the Prussian bullets, whilst the northern, which received the fire of the French, only show signs of a few projectiles; the traces of that unequal contest are still very visible.

It was also about ten o'clock that ten or twelve Prussian soldiers burst into the ambulance, of which the members were then in consultation as to what they should do. Some advised an immediate departure; others were opposed to it, declaring that duty bound them to remain at Hauteville, and that the buckler of the Geneva Convention would shield them from any possible atrocities. However all indecision was quelled when their attendance was required to a Mobile who was shot in the face, and to a child of fifteen (Eugenie Picamelot) who was mortally wounded. A Prussian bullet had passed through her chest, and the shot had evidently been fired very near, as it had only struck the unhappy child after passing through a thick door frame.

This first and innocent victim of barbarous aggression was lying in a recess of the large room where the members of the ambulance were then assembled. It was during the dressing of that wound that soldiers of the 61st Pomeranian Regiment (and not the 21st) burst into the house, notwithstanding the most energetic protestations of Dr. Morin, who showed the cross on his armet and the Geneva flag, crying, "Feld-lazareth, feld-lazareth! Ambulance, ambulance!" "Charognes capout!" said the savages with an expression of incredulity and disdain. All the answer that our unfortunate chief Dr. Morin got was three thrusts of the bayonet. He fell; but, getting up immediately, he again repeated, "Feld-lazareth, feld-lazareth!" It was at this moment a bullet was fired which put an end to his life. It was then our turn to be attacked. They knocked us all down with the butt-end of their guns; those who were at all refractory receiving revolver shots. When my turn came I dropped down, and thus escaped being touched. Like all the others, I feigned death; but a soldier having crushed my fingers, I could not repress a movement. Seeing that I was not dead, they made me get up, and four bayonets were levelled at me. There was in the room a Prussian sergeant-major, who asked me whether I was not a sergeant-major. On my answering in the affirmative, they let me go without doing me any more harm. Milliat was dragged out of the room. He was made to turn his back two steps outside the door, when two shots were fired, and he fell down dead. Then it was Fleury's turn to be dragged outside, and I heard two shots fired and he fell; but in a few minutes he got up again, and I heard him trying to run. They shot again. I afterwards learnt that he was only wounded. Baudot only returned in two days time to Dijon to Dr. Chanat, honorary professor of the medical school, where Morin had been received with the utmost hospitality. "We had feared," said Dr. Chanat to me, "that the brave youth would have fallen a victim to his attachment for his chief. Great therefore was our joy when we saw him appear. He was wounded, and had his head bandaged. We could not restrain our tears at seeing his safe escape from the massacre."

The details which my obliging fellow-member gave me confirm all that is written in this report.

The following deposition is another sad proof of this terrible event. It is given by Mr. Fleury, medical student

and infirmary-major in the 2nd battalion of the 3rd legion of Saône-et-Loire:—

"Remaining the last on my feet, I did not fall till I had received two blows on my head with the butt-end of their muskets and two bayonet thrusts in the left side, one of which only grazed my ribs. I lay bathed in my own blood and that of my comrades, who were all stretched on the ground, whilst the enemy proceeded to break open two cases of medicines and wound-dressings, all marked with the Geneva cross.

"After deliberating for a few minutes, the Prussians made one of us get up (I think it was Baudot, the officer in charge of the baggage), and dragged him outside. Then came my turn. When outside the door, I found myself facing a platoon of about twenty men in a line. I understood and wanted to go in again; but all had been foreseen, bayonets were behind me as well as before me. They made me a sign to advance. I did so without hesitation, and stopped at five steps distant from them with my arms crossed. I heard a report of fire-arms, and felt my left shoulder, near the neck, struck by a ball. Fortunately this second wound was not mortal. Thinking it wiser to feign death, I fell to the ground. In a few minutes I felt myself pulled by the leg, and, fearing to be finished off by bayonet thrusts, I got up, preferring to receive a shot which would at once put an end to my life. Then, suddenly changing my mind, with one bound I sprang into the yard. Two balls went whistling after me—one struck my cheek, the other only pierced my hat. That did not stop me from clearing the hedge which bounded the yard, and to reaching the gardens, from where I issued after scaling the walls. Then I crossed the vineries, and after two hours' painful march I reached Pouilly, then occupied by the French."

The horror of these details must not prevent my citing you the deposition of Mr. John Morin, of the infirmary. It is but another sad proof added to the preceding ones.

"I was standing near the door, when I received a blow which felled me to the ground. At the same time I heard the cries of my comrades, but the wretches drowned their voices by their inhuman shouts. When all had fallen, they came back to me, and brutally forced me to rise. In vain I besought those monsters to leave me the little life I had and to take me prisoner. Their answer were two more blows, which again felled me to the ground, and I then felt streams of blood gush from my mouth and nose. My head was cut from the forehead to the eyes, and as I was once more endeavouring to rise, another shot was fired my way. It missed me however, but struck Mr. Morin in the heart, and he fell down dead at my feet."

This sanguinary deed completed, they ate and drank in that same house. Callais' house was then given over to pillage. The soldiers penetrated into all the apartments, even into a kind of cellar, whither Mrs. Callais had dragged a man of the infirmary, in the hopes of saving him from the assassins. The unfortunate man was found, and brutally carried outside.

"I alone managed to escape from the massacre," writes M. Alacoque. "Seeing two women rushing down into a cellar, I followed them. In about five minutes' time the Prussians, thinking they had massacred all the ambulance, visited all the house. Five of them prepared to shoot me, pronouncing with rage the words 'revolvers, chassepots.' By dint of prayer and beseeching, they at last consented to make me prisoner. I could hardly stand up. Three of the Prussians helped me up the stairs, and forced me to cross the room which had just been the scene of the horrible carnage. I cannot describe to you the terrible impression which the sight of my friends bathed in their own blood made on me. I thought they were all dead. I now conclude by affirming most positively that no provocation, no discharge of fire-arms, was made from our ambulance, and no injury of any kind on our part. Nothing can therefore palliate the horror of the massacre of the ambulance at Hautville, committed against all rules of the Geneva Convention." (Deposition of M. Alacoque.)

A servant of Callais' house, a child of 17 years, was taken prisoner, and, notwithstanding the most active steps being taken, no intelligence has been received of him. On the 18th of June, the day of our inquest, they were still without any news of his whereabouts.

This scene of butchery had occupied about half an hour, at the end of which the Prussians quitted the room, having first taken the precaution of placing a sentinel at the door. The assassination had been committed amidst frantic hurrahs!

Madame Callais then came in. She found Morin's corpse lying near the clock; one of the infirmary was lying near the cupboard, two others were stretched on the ground between the recess and the door. All three were more or less seriously wounded. A fourth was hid behind a bed and made his escape; thanks to some clothes lent him by the master and mistress of the house. "Everyone hid or escaped as best they could," writes M. Berlaud. I managed to glide in between the foot-board of the bed, where the young girl was lying, and the wall of the recess. Only a curtain hid me from sight, and I cannot understand how I contrived to escape their search. From there I could hear the cries of the unhappy victims, and could distinguish the voice of my unfortunate friend Dr. Morin, who, in falling to the ground, branded his murderers with the name of assassins. It is impossible for me to analyse the circumstances of this terrible scene.

All that remains on my mind, is a confused mass of recollections, and a horrible smell of powder and blood. Neither could I tell you whether there was a chief among them. All their helmets were alike, without a sign of distinction on any. The butchery ended, the murderers left the apartment and in a few moments the inhabitants of the house entered to render assistance to the young girl. I left my hiding place and beheld all the victims lying in pools of blood. At the foot of the bed lay Messrs. Champigny and Dheret moaning gently. They had been left for dead. I took farewell of them, thinking never to see them again.

Milliat's corpse was stretched in the yard near the pump belonging to the house. All the canteens of the ambulance had been forced open and emptied, nothing was respected, not even the bandages for the wounded. Mr. and Mrs. Callais sat down by the fire and spent the night with the victims. Some Prussian soldiers, in the presence of an officer, stripped Mr. Morin and his assistants. From one they took a gold watch and a purse. On Mr. Callais observing that these unfortunates belonged to the ambulance and ought to be respected—at least after death, the officer answered: "It is our right, and it will help to enrich the company." The valise belonging to the surgeon-major, and containing all the ambulance funds, was likewise sacked. Having kept our surgeon's accounts, I estimate the sum thus stolen at 1,500 francs. (Deposition of M. Berlaud.)

Mr. Morin's portfolio, evidently forgotten or overlooked by his enemies, was found by Mrs. Callais; it was thrust through with a bayonet. It was whilst he was lying senseless that these wretches sacked him and took all they could find. His shoes were the only things which they could not manage to pull off.

Next to Mr. Callais' residence, in Eugénie Picamotot's house lay an officer at the point of death, the brave commander of the battalions, Braconnier, chief of the 1st battalion of the 3rd legion of the Saône-et-Loire. He, too, was brutally stripped of everything—even his clothes, by the unscrupulous soldiers of Major Von Erekert.

These acts of refined cruelty and cupidity will easily account for the following passage, taken from a report of the General Franceschy. As usual, the German heroism and want of sincerity and honor are shown once more by the most glaring evidence. Towards midnight the affray in that house was terrible. About eight men of the enemy were killed. After this resistance had been

mastered, and the building taken, it was discovered, *after a most minute inspection*, that several of the dead and wounded wore the red cross on the arm; and later on was seen the Geneva flag floating from the roof of the house. In the meantime Major Von Ereckert made his appearance, and immediately had the matter investigated (now we know the nature of this investigation), which resulted in the following declarations: "Firstly. During the contest the corpses had been carried away, and the inhabitants of the place had taken in the wounded, so that it was impossible to ascertain whether two French doctors were among the dead, as also the number of individuals with the red cross on their arm, who had been killed or wounded unawares."

[Surely such a report needs no commentary!]

"Secondly. It is also impossible to ascertain whether the individuals with the red cross had carried arms or made use of them at all. Indeed, it is affirmed, that on the first floor of the house mentioned, and particularly near the spot where the corpses of the two doctors were found, a sharp fight against armed men had taken place, and also that a quantity of discharged fire-arms and ammunition were luckily found." (Report of General Franceschy, Dôle, 18th March.)

We owe, however, one extenuating circumstance to these assassins, and that is: that during our sojourn in Dijon, the French authorities arrested several Prussian spies bearing the insignia of the Geneva cross, and more than once members of the 3rd Lyonese ambulance had picked up on the field of battle cartridge boxes containing the red crosses as well as the ammunition.

But let us go back to that night of agony. "I passed the night," said Mr. Callais to me, "in mortal fright, knowing that a movement, a word, or a groan, would entail worse evils on us. The murderers showed an odious cynicism, watching their unhappy victims with unceasing vigilance. More than ten times did they return to see if some of the young men gave any signs of life; approaching the flame of the candle to their faces, or giving another blow with their guns, or crushing their fingers beneath their heel. Each time they left the room, I found great difficulty in stopping the groans of the poor sufferers. One of them begged of me to give him drink, which I was obliged to refuse for fear of betraying him, as the sentinel could see all that was passing in the room. About two o'clock another soldier came in; finding that one of the attendants of the infirmary was still alive, he pulled out his sword to put an end to him, but probably being too great a coward to do the deed alone, he went out and returned with four of his comrades, who fortunately happening to be rather less inhuman than himself, prevented him from accomplishing his bloody design. Three hours after the massacre a superior officer entered the house, and seeing the people of the house in tears, he asked them the cause of it. They answered by pointing to the poor wounded girl, and the dead bodies of the doctors. "You ought to consider yourselves fortunate, replied the officer, that I have not had you killed with the rest, for wherever I have passed I have killed every one." He also accused us of having fired at his soldiers. On our solemn assurance in the negative, he said, "If you had had any franc-tireurs I should have set fire to the whole village." The soldiers being present, their chief almost praised them for their deeds. Being asked what was to be done with the unfortunates who were lying in death-agony on the floor: "That regards me little said he, now that they are shot, it is no more my affair." However, on the repeated instances of the inhabitants, this soldier of humanity promised to send his doctor to attend on the suffering girl. The latter at last put an end to this heart-rending scene, says Mrs. Callais, by delivering the unhappy victims from the homicidal vigilance of the sentinels; and at half-past eight in the morning the dead bodies of the two doctors were carried to the cemetery. This Prussian doctor was the only individual worthy of the name of *man* among

all those savages, says M. de Champigny; it was he who saved our lives.

Mrs. Callais had hardly finished her deposition, when her husband came in, and his account of it tallies exactly with what we have written.

The debt contracted by the victims towards the Prussian doctor was promptly acquitted, for on the following day (the 22nd) the victorious army of Dijon took prisoner a Prussian ambulance at the farm of Changey. In the ardour of retaliation which the atrocious deed of the preceding day almost justified, the Prussian doctors ran a great risk of their lives. But your 3rd ambulance, under the protection of which the prisoners had placed themselves, was wise enough to avoid the shedding of blood, and a second violation of the Geneva convention. I must bring to your notice the courage and energy evinced under these perilous circumstances by my friend Dr. Bernheim, and which merits praise.

On the 25th of January, whilst the cannon was roaring from St. Apollinaire, I sent Mr. Chambry and a van to Huntville to accompany the parents of Mr. Morin, and aid them in their sad task of exhumation, for the corpses had been buried without coffins; the victims' boots had been pulled off and the pockets of the uniforms emptied and turned inside out. Milliat still had his képi, both wore the Geneva cross. The following are the notes taken down by Mr. Chambry at the time of exhumation: "*A. Morin, Major of the Ambulance of the Saône-et-Loire*: A bullet in the upper part of the abdomen; a sword-cut on the left side of the head; a fracture of the skull caused by a blow of the butt-end of a musket; several bayonet thrusts in the left side; in all six wounds. The limbs of the corpse are shrunk, the fists closed, and the face contracted, as is the case with those who have suffered much before succumbing."

"*Milliat, aide-major of the Ambulance of the Saône-et-Loire*: A bayonet thrust in the right breast; a bullet in the left lumbar region. The outward appearance shows that death must have been immediate." At ten o'clock on the 26th inst., we paid the last funeral obsequies to our unfortunate colleagues. The procession started from the hospital whither the bodies had been brought. The commander of the battalion of Charolles, Dr. Jeannin, surgeon-major of a battalion of the Saône-et-Loire, another doctor from the same battalion, and myself held the corners of the pall. The troops stood in lines along the road where the funeral procession passed. Dr. Favre, delegate of the Society for the Help for the Wounded, and several military ambulances chiefly composed of the friends of the victims, followed the bier. Your 3rd ambulance also assisted at the ceremony; none were missing. Milliat's body was interred in the cemetery, whilst Morin's was taken to the station, from whence it was conveyed to his family. Before separating, I could not help saying a few words of farewell to our colleagues, and at the same time adding an energetic protestation. The day preceding the funeral we had decided to abstain from all passionate appeal, in order not to excite the people's feelings. But on seeing the sad procession, the coffin, and the tears in all eyes, our resolution gave way, and I felt but a poor interpreter of the people's feelings when reading the following farewell speech: "Gentlemen, —I know that death loves silence, and that it seems but ill-advised to speak passionate words when standing by an open grave. But the crime which brings us now together, is of so cowardly and atrocious a nature, that we find it impossible not to protest with our utmost energy; for never have the laws of humanity or the grand and generous principles of the Geneva Convention been more cruelly and unworthily violated and trampled under foot. I therefore loudly protest against this conduct in the name of our society, of which Morin and Milliat were distinguished members; in the name of the large Lyonese family, of which we are the representatives, and which is now weeping for its dead martyrs; and in the name, too, of their friends, who are now standing around the

grave, and whose falling tears testify beyond all speech the bitterness of their loss, and the horror of the assassination. Farewell my friends, your names are spoken throughout the whole of indignant Europe, but nothing can console us for our loss. Farewell, you will always live in our memory and our hearts, as heroes of duty and patriotism."

Now gentlemen, I have finished the task which you imposed on me. I have tried to fulfil it faithfully, speaking the truth only, and avoiding the expression of feelings which are but too natural. The truth is a crushing one to our enemies, who only remained at Hauteville as cowardly assassins; the hypocritical veil which the Prussian report tries to throw over it, rendering it only all the more odious and cynical.

### THE GOVERNMENT AND THE TEA FRAUDS.

As the use of diplomatic speech has been truly described as the concealment of the opinions of ministers, so may diplomacy itself be described as the art of avoiding the duties of administration and government whenever such duties are inconvenient. Councils, Committees, and Governments, give as much thought and consider it as much their business to find out legal or practical corners behind which they may hide whenever they happen to be pursued by importunate reformers. Of course, amid the delightful incomprehensibilities of Acts of Parliament and official regulations, there is seldom any trouble in finding a barricade behind which the besieged administrator may fortify himself.

As it does not suit the present Government to fall out with trade adulterators, or with the shopkeepers who vend a fourpenny mixture of iron filings and caterpillars filth as "Moning" tea at 2s. 8d. a pound, the long tried ingenuity of Government officials is being ransacked to find some sort of an excuse which will pass muster as a reason for allowing this special form of trade roguery to go on.

The *Pharmaceutical Journal* informs us that, at the meeting of the City Commission of Sewers on Tuesday week, a report was presented from the Sanitary Committee on the subject of the seizure of spurious tea, which well illustrates the present defective state of the law in reference to the adulteration of food. It stated that, upon a full consideration of the circumstances of the most recent seizure, the Committee did not think it expedient to take legal proceedings against the offenders,—experience in past cases giving them little encouragement to do so. They were of opinion that the traffic could be stopped only by the officers of Her Majesty's Customs, and that no local sanitary authority, even, if armed with fuller legal powers, would be able to deal with it successfully. They had written to the Secretary of the Board of Customs on the subject, who told them that the officers of that department were not empowered to seize and destroy tea, whether spurious or not, even upon a certificate that it was unfit for human food. They then had an interview with the President of the Board of Trade, who intimated that the Board had no power over the Customs, and referred them to the Lords of the Treasury. They next had a conference with the Chancellor of the Exchequer and Sir Thomas Fremantle, the Chairman of the Board of Customs, but with no better result; both those gentlemen being of opinion that even with qualified inspectors locally appointed, the Customs could not be entrusted with such powers as those suggested, and that such powers if used would have a very injurious effect upon trade, and divert a large amount of business from this country. The Chancellor of the Exchequer considered that nothing further could be done without an express Act of Parliament, and that any application to the Government to introduce such a measure, which probably would not pass, should be made either to the Home Secretary or the Local Government Board. The Com-

mittee concluded by expressing regret that there seemed no means open for adoption likely to put a stop to a trade so injurious to the health of the community. The Report of the Committee was approved and ordered to be printed and circulated among the members of the House of Commons and of the Corporation and of the various sanitary bodies in the Metropolis.

After what we have heard from Mr. Bright as to the perfect legality of trade deceptions, and with the knowledge we possess of the importance of the shopkeepers' vote to Mr. Gladstone, it was hardly necessary for the Commission of Sewers to run the gauntlet of five public offices, in order to ascertain that the present Government will do nothing except discourage and obstruct every effort to enforce commercial morality. We find it hard, however, to believe that the law is really so defective. Would it not be possible to settle the question by prosecuting the sellers of this spurious tea and others, proceeding from the retailer to the merchant, lay our finger on the real culprits who are, no doubt, living like princes, and, mayhap, entertaining officials with appropriate splendour on the strength of their profit of eight hundred per cent.

### SCOTLAND.

#### THE LADY STUDENTS.

THE opinions of counsel have been published as follows:—

*Copy of Certain Additional Queries submitted to the Lord Advocate and Sheriff Fraser on the former Memorial, and their Opinion thereon.*

#### *Queries.*

Whether the Senatus, University Court, University Council, and Chancellor had collectively the power of granting to women the permission to matriculate as students, as they did in 1869, and whether the regulations issued officially (November 12, 1869) are valid as regards such matriculation?

Whether the medical professors are exonerated from obligation to teach in some way or other all matriculated students by the fact that in clause three of the regulations quoted above it is merely stated that they "shall be permitted to have separate classes for women?"

In case such women as are matriculated students of medicine in the University are refused instruction by individual medical Professors, what is their legal mode of redress, and against whom should it be directed?

#### *Opinion.*

We are of opinion that the University Court, in virtue of the power conferred upon it by the 12th section (2) of the Act of 1858, have power after communication with the Senatus, and with the sanction of the Chancellor, and after the University Council have considered the subject, to grant permission to women (as they did in 1869) to matriculate as students, and the resolutions of the Court in that year are valid.

The University Court having statutory powers to "effect" improvements in "the internal arrangements of the University," and it being within their power under this enactment to allow women to be educated at the University, and to take degrees, and the Court having resolved (with the necessary sanction), on 12th November, 1869, that "women shall be admitted to the study of medicine within the University," we are of opinion that this resolution must be carried out in good faith and obeyed by the professors. The third resolution of the University Court, of November, 1869, which "permits" the professors to have separate classes for women, in no way derogates from the resolution of the Court that women "shall be admitted to the study of medicine."

We are of opinion that the University Court can compel by action the medical professors to obey the resolutions of November, 1869, by holding separate classes for the education of women. With respect to the title of the women, we think that those of them who have matriculated and passed the preliminary examination have a title, and may enforce their rights by action. The proper form of action is, we think, a declarator against the professors refusing to obey the resolution of the University Court, with petitory conclusions to the effect that they should be ordained to hold separate classes for the instruction of the pursuers, they receiving their due remuneration.—The opinion of

(Signed)

G. YOUNG.

PATRICK FRASER.

Edinburgh, 13th November, 1871.

## ST. ANDREWS UNIVERSITY COUNCIL.

THE half-yearly meeting of the St. Andrews University Council was held in the University Hall last Thursday. Dr. George Lees presented a report, agreeing in the main with those of the Council meetings of Edinburgh, Glasgow, and Aberdeen, at which the suggestion has been made that a Royal Commission would be required to adjust questions connected with the universities, in reference more particularly to curricula or systems of studies suited to the capabilities and prospects of young men preparing for the varied pursuits of practical life. A Royal Commission, the committee believes, would be the best and speediest way of settling all questions now agitating the University Councils of all the four Universities. The committee respectfully suggest that the University Court of St. Andrews following the example of that of Edinburgh, should give greater publicity to their proceedings, either by making half-yearly statements to the Council of what they have done, or sending an extract of their proceedings to the newspapers, as is the practice in the Universities of Edinburgh and Aberdeen. The report was adopted.

ROYAL MEDICAL SOCIETY OF EDINBURGH.—The following gentlemen have been elected Presidents of the Royal Medical Society:—E. Willis Way, M.B., &c., Adelaide, South Australia; Lewis Shapter, B.A., Cantab., Exeter; Henry C. Martin, M.B., &c., Surrey; Arthur J. M. Bentley, M.B., &c., Devonshire.

DUNDEE.—Sir David Baxter, Bart., has intimated his intention of erecting a convalescent hospital in connection with the Dundee Infirmary, to contain from fifty to sixty beds, and so endowed as to defray the requisite expenses.

## Notes on Current Topics.

## Jenner Memorial.

At Berkeley, in Gloucestershire, where Jenner was born, lived, and died, stands a noble old church, in which it is proposed to erect a window to the memory of the man who has done so much for his fellows. The committee list is headed with the names of three earls, and as £500 is the modest sum asked to complete the design, we should think and hope there will be no difficulty in the way of those who have undertaken the carrying out of this graceful act.

## Poisonous Disinfectants.

OWING to the prevalence of small-pox in Wolverhampton, as reported in this Journal a fortnight since, disinfectants have been used in the town to an enormous

extent. In some of the workshops, men have become exceedingly sick and unable to follow their occupations, whilst not a few domestic animals have succumbed to the disinfecting powder used. The subject deserves investigation.

## Bromides in Epilepsy.

SOMETIME ago Dr. Lutz stated in the *Berliner Klinische Wochenschrift*, that he had employed bromide of potassium in ten cases of epilepsy with good results. In three patients the attacks were entirely suspended for six months, in the remainder they occurred in much greater intervals. Lutz began with 1-3 grs. *pro die*, and increased gradually up to 10-20 grs. daily. The author found especially good results from the combination of the bromide of potassium with the bromide ammonium. This seems to him a fresh proof that the bromine is the active principle. Also in nervous headache the bromide did good service. One case of enuresis nocturna was promptly cured.

The *Medical Cosmos* says "the bromides of sodium and iron may be often combined or substituted with advantage in this and other disorders."

## Vaccine Matter Preserved for Years.

DR. D. B. HILLIS, of Keokuk, Iowa, writes to the editor of *Chicago Pharmacist*, as to the efficiency of the plan of preserving vaccine virus between layers of the red rubber used by dentists, "for several years past I have used no new matter, but have, for the sake of experiment, drawn from the stock originally put up as described. I have always found it effective, though no care whatever has been taken as regards temperature. Last week I successfully vaccinated a patient from a crust which had been lying about my office in rubber for twenty-seven months."

## Chlorine Water.

A SIMPLE method of preparing chlorine water is described by Mr. R. Rother "by pouring into a quart bottle four fluid ounces of solution of chlorinated soda previously mixed with twelve fluid ounces of water, and then diluted chlorhydric acid by gradual addition until, firstly the carbon dioxide has been liberated and expelled, and secondly, the available chlorine has all been set free and absorbed by the water, aided by frequent agitation. This product seems to be more permanent than the official article, as it retains the powerful odour of chlorine for a considerable time even in bottles partially filled, if they are kept cool and excluded from the light."

## Inoculation as a Preventive of Small-pox.

DR. E. J. BEALL (*Med. Archives*), writes that in 1866, in Brazos Co., Texas: "I had to treat eighteen or twenty cases of small-pox. There were no cases nearer than Millican, twenty miles distant. A man or two went down—a *calico* dress was bought and taken on the place, and the wife of the man who bought the dress, twelve days after its purchase, was taken with small-pox, and the number of cases mentioned occurred. The woman who was first seized had not been off the place for twelve months. Indisputably the cotton dress was the means of introduction. I subsequently learned that a case existed

in the rear of the store in which the negro bought the dress. No vaccine virus being obtainable, in the face of a State statute I inoculated, after a time, from the first case, isolated the farm, and one death was the mortality in the whole number of cases. I am satisfied with the inoculation, &c., in the cases."

The Editor of the *Medical Cosmos* remarks upon this statement as follows:—"In our student days we read an account of some experiments which made a deep impression upon us. It was to the effect that a German, by the name of Lichstentein, we believe, had taken the pus from a tartar emetic pustule and inserted it into the arms of divers persons, children and adults of both sexes, with the result of causing a pustule having similar anatomical characteristics as the true vaccine pustule, and what is still more wonderful, affording the same protection against small-pox as vaccination in the regular way. Now, this may be fact or mere fancy, but in lieu of the usual protection under such circumstances as the above, it would be right to give the people the benefit of the doubt and practically test the correctness of such observations."

### Chloro-Acetic Acid in Fibrous Growths, Etc.

DR. W. H. ATKINSON says (*Dental Cosmos*), this agent "has a strong affinity for dead connective tissue, epithelial scales, indurations, warts, and fibrous growths. For correcting unhealthy and brawny faces, for which 'enamels,' 'bloom of youth,' &c., have been resorted to to such an execrable extent, and producing a beautiful skin, these acids, judiciously used, stand unrivalled, dissolving off the old scales, and favouring the growth of a new supply."

### Sham Diploma Practice.

THE almost impossibility of bringing illegitimate practitioners to justice under the powers of the Medical Act has been again illustrated. Last week, a chemist named Lakin was charged at Leicester Town Hall with wilfully and falsely pretending to be a duly qualified medical practitioner. It was given in evidence that the prisoner kept a shop as unlike a chemist's, and as like a surgery as possible. On his door-plate he styled himself "Dr." Lakin, and issued a death certificate signed, W. Lakin, M.D. (U.S.)

For the defence, a diploma from "the Eclectic Medical College of Pennsylvania" was produced. Respecting this document,—

Francis William Crick, of Bedford, "eclectic" practitioner, said he was a member of the College of Pennsylvania. That was a College in the United States, having authority to grant diplomas in medicine. Had *not* been in Pennsylvania. There was a board of examiners in this country communicating with them. He was not on that board. Had had correspondence with Dr. Buchanan, and knew his handwriting. The handwriting on the diploma produced he knew was the handwriting of Dr. Buchanan. They could be examined by a board of examiners in this country without going over to Pennsylvania. Had been himself examined by the board in this country. The result of the examination was transmitted to Pennsylvania. (Cross-examined :) There must be a personal examination. The preliminary branch of education he went through was *general English*. He went

through his preliminary education at Bedford. The board of examiners sent to them questions by post, and *they filled them up at home*, and transmitted them to Dr. Payne, of Leeds. They were examined at Leeds in surgery, anatomy, and obstetrics. Witness was under the tuition of a competent preceptor for over three years. *Did not personally know any preceptor*. Never saw the doctors before whom he passed his examination in his life. It was not necessary to be three years under the tuition of a medical preceptor, nor was it necessary for them to go before the medical examiners. He was before the board in Leeds in 1867, but did not know who they were. *Could not tell the justices one question they asked him, either in surgery or botany*. Could not tell them what he paid for his diploma, but it was a considerable sum. Was sure it was more than £10. It was something between £10 and £100.

The magistrates reserved their decision until Friday week.

### Chemical Treatment of Disease.

A BRIEF article in our issue of Sept. 12, seems to have given offence to the gentleman whose views we reported. Dr. C. B. Hall, of Toronto, had published a paper on "Consumption" in the *Canada Lancet* which formed the subject of one of our "Notes on Current Topics." Dr. Hall replies to that note in the new number of our contemporary as follows:—

SIR,—I would not call your attention to the flippant remarks of the 13th September number of the *MEDICAL PRESS AND CIRCULAR* on my paper on "Consumption" published in the *Canada Lancet* a short time ago, if this were not the particular season when medical students are mostly undecided as to the relative importance of different schools in granting degrees in their profession, and to show, from this circumstance, how much are our own country schools in advance of their forefathers. For the former would have given "happy Dr. Hall" credit for a medical practice taught by the first men of Europe for twenty years or more, nor would they have applied the term "faith" as illustrative of that which has been the subject of perfect demonstration. The chemical theory of consumption attempted to be ridiculed is taken from Professor J. Hughes Bennett's work on "Tuberculosis," published in 1853; the use of chemical agents in the treatment of disease generally, and particularly of pneumonia, from Liebig of a little earlier date; the application of fats, as used in the prescription referred to, from the discovery of M. Pelongé, who states that animal oils at an elevated temperature are resolved into their respective acids, and can in this state be brought into the general circulation. My reasons for giving the preference to butter over other fats is fully shown in the October number of your journal. For the further chemical changes in the animal economy, such as starch into sugar, and of its being checked in diabetes, as well as the change of lithic acid by this same chemical process into hippuric acid, I appeal to the distinguished names at the close of my paper,—*viz.*, Lehman, Jones, Garrod, Ure and others. One most important mistake as to the use of fats I wish to correct. "He expects the *good derived* from cod-liver oil will be equalled by any fat properly given." This is not my meaning as I would have it understood. What I do mean to say is, the reason *no good* of any consequence has been derived from cod-liver oil, or any other fat, is owing to its not having been *properly given*, but in such unprepared form as to allow of its combining with the alkalis of the system, and conversion into soap.

C. B. HALL, M.D.

We regret to have annoyed Dr. Hall, and do not think our remarks deserve his anger. They were founded upon a very careful perusal of his paper, which we found very interesting, and did not wish to "ridicule." We did,

however, intend in the fewest words to imply that we had not the faith he appears to have in the power of chemical treatment to cure consumption, diabetes, pneumonia, &c. We are happy to accept his explanation respecting cod-liver oil, and agree with him that one of the elements of success with it is to see that it is properly given.

We were quite familiar with the writings of all the authors cited, but we do not think any one of them would look upon the cure of disease as a matter of "certainty" which seemed to us the gist of Dr. Hall's paper. All we can say is that if he always has that certainty we were justified in calling him "happy." We should ourselves be happy indeed in such a case.

### An Indian Lunatic Asylum.

THE following startling statements from the *Pall Mall Gazette* demand immediate investigation:—

"An Indian paper which has been forwarded to us contains an account in great detail of the treatment of the inmates in the Bhowanipore Lunatic Asylum of the Government, near Calcutta, so shocking that it cannot be passed over in silence. It must be earnestly desired that some part of it, at least, may be disproved. Condensing the narrative, it appears that the asylum consists of a fine hall, standing in well-kept grounds; the hall formerly used for patients being now devoted to the occupation of officers and their families. Around the compound are huts or cells, in which are placed European lunatics. 'These abodes resemble our stabling for horses, containing the usual space so allotted.' Each cell, it is said, has an iron grating before and behind it, and there are grated openings between the cells. The only furniture is an iron bed and bedding, and at night a black blanket is served out; sheets and pillow cases are thought too costly. An hour or so before daylight each patient is unlocked by the Mahomedan keepers, and the patients are marched off, one and all, stark naked, and placed under the heavy waterfall from a large tank. 'Thus refreshed or stunned as the case may be,' they are marched back to their cells, there to put on their clothes. This done, 'half a pint of liquid termed tea, with half an ounce of bread,' is given to each patient; they are then paraded and complete their toilette under the trees, and breakfast on tea and bread-and-butter at 8-30 A.M.; and at 10 A.M. a gong sounded at the front gate announces the approach of the Burrah Sahib, an elegant equipage dashes in, 'a few hasty words are spoken to the assistant-superintendent, and thus ends the daily labour of the highly paid superintendent.' Very many patients from month's end to month's end, it is stated, never hear the doctor's voice. Upon his departure the patients are immediately returned to their night quarters, to fight out as best they can the irksomely long days, without the slightest recreation or amusement. No such thing as a punkah is known there; during hot seasons the heat is described as truly intense, the air being shut out by the dense surrounding plantations and shrubberies and high walls enclosing the patients' cells. The tedious days are succeeded by nights which 'are simply horrible,' many having to battle with rats and vermin of all kinds; mosquitoes and sandflies abound in millions, and having no other seat but the bricked floor, and 'no other bed or bedding but a black rough blanket,' the situation of the European lunatic in his cell at Bhowanipore is described as 'distressing.' The midday meal consists invariably of a small plate of rice and curry and stew; which might suffice, it is said, if the patients were not habitually robbed by their Mahomedan keeper. The hardships especially complained of are, it seems, of comparatively recent growth. A few years ago the centre building was used as the place of daily meals; the hall was lighted up in the evening, and the patients admitted to amuse themselves; a well-furnished library was at the disposal of the inmates; con-

valescents were gathered at divine service on Sunday in the chapel in the general hospital compound, and the friends and relatives of the lunatics were allowed to correspond with them, and encouraged to furnish them with the means of alleviating their affliction. All this, it is alleged, has been changed since the removal of Dr. G. Butler some seven years ago. Not having the means of directly verifying these published statements, we can only give them for what they may be worth, in the hope that they may be thoroughly investigated."

### Royal College of Physicians of London.

A CONCESSION has been made to the licentiates of the College who are henceforth to be allowed the use of the reading-room. This is what we were the first to mention as likely to be granted. There is, however, one more thing to which we invite the attention of the Presidents—the condition of members. On the one hand, the fellows who have a share in the Government seem to monopolise all the honours and they have a reading-room of their own. Now the *Licentiates* are to be admitted to the reading-room hitherto reserved for *Members*, but these last are not to have the privileges of *Fellows*. Now what is to become of members? who, after all, are pure physicians, while licentiates are general practitioners. We think the only course is, to promote a larger number of members to the Fellowship.

### Evolution.

It is not often that a sermon is devoted to the defence of science. The Rev. Geo. Henslow, M.A., Lecturer on Botany at St. Bartholomew's Hospital, has, however, preached on "Genesis and Geology," and in the course of his sermon, just published by Mr. Hardwicke, put forth "a plea for the doctrine of evolution," which we have great pleasure in commending to the attention of our readers. Mr. Henslow maintains with great power that the works of God cannot contradict his word, and that Revelation and Science are therefore as one, nay, more, while science brings to light the hidden treasures of 'physical truth,' her votaries, he tells us, rejoice that each new truth established has, in turn and time, met with a responsive echo from the word of God."

### The Dublin Pathological Society.

THE adjourned meeting of the Pathological Society will assemble on Saturday next for election of Council. We hear that a very large meeting of the members was held last week in the rooms of the University Choral Society to consider the steps to be taken in reference to the constitution of the Council and other essential reforms. We refrain for obvious reasons from recording the proceedings at that meeting, but we are satisfied to know that a feeling has been aroused which can only be met by the complete and much needed rejuvenation of the society. There are many details to which the Society cannot apply itself, and which if they are omitted from the calculation will prejudice the effect of the revolution. We earnestly hope, therefore, that the members will take care that the reconstitution of the Council in whom the regulation of these details will be, shall be thorough, and that progressive, large minded and liberal men shall have a distinct majority in it, over the inevitable admixture of representatives of a narrow and obstructive policy. Nothing will serve the Society so much as freedom of expression and

opinion, and if it is to prosper in the future it must be thoroughly emancipated from the "huggur-muggur" which has hitherto involved its proceedings.

### Chicago College of Pharmacy.

THIS college, which had become one of the most prosperous and important educational bodies in America, has lost its all in the great fire. They have lost their library, museum, apparatus, and the whole stock of their organ, *The Pharmacist*. The value of the above was estimated at £2,000. There was a partial insurance, but unfortunately it was in a Chicago office, and worth little or nothing. We believe there is already a committee appointed in London, which includes the President of the Pharmaceutical Society, the ex-Lord Mayor of London, the President of the Pharmaceutical Conference, and some influential scientific men with the object in view of helping this institution in its hour of need, and when we consider the important bearing such an institution would have upon the Great Western States of America, we have no doubt about the hearty response this appeal will receive in this country.

We have been requested to state that, any contributions from our subscribers in Ireland, such as specimens for the museum, of chemicals, drugs, apparatus and books, will be taken charge of by Mr. C. R. C. Tichborne, of Dublin, and forwarded to their destination in the name of the donors.

### Lunacy in New South Wales.

ACCORDING to the latest lunacy statistics of New South Wales, there is one insane person to every 391 of the population. Of the 1,300 insane nearly two-thirds were males, and about one-fourteenth were of the convict or criminal class.

### Phthisis in Melbourne.

By the last mail we have further statistics in confirmation of our recent remarks as to the prevalence of consumption in some of the antipodal regions hitherto believed to be almost, if not entirely free from this scourge. The figures are as follows:—

"During the four weeks ending the 8th September, 30 deaths (exclusive of those of natives of the colony), took place in the Melbourne Hospital—14, or 47 per cent., of which were accessioned by phthisis—11 of the persons who died of consumption had respectively resided 5, 8, 11, 15, 3, 22, 10, 18, 19, 16, and 14 years in Victoria, or an average of nearly 11 years each; and 3 had arrived in the course of the present year."

### A new Remedy for Leprosy.

THE civil surgeon of Furrcepore, India, Mr. Bose, is reported by the *Homeward Mail* to have discovered a remedy by which he has saved many lives. It is the production of the Kurehii tree, whose seed named Indrajab, is said to possess the extraordinary virtue claimed for it by Mr. Bose.

DR. ALDIS, the district medical officer of the Board of Health, has paid a visit of inspection to the Royal Orthopædic Hospital, and has expressed his entire approval of the new system of ventilation, and other alterations for the improved sanitary condition of the building.

THE opening meeting of the Surgical Society of Ireland will be held at the Royal College of Surgeons on Friday next.

DR. MASSEY has addressed a letter to the *Derby Reporter*, exposing the condition of the tenements of the Derbyshire peasants, which should nerve the great proprietors to immediate action.

DR. THOROWGOOD has been appointed lecturer on *Materia Medica*, at the Middlesex hospital. We congratulate the authorities on having secured such a valuable addition to the staff.

THE Medico-Psychological Association of London will meet this (Wednesday) evening at 32 George street, when Dr. Mardsley will read a paper on the question—"Is Insanity on the Increase?"

IT is announced by the *Medical Times* that the Council of the London College of Surgeons is about to revise and improve their examination for Dental Diplomas. The new examination is to be partly written and partly *viva voce*, and more practical in its character than heretofore.

THE subject of essays for the gold medal of the Dublin Pathological Society next year has been declared by the Council to be "The Diagnosis and Pathology of Injuries of the Thorax, and its Contents." The adjudication will be made in April.

OUR advertising columns last week recorded the presentation of a well-deserved testimonial of regard and esteem to Dr. Morrison, of Newry. Dr. Morrison, for no less than forty years, held the Physiciancy of the Newry Fever Hospital, and his retirement from his official duties has evoked much kind sympathy from the gentry of the neighbourhood.

A CONTEMPORARY states that the Postmaster-General has decided to avail himself of his powers to exclude from circulation through the post-office the pamphlets and bills of the obscene quacks on the ground that they are vile and immoral. It is greatly to be regretted that the newspapers, which give currency to the filthy inuendos of the these swindlers, cannot be dealt with in the same way.

LAST week, an inquest was held at Doncaster upon a young woman who had died from the bite of a cat, which had become mad after a fight with a dog, which had subsequently been killed. The master of the poor girl is also ill, having been bitten in the thumb when removing the infuriated animal. It rarely happens that one hears of a verdict of "death from hydrophobia" from the bite of a cat.

THE next Actonian Prize of The Royal Institution will be awarded in the year 1872 to an essay illustrative of the wisdom and beneficence of the Almighty. The subject is "The Theory of the Evolution of Living Things." The prize fund is two hundred guineas, and it will be awarded as a single prize, or in sums of not less than one hundred guineas each. Competitors must send their essays to the Royal Institution before June 30, 1872. Adjudication will be made by the managers in December, 1872.

THE mortality in Paris has risen ten per cent. during the past week.

A SULPHUR spring has been discovered in the neighbourhood of St. Omer; the water is being submitted to chemical examination to decide its medicinal properties.

A TELEGRAM from India states that a fearful explosion has occurred in the Laboratory at Agra, killing two of the officials and thirty-four natives.

WE are promised Dr. Morgan's new work upon the "Contagious Diseases Acts, Syphilis and Syphilitic Inoculation," free of the press in the course of the present week.

THE Middlesex magistrates have been engaged in considering the charges of Dr. Lankester, one of the county coroners, who, though he has held six inquests less than Mr. Humphreys, has charged £60 more. This fact is accounted for by the frequency with which Dr. Lankester orders a post-mortem examination, which the Clerk of the Peace holds to be an "improper application of public money."—*Observer*.

In the metropolis last week 1,863 deaths were registered, being 179 above the average. The deaths from bronchitis showed a further great increase, the figures for the last three weeks being 180, 257, and 380 respectively. Of the last high number 155 were children under five years of age, and 147 persons over 60.

THE meeting of the Medical Graduates of St. Andrews, took place on Friday and Saturday last. The volume of the *Transactions* was distributed a day before the meeting and contains some interesting contributions. The dinner was celebrated on Saturday evening. On December 1st, a discussion was opened by Dr. Swete, on "Habitual Drunkenness." The anniversary address was delivered by the President, Dr. Day, of Stafford, who also took the chair at the dinner in the evening. Deputy Inspector General Dr. Gordon, C.B., was elected President for the ensuing year.

A SAD story comes from Wakefield of an hospital tent on fire and the loss of three lives. The fire occurred in two tents. One of them was appropriated to the use of small-pox patients, and the other to that of the nurses. There were only three patients in the hospital. A pillow which had been thrown off the bed by a patient during delirium had fallen upon a gas stove, and on attempting to carry it out, the flames from it set fire to both tents. Mrs. Idle, while attempting to remove a little girl, was surrounded by the flames, and when rescued, the child was dead, Mrs. Idle surviving only a few minutes. A young man named Tyas was also so severely burnt that he expired almost immediately.

WE are requested to beg, on the part of the Editor of the "Irish Medical Directory," that gentlemen who have not returned their names, addresses, and qualifications for publication will at once do so. Two circulars have al-

ready been sent to the entire Profession in Ireland, and yet many practitioners have omitted to return their forms. These gentlemen must be informed that that omission will cause their names to appear without any appendage other than their registered qualifications, inasmuch as no details can be taken from other publications, except under the special authority of the persons to whom they refer.

## SPECIAL CORRESPONDENCE.

(FROM OUR SPECIAL CORRESPONDENT.)

ROME, Nov. 23, 1871.

To the London Editor of the MEDICAL PRESS.

THE past and the future of the Eternal City must, my dear *confrère*, interest your readers as well as yourself, and indeed everyone else, whether like you, they have spent some time here or not. More especially the intellectual future of our capital must interest your readers; for among the countries that wish us well we all believe that the sympathy of your powerful country is entirely with our desire to combine progress in science with liberty. But probably in a medical journal, I had better confine myself to matters concerning the profession. I propose to give you a few details respecting medical education, which is just now undergoing many improvements in our ancient university.

The government that entered the breach at the Porta Pia found our medical institutions in a deplorable condition, and has wisely taken them in hand at once, as it is easy to introduce improvements in medical and scientific education, without bringing parties into collision or infringing the domain of conscience.

Everyone agrees that medicine should be taught scientifically and practically. Accordingly, some important appointments have been made: Signor Corradi, the celebrated operator and inventor, who gained the Argenteuil prize for pathological anatomy, has been entrusted with the surgical clinique.

Professor Tommasi-Crudeli has been promoted from his chair at Palermo to the anatomical professorship here. He is a most distinguished man, and has gone through the anatomical courses at Berlin.

The government has also given a chair to Professor Todaro, of Messina, who discovered a tendon in the tricuspid valve, and has made important researches into the nervous system; and has received the rewards of several German academies for his discoveries.

A chair of Histology is erected to be entrusted to Moriggia, of Turin; another new chair is Diseases of Women and Children, to which Dr. Pasquali, of Rome, is appointed; another, Diseases of the Ears, to be held by Dr. de Rossi. Venereal Diseases also obtain a new position, and Sig. Laurenz, of Rome, is the first professor. Lastly, for Ophthalmology, they have appointed the celebrated oculist of Bologna, Sig. Magni.

This shows that if education was behind, an attempt is being made to place it on a broad foundation.

The University opened on the 16th November, and an Inaugural lecture was given by Professor Moriggia, who took for his subject "Physiology in Education."

I speak not of the other faculties at length, though I believe they were behind that of medicine. Nevertheless, in every one of the Faculties, there were some men whose merits were incontestible. The defect was, that more were wanted and this defect you observe, is being remedied.

There were always many foreigners here, and of course many foreign doctors. Germans, English, and Americans are always numerous. Italy, a free country, proud of her liberality allows all full scope for the exercise of their talent.

I wish you, my dear *confrère*, would once more come among us and renew our pleasant conferences,

## MEETING OF THE "CHARITY ORGANISATION COMMITTEE."

DECEMBER 2ND, 1871.

MR. ALSAGER HILL in the Chair.

THE question of "Provident Dispensaries" was discussed at some length,

MR. FAIRLIE CLARKE said that the treatment of patients at dispensaries is only one part of larger questions—that of out-patients of hospitals, which would shortly be considered. It is not desirable that poor people who can pay 10s. 6d. a year for medical advice should get advice gratis. The Westbourne Dispensary was converted recently from a free to a provident dispensary, as was also the Notting-hill Dispensary. The Poor-law Board has recently constructed many free dispensaries, so that it was needless to keep up the free dispensaries system.

DR. HAWKESLEY said that the degrading and improper effect on the public of free medical relief is very noticeable. But there is also the other difficulty of improper people being seen and prescribed for by medical men. The medical officers of hospitals, &c., are overworked in these insinuations for nothing, a most important point.

MR. C. TREVEYLAN said there is a third evil—that "malades imaginaires" are not confined to the rich. London clergy say that many of the poor use no end of drugs, tonics, and cordials. A large proportion of hospital patients are of this character. Although now a hackneyed point, medical charity is doubtless one of the most pauperising parts of London charity. Ordinary charities do not touch many classes; medical charities degrade all. The middle-classes who can pay something should be dealt with on the provident principle. Dr. Llewellyn Davis had said that one of the difficulties lay in the funded properties possessed by some of the dispensaries.

DR. C. R. DRYSDALE said that he had for years been so convinced of the superiority of self-help for the poor, that he had in two annual reports to the committee of the Farringdon Dispensary, Holborn, recommended that the dispensary should be changed into a provident dispensary. Unfortunately, the committee had no experience or knowledge of such institutions, and objected, partly because there was some funded property belonging to the charity, but mainly because they doubtless did not understand the merits of the case. Propaganda was needed, and all committees of dispensaries should be educated by means of pamphlets. All dispensary and hospital medical officers ought to be paid for the work done. It made them more conscientious and more attentive, as well as happier. In Paris all were paid, and London was abominably ill managed in such matters, to the great injury of the poor and the medical profession.

DR. PARKER YOUNG said, with regard to funds, there is no abuse when they are carried over to a benevolent dispensary. The Western General Dispensary had some funds, and he (Dr. P. Young) with a clerical friend got it changed into a provident dispensary. Some of the governors withdrew their subscriptions, but not many, and now there are more patients than before. The class of patients is nearly the same, and about £250 a-year is received from them, or £20 a month. The simplest plan is to convert any present staff as it stands. Exactly the same duties as before are performed by the staff, and more people are attended by them than they please at home.

DR. FORD ANDERSON said the advantages of provident dispensaries are—1st, home visiting; 2nd, the patient becomes attached to his doctor. The advantages to the doctor is that he is paid, and the work paid the more he works. We are at present simply helping the employer to pay his men, and lowering wages to that extent. Difficulties—Many persons are "consultants," and don't visit people at home. This is provided for in the rules by a resident medical officer, and consultation days might take place.

MR. PARKER YOUNG said the resident officer attached to the dispensary would attend out-patients. Midwifery is attended by midwives.

MR. CURGENVEN said that all agree that free dispensaries are beneficial. The Farringdon Dispensary Committee might be well invited to attend a meeting. We should take up the free dispensaries separately.

## Correspondence.

## THE DISCOVERY OF THE CIRCULATION OF THE BLOOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Profession is under considerable obligation to Dr. McKeogh for the trouble he has taken to show that Plato, who lived 395 B.C., was not unacquainted with the fact of there being a circulatory system. Evidently that ancient philosopher, speaking as he did of the source of the rapidly circulating blood (*πηγήν τοῦ περιφερομένου ὀμοειδῶς αἵματος*), and of a state of things in which the rivulets of blood would be in continual movement (*τὰ τῶν φλεβῶν ρεοὶ νάματα*), must have had some knowledge of the circulation. But even he is not the first whose writings reveal such knowledge. The wise man who averred that there was "nothing new under the sun," in his book of Ecclesiastes (xii, 6), speaks not only of the "silver cord," or spinal marrow, nor only of the "golden bowl," with its organ of thought; but he makes mention, also, of "the pitcher at the fountain," and of "the wheel at the cistern." Now, both these last mentioned are remarkable expressions, and deserve far more careful and scientific consideration than, I believe, they have ever yet received. In the Septuagint, the word for "fountain" (*πηγή*) is precisely that which Plato uses to describe the heart; and the additional idea conveyed by the term "pitcher," suffices to show that Solomon was aware of the receptive, as well as of the spending functions of this organ. And if we turn to the other expression, we seem to have the pulmonary circulation pretty clearly indicated also; for not only have we the word "wheel" (*τροχός*) used, but mention is made of a "cistern," or reservoir (*λάκκοῦ*). Indeed, this latter term may draw our attention to a fact which is too much lost sight of now-a-days, namely, that the lungs form the safety-valve to the heart. The heart itself having unyielding walls, cannot hold more than a fixed quantity of blood. Consequently, unless it had some reservoir conveniently near to relieve it of occasional flood-tides, it would be liable to constant impairment, and the circulatory and nutritive systems would speedily become deranged. But in the lungs, whose membranes are (within limits) yielding and elastic, it has such a reservoir, which serves not only to aerate the blood, but, except in cases of extreme stress, to maintain also the proper balance of the circulation, under all the varying circumstances to which man and animals generally are exposed. I do not say that the lungs are the only safety-valve, but they are the chief. And if we would bear this in mind more often when we give such drugs as opium, which constricts the small vessels of the body, and causes a flood-tide to press upon the heart and lungs as above-mentioned, the distressed breathing which is so frequent an accompaniment would not be produced. We have but to administer the opium, or other such drug, in combination with small doses of some diaphoretic or expectorant. Thus, let those persons who are subject to sleepless nights, and yet have not been able to take opium, because of the constant starting out of sleep, and the unbearable choking sensation which follows, try the accompanying prescription, and I do not think they will regret having made the experiment:—

R Tr. opii, (say) ℥x.;  
Sp. etheris nitrici, ℥xv.;  
Etheris chlorici, ℥xx.;  
Aque, ad. ℥iss.

Fiat haustus, nocte sumendus.

But this is departing from my subject. Let me, therefore conclude by saying that Solomon, upon whose words this treatment may almost be said to have been based, wrote nearly 1,000 years B.C.; and that, upon the whole, taking into consideration Dr. McKeogh's valuable contribution, as well as what is now brought forward, we cannot reasonably

doubt that to Harvey is due the honour, not of discovering the circulatory system, but only of being the first scientifically to describe it.

Trusting that these remarks may not be unacceptable,

I am, Sir,

Your obedient servant,

DANIEL BIDDLE, M.R.C.S.Eng., & L.S.A.  
Kingston-on-Thames, Nov. 29th, 1871.

### TWIN BIRTH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I send some particulars of a case of twin birth somewhat similar to those related in your impression of the 15th inst., taken from a few cursory notes made by me at the time.

On the 30th March, 1869, I was called on to attend Mrs. B., æt. twenty-five, who had been delivered of a healthy, well-developed, female child about four p.m. the day before, stated to have been a foot presentation; primipari. No afterbirth coming, and slight labour pains continuing, I saw her for the first time at ten p.m., and on making an examination I found the vagina cool and moist, but was unable to diagnose the presentation on account of the very contracted state of the os uteri. The pulse being 80, tongue clean, and skin cool, I determined to leave matters as much as possible to nature. Weak pains continued to recur during the night, the patient obtaining some sleep in the intervals and next day till twelve o'clock, when the os being more dilated, I ruptured the membranes, and the patient was delivered of another healthy female child at half-past three p.m., by breech presentation, this being as near as possible an interval of two days.

Now, in this case two other modes of treatment might have been pursued, but with what advantage I will not venture to predict. Firstly, I might have given ergot, and from the previous dilatation of the parts we might not expect evil consequences to ensue; or, secondly, I might adopt the directly opposite, and give opium, but as the patient obtained some sleep, and was not in the least exhausted, I did not consider it a necessity.

From the favourable termination of these two cases, and there being—in mine, at least—not the slightest tendency to collapse or hæmorrhage, which, I believe, is not unusual in such cases, I should feel inclined to follow a similar treatment again, unless such circumstances as the presence of convulsions, hæmorrhage, prolapse of funis, &c., indicated the necessity for immediate interference, although one eminent authority lays it down as "circumstances which would negative any delay in the delivery of the second child—1st, when artificial aid has been required with the first child; 2nd, when the second child presents preternaturally."

Now, as to the first, is it merely because artificial aid, such as delivery by the forceps, has been necessary with the first, that we should seek the immediate delivery of the second; or that the same assistance will be necessary with the second? Will not the dilatation produced by the first prepare the way for the second? May it not be a smaller child; or may not its osseous structures be less developed, so as to mould better to the passages? Will not the contractions of the uterus have more power from their concentration on the one child, and may not the pains become more powerful by giving time for the patient to recover from the shock of the first delivery?

As to the second. Should such a preternatural presentation as the upper extremities or thorax present, of course it would demand immediate interference. But if it is the lower extremities or breech—as in my case, although I was unable to diagnose it at first for the reason stated, it is probable I could have done so had I been there to examine immediately after the delivery of the first—if ergot failed, I would be justified in performing the locally dangerous and troublesome task of searching for the feet and bringing them down, and run the double danger of inducing fatal collapse by the suddenness of the second delivery, when all might terminate so favourably if left to Nature.

Should I have formed any erroneous opinions on this subject, perhaps some of our venerable professors of midwifery will be good enough to refute them. I daresay there are some among your numerous readers, like myself, placed in a country district, devoid of many opportunities of improving our knowledge except through the medium of your valuable paper, and who are often obliged to act on their own responsibility in difficult and urgent cases—time being all-im-

portant, they feel the greater necessity to be prepared for every emergency—and who shall feel equally grateful for the boon conferred.

I am, Sir,

Your obedient servant,

GREGORY SALE.

Medical Officer, Kilmeague and Robertstown Dispensary.  
Kilmeague, Nov. 18th, 1871.

### THE ILLNESS OF THE PRINCE OF WALES.

THE anxiety of the country was greatly increased by the death of the Earl of Chesterfield, who was seized with the same form of fever as the Prince, and at so nearly the same time. Moreover, the illness of others who had lately accompanied the Prince increased the forebodings, for which there have been good reasons. Medical readers; however, do not require to be told that these circumstances are of little value as guides. Typhoid, although it runs a definite course enough, not unfrequently gives rise to a variety of secondary accidents, any one of which may prove fatal, as in the case of Lord Chesterfield. So long as the physicians in attendance certify that the course of the fever is regular, and that their royal patient's strength is not failing, we have a right to hope for a happy issue. This fact has been so pressed upon the public, however, that it is possible too many may lose sight of the dangers of relapse, or of any of the complications or sequelæ to which we last week alluded. Although up to the time of our going to press we are happy to observe that the bulletins denote favourable progress, we cannot shut our eyes to the dangers ahead, nor would we encourage the public to forget that these are both numerous and formidable.

It seems needless to enter at length upon the origin of the Prince's attack. Those who have seen most of fever are the least confident of their ability in any given case to put their finger on its cause, and in spite of all that has appeared we have grave doubts as to its origin in the Prince's case.

## Medical News.

**The Royal Society.**—The anniversary meeting of the Fellows of this Society, for the election of Council and officers for the ensuing year, and for the presentation of the medals, was held on Thursday, at Burlington House. General Sir Edward Sabine, R.A., occupied the chair for the last time in his capacity of president, and delivered the annual address. The medals were presented to the gentlemen named in our last, as the probable recipients. The Copley medal to Mr. Julius Robert Mayer, of Heilbronn; one of the Royal Medals to Mr. George Bask, in recognition of his scientific researches in zoology, and the other to Dr. John Stenhouse, LL.D. for his valuable contributions to chemical science. The following gentlemen were then elected council and officers for 1871-72. President, George Biddell Airy, M.A., D.C.L., in the room of General Sir Edward Sabine, resigned; treasurer, William Spottiswoode, M.A.; secretaries, William Sharpey, M.D., LL.D., and Professor George Gabriel Stokes, M.A., D.C.L.; foreign secretary, Professor William Hallowes Miller, M.A., LL.D. Other members of the Council:—George James Allman, M.D., George Burrows, M.D. (President of the Royal College of Physicians, London), Prof. R. B. Clifton, M.A.; H. Debus, Ph.D., George Bask, (President R.C.S. England), Professor Duncan, M.B., Professor George C. Foster, B.A., Mr. Francis Galton, M.A., Thomas A. Hirst, Ph.D., Sir John Lubbock, Bart., M.P. Sir James Paget, Bart., D.C.L., the Earl of Rosse, D.C.L., Sir Edward Sabine, K.C.B., Isaac Podhunter, M.A., and Sir Charles Wheatstone, D.C.L. and John Ball, M.A.

**University of London.**—The following are the gentlemen who passed the recent honours examinations, second M.B. examination:—*Medicine: First Class*—William Henry Allchin, Scholarship and Gold Medal, University College; Henry Edward Southee, Gold Medal, Guy's Hospital; *Second Class*—Robert Wishart Lyell, King's College; Ernest Alfred Elkington, General Hospital, Birmingham; *Third Class*—William Ward Carr, Alfred Henry Carter, University College; Richard Clement Lucas, equal, Guy's Hospital; *Obstetric Medicine: First Class*—Richard Clement Lucas, Gold Medal, Henry Edward Southee, Guy's Hospital; *Second Class*—John Henry Humphreys, Gen. Hos., Birm.; Robert Wishart Lyell, King's College; *Third Class*—Alfred Henry Carter, William Henry Allchin, University College; Ernest Alfred Elkington, Gen. Hos. Birmingham; *Forensic Medicine: First Class*—Ernest Alfred Elkington, Gold Medal, Gen. Hos. Birm.; *Third Class*—Robert Wishart Lyell, King's College; Henry Edward Southee, Guy's Hospital.

**Election of Examiners in the Queen's University in Ireland.**—On November 22nd, the following gentlemen were elected by the Senate as examiners for the year 1872-73:—*Medicine*—Professor Colahan, M.D., Professor of Practice of Medicine in Queen's College, Galway; *Surgery*—John K. Barton, M.D., Surgeon to the Adelaide Hospital, Dublin; *Midwifery*—T. More Madden, M.D., late Assistant-Physician Rotundo Hospital; *Materia Medica*—Thomas Wrigley Grimshaw, M.D., Physician to Stevens, and Cork street Fever Hospital; *Medical Jurisprudence*—Edmund W. Davy, M.D., Professor of Medical Jurisprudence in the Royal College of Surgeons. It is said that the senate was guided in its selection of these gentlemen from a large number of candidates, by the fact of their being without, exception, lecturers on the subjects of the examinership.

**Edinburgh Obstetrical Society.**—The following office bearers were elected on November 22nd:—Presidents, Dr. L. Ramsay Thompson, of Dalkeith; Vice-Presidents, Professor Simpson, Dr. J. Matthews Duncan; Treasurer, Dr. James Young; Secretaries, Dr. R. Peel Ritchie, Dr. J. Andrew; Council, Dr. A. Keiller, G. Stevenson Smith, Esq., Dr. T. H. Patteson.

**A Public Medical Election.**—A numerous attended meeting of the vestry of Lambeth was held on Thursday last for the purpose of electing a medical officer for the parish. The chair was occupied by Mr. Robert Taylor. At a committee meeting on Wednesday, the number of applicants for the situation had been reduced from seventeen to twelve. The candidates having each appeared before the vestry in order to answer any question that might be put to them, the reporters were called in, it having been decided that the public should be excluded until the taking of the division on the last two competitions. The result of the division, which was taken amid much excitement, was the election of Dr. McCormack by 58 votes, against 46 given to Dr. Cortis. The chairman having congratulated Dr. McCormack on his appointment, and Dr. McCormack having acknowledged thankfully the honour conferred upon him, the proceedings ended in the usual way.

**Increase in the Consumption of Opium.**—The *Manchester Guardian* says—Beer is not the only luxury of which it is found that the demand is to a large extent regulated by the supply, nor England the only country which is learning this lesson to its cost. The report of Consul Cain, of Hankow, published in the *Bombay Gazette*, points to a greatly increased and increasing consumption of opium in China as the direct result of its more extensive cultivation. Hitherto the Chinese have been content chiefly to import their opium, and its cultivation at home is even now strictly forbidden by law. So little, however, is the legal prohibition regarded that in one of the western provinces of the empire half the land is now taken up with crops of the poppy, and its cultivation is rapidly spreading. The mandarins appear to be utterly corrupt. They derive a considerable revenue from the native opium, and merely use the penalties which the law has enacted against the growers as a means of extortion. But though the home manufacture of opium has greatly increased, the importations, strange to say, have not fallen off, but have increased also. The cheap native drug, in fact, merely serves to introduce the more expensive imported article. The taste which the one creates the other alone can satisfy. This state of things may be highly agreeable to the Indian Government and to Indian taxpayers, but for China it is about as disastrous as can well be imagined.

**Crowded Towns.**—Comprehensive, yet cautious, measures are necessary for the improved house accommodation of the working classes of our great towns over large areas of habitation; that, as for the overcrowding of persons in a house, so also for the overcrowding of houses on a given area, there should be a limit to density of population fixed by law, at all events, in the building of dwelling houses on fresh ground, as well as in rebuilding them on ground previously occupied; and that, for the success of such measures, the establishment of superior administrative authorities, with adequate powers, is as essential as it is for the execution of measures intended to prevent the adulteration and to secure the good quality of food; or, again, for those which protect labour from abuses and unhealthy conditions known to sap the vigour of the race.—*Fool Journal*.

**The Murphy Annuity Fund.**—We have been requested to publish the following statement:—The funds subscribed and promised by the profession towards the purchase of this annuity have already amounted to a sum sufficient to secure for Dr. Murphy a life annuity of fifty pounds. Some inevitable delay in obtaining the necessary age certificates, &c., has prevented the treasurer (Dr. Arthur Farre) from purchasing the annuity. The papers, however, will be ready, and the amount purchased, on January 5th, 1872. In the meantime, the amount subscribed being in excess of that which is necessary to purchase an annuity on the sole life of Dr. Murphy, and many of the friends of Dr. Murphy being desirous to include in the provision his wife, who would otherwise be left destitute at his death, it is intended that an effort shall be made to increase the existing surplus to a sum sufficient to extend the proposal over the two lives. For this purpose £130 will be wanted, and it must be collected before the close of the year. Mr. Campbell de Morgan, 51 Upper Seymour street, will act as treasurer of the supplementary fund, and Dr. Wiltshire, 57 Wimpole street, W., as honorary secretary. When the full amount is collected it will be handed over to Dr. Farre, the treasurer of the original fund, who will invest the whole sum in the names of the trustees originally announced.

#### Wrist-Joint Dislocation.

ACCORDING to Francis L. Parker, M.D., Prof. of Anatomy in the Medical College there are 33 cases of so-called dislocations of the wrist-joint on record (omitting the cases of W. Parker and René), including his own, viz., case of dislocation of the wrist-joint backwards. Of these 23 are said to have been luxated backwards and 10 forwards, and of this entire number only 7, 5 backwards and 2 forwards, are free from all objection. Of the 26 cases of doubtful or unsatisfactory dislocations, 16 were complicated with fracture of one of the bones or processes connected with the joint; 3 were compound, 3 were incomplete, 2 were arthritic or pathological specimens, and 2 were objected to from other causes. Of the 33 so-called dislocations, the sex is recorded here in 14 instances; of these 11 were males and 3 were females. Of the 7 cases classed as genuine ones 1 post-mortem was made (case of M. Malle), which confirmed the diagnosis; in 6 remaining cases the patients regained the use of the limb in a very short time, without a tendency to displacement or deformity. Of these 7 cases accepted as genuine, 2 backward dislocations were produced, the force of the fall being received, in one instance, on the dorsum of the hand (Hamilton's); in the other upon the palmar surface (Parker's); in M. Malle's case, a forward displacement, the presumption is that the patient fell on the palm of his hand, but this is not definitely stated; and in the 4 remaining cases this point is not specified. He lays down the following practical conclusions which may be derived therefrom: 1st. The wrist-joint may be dislocated backwards or forwards without fracture or a rupture of the integuments; both are extremely rare; the backwards displacement is the most frequent. 2nd. Cases of so-called dislocation of the wrist may be associated with fracture of the radius and ulna, or with either of these bones separately, with both styloid processes, or either of them, or with fracture of the articulating surface of the radius; no instance has been recorded of a dislocation of this joint complicated with fracture of the carpal bones. 3rd. Dislocation of the wrist backwards or forwards may be complicated with rupture of the integuments anteriorly or posteriorly or laterally, with or without fracture of the styloid processes.—*Transactions of the South Carolina Medical Association*.

## NOTICES TO CORRESPONDENTS.

**A SUBSCRIBER.**—It is necessary to use a proper inhaler for the administration of oxygen. There are two forms in use in America. In this country, Mr. George Barth, of Duke street, Oxford street, is the only maker of the apparatus. His inhaler is most convenient, and he also supplies the gas.

**MR. FRISNEATHER.**—The paper shall appear shortly.

**DR. JOHNSON.**—It will be interesting.

**E. R.**—Your letter received, also the Journal. The package has been forwarded to the address indicated, and, we hope, will arrive safely. Your enclosure has been duly forwarded. We shall be pleased to hear from you again.

**DR. HIND.**—We have received nothing.

**R. E.**—We shall feel obliged if you will kindly write legibly. Some words in the last M.S. we could not decipher.

**ERRATUM.**—Metropolitan Free Hospital. Dr. C. Drysdale writes to say that the second case reported in our last week's issue (Nov. 22), was not under his care, but under that of Mr. Sheffield, as reported by Mr. Kipling, of the Metropolitan Free Hospital.

**DR. POWELL, Newington.**—Is thanked for his very kind note.

**LEIBNER.**—In the *Allgemeine Wiener Medizinische Zeitung*, for November 25th.

**DR. BRUCE JONES, Mr. Bulmer, Mr. Carter, Dr. Rilge, Dr. Fox, Mr. Bidule:** thanks.

**STUDENT.**—There are considerable additions and alterations in the fifth edition. If, as you say you can buy the fourth edition at half-price, we would still advise you to wait until you can afford the last. See Sir Thomas Watson's preface.

**CHORAL.**—Such symptoms are not uncommon.

**MR. H. F. L.**—Bimeconate of morphia, as prepared by Mr. Squire, is the most reliable form we have seen.

**MR. MICHAEL DUKE, Liverpool.**—Your case comes scarcely within our province as medical journalists, but as you appear to have been badly treated, forward us full particulars, and we will give you any assistance in our power.

The following communications are unavoidably held over:—

“Heated applications to Catheter and Bougies.” By R. Hanslip Esq.

“On the Treatment of Eczema.” By J. L. Mitton.

“On Syphilitic Laryngeal Disease,” by Mr. Morgan, F.R.C.S.L. &c.

## VACANCIES.

Hospital for Sick Children, London. House-Surgeon. Salary £ 0.  
Earlswood Asylum. Assistant Medical Officer. Salary £ 50.  
Seaman's Hospital, Greenwich. House Physician.  
Bradford Fever Hospital. Resident Medical Superintendent. Salary £120, with board.  
Blything Union. Medical Officer. Salary £43, with extras.  
Jersey Dispensary. Medical Officer. Salary £100.  
North Stafford Infirmary. House Physician. Salary £80.  
Amersham Union. Medical Officer. Salary £70.  
University College Hospital, London. Assistant Obstetric Physician.  
Great Northern Hospital, London. Honorary Surgeon.

## MEETINGS OF THE LONDON SOCIETIES.

**WEDNESDAY, Dec. 6th.**—HUNTERIAN, 7½ P.M. Council.—8 P.M. Ordinary Meeting.  
**OBSTETRICAL.**—8 P.M. Mr. Eugene Goddard, “On a Successful Case of Ovariectomy during Pregnancy.”—Dr. Brunton, “On Fibroid Enlargement of the Uterus.”—Dr. Edis, “On the Systematic Examination of the Uterus, with the view of rectifying Malposition of the Fœtus.”—Dr. Meadows, “On a Case of Extra-Uterine Fœtation.”  
**MEDICO-PSYCHOLOGICAL ASSOCIATION** (32A George street, Hanover square), 8 P.M. Clinical Reports, Morbid Specimens, &c.—Dr. Maudsley: “Is Insanity on the Increase?”  
**ROYAL MICROSCOPICAL SOCIETY.**—8 P.M. Mr. J. Bell, “On Fermentation and its Results.”—Dr. L. Beale, “On the Nerves of the Capillary Vessels, and their probable Action in Health and Disease.”  
**SOCIETY OF ARTS.** 8 P.M. Mr. Bailey Denton, “On Sewage.”  
**Thursday, Dec. 7th.**—HARVEIAN SOCIETY OF LONDON, 7½ P.M. Special Council Meeting, 8 P.M. Mr. Gascoven, “On Spermatorrhœa and its Treatment.”  
**Friday, Dec. 8th.**—CLINICAL.—5½ P.M. Dr. Ogle, “On the Temperature in certain Affections of the Nervous System, and especially in Tetanus.”—Dr. Habershon, “On Heart Disease.”—Dr. Broadbent: “Tumour in left half of Floor of Fourth Ventricle, with small Tumour in Cerebellum.”  
**Monday, Dec. 11th.**—MEDICAL SOCIETY, 8 P.M. Ordinary Meeting.

## OPERATION DAYS AT THE LONDON HOSPITALS.

**WEDNESDAY, Dec. 6.**  
MIDDLESEX HOSPITAL.—OP. FEBRUUS, 1 P.M.

## APPOINTMENTS.

**DAVIES, J., M.D., M.R.C.S.E.,** Surgeon to the Abersychan Iron Works, has been appointed Surgeon to the Ebbw-vale Steel Works.  
**EAGAR, Dr.,** Assistant House-Surgeon to the Sheffield Hospital.  
**FERGUSON, A., F.R.C.S.E., L.R.C.P. Ed.,** Medical Officer for the Parishes of Peebles, Stobo, and Manor.  
**GRIFFITHS, W. H., Ph.D., L.R.C.P. Ed., L.R.C.S. Ed.,** has been elected Assistant Librarian to the Royal College of Surgeons in Ireland.  
**JOHNSTON, R.,** Assistant House-Surgeon to the Nottingham Hospital.  
**M'SWINEY, G. H., M.D., M.C.,** House-Surgeon to the Liverpool Infirmary for Children.

## Marriages.

**CAMPBELL—RIGBY.**—On the 28th ult. at St. Paul's, Westbourne grove, London, Peter Campbell, M.D., Bridge of Allan, N.B., to Phœbe, daughter of the late Peter Rainfor's Rigby, Liverpool.  
**MILLS—MERRYWEATHER.**—On the 23rd ult. at St. Stephen's Church, Clapham, Samuel Mills, M.R.C.S., of Southampton street, London, to Mary Compton, eldest daughter of M. Merryweather, Esq., of Clapham.  
**ROBINSON—MALDEN.**—On the 28th ult. at East Kirby, Lincolnshire, Dr. Robinson, of 19 Guildford street, Russell square, London, to Mary Roberta, only daughter of the late Mr. Robert Malden, of the Manor House, East Kirby.

## Deaths.

**DAVIS.**—On the 26th ult., Creswell Davis, M.R.C.S.E., of Onslow gardens, South Kensington.  
**DILL.**—At Western Cottages, Brighton, John Dill, M.R.C.S.E., aged 94.  
**NAPPER.**—On the 24th ult., Thos. Napper, M.R.C.S.E., of Ockley, Surrey, aged 61.

## COOKESTOWN HOUSE, INSTITUTED FOR

## THE MEDICAL TREATMENT OF THE INSANE OF BOTH SEXES.

This highly respectable Manion in no respect resembles, either internally or externally, what is usually known as an Asylum. The Demesne, Conservatories, Graperies, and Grounds are unusually extensive, and in good condition.

There are Billiard Tables for both sexes, with indoor and outdoor amusements, including Vehicles.

Cookestown House is within three miles of Carrick-on-Suir Station, with a like distance from Fiddown, both on the Waterford and Limerick Lines, and in connection with the G. S. & W. and Kilkenny Lines.

For terms, and Form of Admission, apply to the Resident Physician, JOHN PEPPARD, M.D. &c.

Cookestown House, Piltown, co. Kilkenny.

## THE MIDLAND RETREAT.

(Near Maryborough, on the Great Southern and Western Railway.)

**FOR THE RECEPTION AND TREATMENT OF THE INSANE,** and of persons suffering from a disturbed state of the Nervous System, under the direction of DR JACOB, Physician to the Maryborough District Lunatic Asylum (260 patients), Surgeon to the Queen's Co. Infirmary, &c.

THE ESTABLISHMENT consists of separate and commodious residences for the reception of Ladies and Gentlemen. Each situated on extensive grounds, with large, well-enclosed gardens. They are handsome, well-furnished country residences, where the patients enjoy the comforts and inducements of a private house. Restraint is not, under any circumstances, practised, and the closest attention is paid to the medical treatment and general health of the patients.

**APOTHECARIES' HALL, LONDON.**—The next EXAMINATION in ARTS will be held at the HALL on FRIDAY and SATURDAY, JAN. 26 and 27, 1872. A Syllabus of the Subjects for Examination may be had on application.

An Examination in ARTS will again be held on 26th and 27th APRIL, 1872.

R. H. ROBERTSON, Secretary to the Board.

**SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.**—Founded 1788. Incorporated by Royal Charter, 1864. The Members are reminded that a Quarterly Court of Directors will be held on the 10th of January next, at which candidates for a Mission into the Society can be proposed. It is desirable that the forms of proposal be filled up and forwarded to the Secretary at least a week before the meeting. The forms of proposal may be obtained of the Secretary. The benefits of the Society are restricted to the families of deceased members of not less than two years standing. The Secretary attends at the office every Wednesday and Friday, from 4 to 5 o'clock.

J. B. BLACKETT, Secretary.

53 Berners street, W., Dec. 3rd, 1871.

## CLINICAL LECTURES

ON

## DISEASES OF THE EYE,

DELIVERED AT THE ADELAIDE HOSPITAL.

By H. R. SWANZY, M.B., L.R.C.S.I.,

Ophthalmic Surgeon to the Hospital, and Surgeon to the National Eye and Ear Infirmary; late Assistant to the late Professor Von Graefe, Berlin.

### LECTURE III.

*Common, or Concomitant Strabismus.*

GENTLEMEN,—The form of squint which you see exemplified in these two children (a boy, *æt.* 8, and a girl, *æt.* 10,) is the most frequent one. We call it strabismus convergens concomitans. In the boy the amount of the deviation of the squinting eye towards the nose is three lines, measured from the centre of the under lid—which we may regard as the normal position of the cornea when the gaze is directed straight forward—to the position which it now occupies. If you observe him, you will find that this child does not always squint with the same eye, but that he changes or 'alternates,' squinting sometimes with the right and sometimes with the left eye. He sees equally well with each eye, and, according to his mother's account, which I am very ready to believe, the deformity made its appearance for the first time about two months ago. In the little girl the deviation is somewhat greater, and the left eye squints constantly, the right eye alone being used to fix objects. As well as I can make out, for the child is shy, the vision of the squinting eye is not so good as that of the straight one. She has been squinting for the last year. In the boy, then, we have an alternating, and in the girl a monolateral strabismus. In each case the strabismus is 'concomitant,' that is to say, with whichever eye the

boy squints, the degree of the squint is the same—it is not greater when he squints with the right eye than when he squints with the left, or *vice versa*. And in the girl too, if you cover the healthy eye with one of your hands, and holding up a finger of your other hand in the middle line a little distance in front of her, cause her to look at it with the left or squinting eye, in order to bring the yellow spot to bear on the object, she will be obliged to roll the eye outwards to the extent of three and a half lines (the degree of the squint). If now you manage to get a look at the right eye, under your hand, you will find that it has become deviated inwards for three and a half lines, and this is called the secondary deviation, and, as here, is always *equal* to the primary one in concomitant strabismus. In paralytic strabismus, on the other hand, the secondary deviation, for reasons which I shall explain to you some other time, is *greater* than the primary, and therefore this is a point which you must always investigate. It is very common for strabismus to make its appearance in children from the fourth to the ninth or tenth year of age, when they commence to use their eyes more continuously for near objects, in learning to read, write, &c. The parents then puzzle themselves with all kinds of theories to account for the squint, seeking its cause in worms, in a habit the child is supposed to have of looking at a lock of its own hair which falls somewhat low over the forehead, in the imitation of other squinting children, and so on. You will also find, if you should practise in this country, that the public are on the whole rather indifferent to the presence of squint in themselves or their children, regarding it at worst as a deformity which is of no consequence for the integrity of the organs themselves; or, you will find that strabismus is regarded as a "nolli me tangeri"—a mysterious disease, any interference with which is calculated to produce a worse deformity. Indeed, one requires merely to walk through our streets to see how deeply rooted these popular errors are.

Let us now inquire into the cause of concomitant convergent strabismus. Donders found that, almost without exception, that condition of refraction of the eye termed hypermetropia existed, when strabismus was developed, and it then soon became apparent that hypermetropia was in fact the cause of squint.

In hypermetropia, the antero posterior axis (AB) of the eyeball is too short, so that instead of the retina being

situated at C B D, as in the normal eye (emmetropia), it is situated at  $c' b' d'$ . We know that rays of light (R R) from objects at fifteen feet distance and more, falling into the eye, do so with so very slight a divergence, that for all purposes they may be regarded as parallel, and we know that in the normal eye these parallel rays are brought to a focus on the retina at B by the power of refraction of the cornea (I A E) and lens (L) alone, without any exertion on the part of the muscle of accommodation, and that thus exact images of distant objects are formed on the retina. In hypermetropia, however, the power of refraction of the eye is insufficient to bring parallel rays to a focus on the retina ( $c' b' d'$ ); and, in order to accomplish this, it is necessary that the crystalline lens should be made more convex—as indicated by the dotted line D. This occurs through means of the ciliary muscle (M)—muscle of accommodation—which is thrown into action. In the normal eye it is only required of this muscle to come into play when near objects are looked at, because the rays from these fall into the eye so divergent that they could not meet in a focus on the retina, unless the lens were accommodated for them. If, however, the hypermetropia eye finds it necessary to use its power of accommodation for distant objects, which the normal eye sees without any exertion, the strain upon its ciliary muscle for near objects must greatly exceed that demanded by the normal eye for the same purpose.

Now, it has been found by physiological experiment, that, even in the normal eye, the greater the angle of convergence of the axis of vision is (i.e., the angle formed by two right lines drawn from each yellow spot to the object looked at), so much the more actively can the ciliary muscle exert itself; they are in fact associated actions. The hypermetrope unconsciously avails himself of this physiological fact, and, in order to aid his muscle of accommodation, he increases the angle of convergence of his visual axis, by looking at the object with one eye, while he directs the axis of vision of the other more towards his nose. You might very fairly ask: How is it then that these children do not see double, for the image of the object which is formed in the straight eye on the macula lutea, must be formed on an eccentric part of the retina in the squinting eye, and we know that for single vision it is necessary that the image should fall on identical spots in the retina? The answer is: These individuals do not see double, because, as we believe, the image in the squinting eye is suppressed by a mental act. In other words, to prevent the confusion which double images would produce, the centre of perception in the brain, which receives impressions from the eye, disregards the image belonging to the squinting eye. This voluntary exclusion of a double image is quite analogous to the power we possess, and often exercise, of listening to a conversation in which we are interested, while another carried on close at hand passes unperceived. If we attempt to listen to both conversations at the same time, the result is that we hear neither perfectly.

In this boy, as I have already remarked, the squint alternates, sometimes it is in one eye, sometimes in the other. You may see that this is the case if you observe him for a few minutes while he looks round the room. But a more certain and quicker way to decide the question is by making

him look at a finger, which you hold up, while you cover one of his eyes (e. g., the left) with your other hand. Then, upon removing the latter, he will continue to fix with the same eye (the right) as before. If you now cover the fixing eye (the right), the squinting eye (the left) turns out to look at your finger, while, under your hand, its fellow (the right) becomes the squinter, and when you again remove the covering hand you will find that the patient continues the fixation with the left eye. This is the form with which squint generally begins, and it is very desirable that it should come under treatment at this period; because, so long as it continues to alternate, each retina in its turn is put into use, and the vision of each eye remains good. If, therefore, for some reason it should be desirable to postpone the operation for some months, you should direct the parents to bind each eye in turn for a quarter or half an hour daily, while the child is at play, in order to keep the strabismus alternating. At last (it may be in weeks or in months) the squint, if left to itself, becomes 'monolateral,' one eye or the other becoming permanently the squinting eye. Very soon then the vision of the squinting eye becomes affected, because it is constantly excluded from the act of vision, and, like any other organ of the body, in order to its health, the retina requires to be in use. At first this amblyopia ex anopsia, as it is termed, is slight, and attacks each part of the retina in a proportional degree. Gradually the yellow spot is attacked more actively than the rest, so that its acuteness of vision sinks to a level with that of the surrounding retina. If, in the latter stage, the squinting eye be made to fix an object—by covering the opposite eye, as I have just shown you—you may perceive little oscillating movements in it, as though it were seeking for the spot in the retina it could see best with. In the course of time, the yellow spot and the outer half of the retina become so deteriorated in their functions, that the inner half gains the supremacy, and then when such an eye is made to fix, instead of turning outwards—as it otherwise would do—it turns still more towards the nose, in order to bring the inner part of the retina to bear on the object. The determination of these three stages of the amblyopia consequent on squint is of importance in the prognosis, for the first may be perfectly cured by restoring the eye to a straight position, the second can usually be much improved, but the last is incurable. Moreover, although even if the squinting eye be quite blind, the tenotomy is capable of producing an admirable cosmetic effect, still this will be all the more perfect the better the vision of the squinting eye is. As a general rule then, for the reasons I have just stated to you, the cure of strabismus should not be postponed.

It has been proposed, and very rationally too, to cure strabismus concomitans, in its early stages at least, by the use of convex glasses, to correct the existing hypermetropia. There are however in practice few cases to which this treatment is applicable; for, in the first place, you dare not give spectacles to be constantly worn, as they should then be, by these small people, who get such frequent falls on their faces, and are exposed to knocks from their playfellows, &c. Then, in the second place, it is remarkable that convex spectacles do not always correct the strabismus, even when worn soon after its appearance, the patient continuing to squint with the spectacles on. This is a fact which I cannot explain, unless, as Von Graefe used to think, it depend on a psychical habit, by which the act of squinting has been united with the desire to see an object sharply. Indeed, you will sometimes find patients who persist in squinting, even when they wear glasses which are so much stronger than is necessary to correct their hypermetropia that the strabismus is actually disturbing to vision. No doubt if proper convex spectacles could be worn before there was any squint, then the latter would not be developed.

The old method (Dieffenbach's) of performing tenotomy for squint was founded on a principle of cure similar to that which holds good for division of the Achilles tendon in cases of talipes equinus. It was thought, namely, that when the tendon of the rectus internus was divided

at a little distance from its insertion into the sclerotic, the eye then fell into its normal position, and that a new piece of tendon was formed to fill up the gap at the place of division. This process however very frequently did not take place, and the result was then, at best, "a stiff eye," the rectus internus being powerless to roll the eye inwards. But matters often became worse, for, the balance of power being lost between the rectus internus and the rectus externus, the latter muscle had no opposition in its tendency to roll the eye outwards, and thus a permanent outward strabismus was often developed. Still more certain was a result of this kind, when, as frequently happened, the belly of the muscle itself was divided posterior to its passage through the capsule of Tenon, and the capsule extensively lacerated. No wonder that the operation fell into disrepute with the profession and the public.

Von Graefe introduced the squint operation as it is now practised. His method has been 'modified' by different surgeons, but I have not yet had any reason to depart in any way from the proceeding as he taught it. It is as follows:—Let us suppose that the left internal rectus is to be operated on. Chloroform having been administered, the lids are held open with a spring speculum, and an assistant everts the eyeball with a forceps, and holds it thus during the whole operation. With a forceps a narrow fold, containing conjunctiva and subconjunctival tissue, is then seized, just over the insertion of the tendon of the rectus internus into the sclerotic, and is snipped with a pair of fine scissors made for the purpose. These are then passed on into the opening, and a passage burrowed obliquely to the upper edge of the tendon; then, withdrawing the scissors, the surgeon passes one of these blunt pointed strabismus hooks along the passage until it gets just beyond the upper edge of the tendon, and then pressing the point somewhat firmly against the sclerotic, he turns the hook, and slips it between the tendon and the sclerotic. Having thus secured the tendon on the hook, he separates it from its attachment to the sclerotic, very close to the latter, with the scissors. Then, with a smaller hook, he searches below and above for any remains of the expansion of the tendon which may not have been divided from their attachments, for if any of these be left they might diminish the effect of the operation seriously. The result of this proceeding is that the muscle recedes, and becomes attached at a point of the globe further back, and so loses, what we may consider to have been, its excessive power to rotate the eye inwards, *i.e.*, to produce a squint.

Squints, however, are of different sizes, and we must therefore dose our operation according to the case. Such an operation as I have just described would correct a strabismus of about two lines, or two and a half lines; but if the displacement amounts to four lines, you will require to perform a supplementary operation on the internal rectus of the other eye, and if it amounts only to one and a half lines, you must draw the edges of the conjunctival wound together by means of a suture, so that the effect of the operation may be diminished to the desired extent. By these means you will be enabled to correct this deformity with great precision. Some of you have already seen strabismus operations here, and I hope in a few days to operate before you on this boy, at the National Eye Infirmary.

After the operation, the eye is kept bandaged for some days. The edges of the conjunctival wound are never drawn together with sutures for the purpose of furthering a good healing process, for the latter proceeds with an *invariably* favourable result. Nor, indeed, could sutures be of any avail for this purpose, inasmuch as, the conjunctiva being such a delicate tissue, an exact approximation of the edges of a wound in it would be a difficult feat to accomplish. When sutures are applied to the conjunctival wound after a squint operation, it is always in order to diminish the effect of the tenotomy, as I have just explained to you.

The after treatment of a squint operation is of the greatest importance. You will usually have to prescribe the convex spectacles which correct the hypermetropia, and direct

them to be worn when the patient is engaged at near work (reading, writing, sewing, &c.) and, if his age admits of it, they should also be worn for distant objects, particularly when, as is often desirable, you have still left a slight convergence over. The tendency is for the effect of the tenotomy to increase within the first few months, so that if a slight convergence be left immediately after the operation, it will gradually disappear, and if the eye be made quite straight, by limiting or doing away altogether with the use of the convex spectacles, you will be able to retain this position permanently. In some cases the use of convex spectacles must be continued for a year. Indeed, the after treatment is of as great importance as the proper doing of the operation itself, and neglect of it is one of the most frequent sources of disappointment in these cases.

### THE QUESTION OF OPERATIVE INTERFERENCE

IN

### SYPHILITIC LARYNGEAL DISEASE.

BY J. MORGAN, M.D., F.R.C.S.I.,

Surgeon to Mercer's and to the Westmoreland Lock Hospitals, Professor of Surgical and Descriptive Anatomy R.C.S.I.

THE distressing effects of the formation of the later syphilitic deposits in the larynx are generally the cause of the greatest anxiety to the surgeon, and the question of how far operative aid can be relied on, to give permanent benefit, is one of such difficulty, that the following practical illustration will be of advantage.

In the earlier stages of syphilitic infection, laryngeal inflammation may run so high and evidence itself with such acuteness, that the happiest results have followed from the opening of the air passage; and as later observations have shown that this acute inflammation does not extend itself below the region of the vocal cords, the operation is reduced to the simpler proceeding of laryngotomy proper, and is accompanied by so little danger that for the acuter and earlier inflammations of the larynx there may be but little question of the utility of the operation in cases of urgency.

It is however unfortunately during the later stages of the march of the constitutional infection, that laryngeal disease evolves itself, and being associated with signs of declining health, appeals to the careful consideration of the surgeon. When the first outburst of the syphilitic infection has passed away, and where the subtle and uncertain developments of the gummy or tertiary deposits manifest themselves, it is then that the subject becomes important and debatable.

The larynx may be secondarily affected from the extension of gummatous ulcerations which may occur so low down in the throat as to affect the organ itself in the subsequent ulceration which ensues; such gummatous ulcers may affect the pharynx, the base of the tongue, the half arches of the palate or tonsils, and lead to much pain and copious purulent expectoration with loss of voice, threatening rapid suffocation. The extent of the lesion may hardly be appreciated during life, but may be of extraordinary extent, and should render any forecast of the result of late laryngeal disease in syphilitic patients, to be given with great caution and reserve. I have seen cases where the gummatous and sloughy ulceration had extended to the larynx, involving the left cornu of the os hyoides, the upper part of the thyroid cartilage, both of which were necrosed, as also the left arytenoid cartilage, the mucous membrane of the larynx was ulcerated and swollen, yet not to a degree sufficient to ~~cause death~~ by suffocation. The larynx may be alone affected by the disease, indicating the usual evidences of such affection, by hoarseness, attacks of difficult breathing, with pro-

fuse semi-purulent expectoration, so essentially different from the nummular sputa of advanced phthisis. On *post-mortem* examination the epiglottis, false vocal cords, and all the upper part of the laryngeal membrane are frequently found deeply ulcerated.

The ubiquity of these gummatous deposits so characteristic and difficult of definition or limitation, renders the diagnosis or prognosis of much difficulty. Thus were certain that the disease was confined to the upper part of the laryngeal apparatus, operative interference might be of use in allaying the cough, and the irritation consequent on disease about the vocal cords; but, as there is much difficulty in arriving at such conclusion, and as the fact of the occurrence of diseased action on the upper part, oftentimes indicates its existence also in the lower part, operative aid offers but slender hopes, and should, I think, be undertaken only after careful consideration, and in circumstances of great gravity. I have had the opportunity of examining several specimens of diseased laryngeal apparatus, and I have invariably found the diseased condition so very extensive, that very faint hopes only could be entertained of any permanent relief. On the other hand, where laryngitis of an acute character has lighted up, associated with ulcerations, in the earlier stages of the syphilitic taint, I have seen the best results from operation; and a patient all but asphyxiated, may almost be brought to life. Where acute laryngitis ensues, the laryngoscope gives great information, the vocal cords may be seen much swollen, and the upper part of the laryngeal and epiglottic membrane intensely congested and oedematous.

It is evident, however, from the nature of the change that takes place, and the effects of the disintegration of the gummatous deposit, that no favourable augury can be given; that even should the ulcerations heal, they will leave a cicatrisation and narrowing, which will probably cause permanent inconvenience, or become so urgent as to necessitate the opening of the wind-pipe. The loss or change of voice is all but irrecoverable, and the liability to spasmodic suffocation is the cause of constant solicitude.

The larynx may not only suffer from such ulcerations, but the trachea itself, down to, and into the bronchial tubes, may be affected, and in this consists one of the great difficulties in the use of operative interference. The ulceration on the one hand, may have extended deeply and extensively into the respiratory channels; and on the other, the same condition of cachexia which induces the deposit in the laryngeal or tracheal region, develops them, in great probability, in the other internal organs.

While, therefore, in the earlier stages of syphilitic infection, operative interference—save for oedema of the glottis, or an acute inflammation, will seldom be necessitated, its utility in laryngeal disease, the result of gummatous ulceration, is to be questioned as of any permanent benefit, if even we were satisfied with the great aid derived from the laryngoscope, that the disease was confined to the upper part only of the wind-pipe, we might hope something from operation, in allowing the parts rest, in the more free application of topical remedies, and in the relief given to the patient.

The following practical illustration shows the difficulties that are met with in arriving at such a conclusion as would justify our opening the trachea, previous to the occurrence of urgent laryngeal symptoms; as the period in which the greatest benefit might be anticipated:—

A gentleman, æt. forty-three, always of energetic, robust, and active habits, contracted disease eighteen years previously. He had been a resident abroad, and had suffered from suppurating bubos, rash, alopecia, and the earlier evidences of a syphilitic taint. He had been now married six years, his wife having had miscarriages, but never a living child. He suffered for the last two years from various late phenomena of syphilis, nodes, nocturnal pains, and paralytic affection: from these he recovered under treatment. His laryngeal symptoms first appeared when in the south of England, ten months previously; he suffered from slight hoarseness, spasmodic cough, hurried breathing and profuse expectoration,

which became after a time mixed with purulent matter; the chest sounds were clear, and the heart's action without vigour. The symptoms gradually increased in urgency, in spite of treatment; the larynx became painful on pressure; there was considerable inconvenience in procuring sleep, the semi-erect attitude being one time most endurable, and lying very level at another time gave remarkable relief. He now lost flesh, became most debilitated, and the difficulty of breathing became very urgent at times. Examination by the laryngoscope was all but intolerable; the epiglottis seemed healthy, and some ulceration was seen only in its immediate neighbourhood. The symptoms now increased in urgency; the constant cough, and the profuse expectoration, which increased very much at the later stage of the disease, were wearing the patient, and there was evident danger of rapid exhaustion from the urgency of the difficult respiration. On consultation, it was determined, notwithstanding the supposition that the ulceration had extended deeply, to open the larynx; which was done with temporary relief to the patient, but death supervened from exhaustion on the succeeding day.

A *post-mortem* examination showed the extent of the disease, and that it had extended, as it is too apt to do, from above downwards, commencing in the larynx and finally reaching the trachea, and, in this case, into the very bronchial tubes. The lungs were slightly emphysematous, the heart enlarged and soft, and the liver remarkably and characteristically diseased, having numerous gummata, both on the surface and in the interior.

As shown in the illustration, the entire larynx, trachea, and even a great portion of the bronchial tubes, were the seat of ulcerations, while a remarkable constriction and narrowing of the trachea had taken place from the continued glandular pressure caused by the deposition of gummatous material. This narrowing took place the more easily as the cartilaginous rings of the trachea were softened and diseased, and in some places, as seen at the extremities of the diseased cartilages, protruded into the tube itself.

This example of the late and permanent effects of the syphilitic taint, as verified by a *post-mortem* examination, is instructive, and shows the difficulty in foretelling how far the same vitiated action which diseases the upper larynx may not have extended to the deeper portion of the respiratory apparatus, or may, by its simultaneous deposit in other organs, cause death, quite irrespective of laryngeal mischief.

On examining the liver, it presented a remarkable appearance, but was natural in size and weight. The right lobe was enlarged, and on the surface there could be seen here and there small elevations, each about the size of a boiled pea or bean. On cutting into the organ, over a spot indicated by a firmish feel, these deposits were easily exposed. They were yellow, about the consistence of cheese, and had every appearance of the gummatous matter. The drawing taken the day after examination shows the relative size and appearance of the gummatous materials.

In this case, beyond the uneasiness in the region of the liver complained of at times, there was no jaundice or indication of any deposit. The right lobe was enlarged.

## EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

BY C. A. GORDON, M.D., C.B.,  
Deputy Inspector-General of Hospitals.

### CHOLERA.—(Continued.)

THERE has of late years existed a manifest desire on the part of non-professional writers on cholera to rob medical men, and more especially Army-Surgeons in India, of the credit justly due to them of having been the first to recommend measures for the prevention of the disease, which, although perhaps only partially acted upon when first recommended, have since been brought forward by so-called *Sanitary Reformers*, as if they were recent discoveries of their own. In the following remarks I desire to indicate some of the most important of the labours of medical officers in reference to the sanitation of the disease, for which purpose I consider the subject in the following order—namely :

(a) The origin and course of epidemics ; (b) As to the probable dependence of the disease upon certain meteorological conditions ; (c) Its probable connection or alliance with malarious diseases ; (d) Its effects upon the prevalence of the ordinary endemic diseases ; (e) Its connection with *epizootics* ; (f) How affected by drunkenness ; (g) Its favourite localities ; (h) As to the correctness of nomenclature regarding it ; (i) Means of prevention ; and (j) Regarding isolation and removal of the infected.

a. Official records in the Army Medical Office, Calcutta, contain numerous observations which indicate that many years ago it was known that cholera usually, but not always, occurred first in Lower Bengal, and thence progressed to the more inland districts. In 1831, the Inspector-General in his "Annual Report" records the circumstance

that a case of this disease happened on the 6th of April among some men of the *Buffs* who were proceeding by the *Bhagurutte* River from Chinsurah to Berhampore ; that on the 16th of the same month it appeared among the troops at Chinsurah, at Dinapore on the 5th of May, Benares on the 8th, and Ghazepore on the 12th, so that although its progress seems to have been by a series of leaps rather than uninterruptedly onwards, its general course was upwards along the course of the Ganges. Two years afterwards, namely in 1833, Dr. Burke wrote that the disease "usually travels with the last windward rains, and is apparently arrested along with them." He moreover mentioned that "it seems to make its progress along the banks of the Ganges, spreading itself inland from these." Indeed, so well understood had the fact become in 1838 of the progress of the disease from East to West, and of its occurrence at particular stations at definite periods of the year, that any deviation from the rule became subject of remark. Thus it is said that since the beginning of that year "it had prevailed more extensively at Calcutta than is usual so early in the year."\*

b. The fact that an outbreak of cholera is often checked by the occurrence of a thunder storm is generally recognised in India. It is alluded to in various official reports. It is stated to have had this effect when an epidemic of the disease, prevailed at Berhampore in 1829, and the circumstance is again alluded to in the Inspector-General's "Report" for 1835.† Unfortunately, however, this rule is not invariable. In 1845, cholera of a very fatal character occurred at Meerut among the 10th Regiment ; and similar outbreaks after an unusual continuance of easterly winds, and after unusually heavy falls of rain, were not only commented upon before and shortly after that date, but formed the subject of investigation by the late Cholera Commission of 1861.

c. When in 1831 this disease prevailed in epidemic form at Ghazepore, the circumstance was mentioned by the Inspector-General in his "Report" for that year‡, that an increase in the severity of intermittent fever at the same station was observed ; and with reference to the occurrence of a very fatal epidemic, which raged in 1833, Dr. Burke expressed his belief that it appeared to have been caused by malaria.

Dr. McLeod observed in his report for 1835, that "on the disappearance of cholera, fever of the continued form began to prevail to a considerable extent among the young and robust, attended by severe headache and high arterial action. The tissues of the eye and the skin were usually of a yellow colour, but there were no other symptoms present to lead us to the conclusion of the liver being deeply affected." "Gastric derangement," he adds, "was a very common symptom." In the "General Report for India," for 1844, we find the following remarks relative to an epidemic of fever which had during that year prevailed in the 29th Foot at Ghazepore—"The pulse, almost always weak and frequent, about 100. In some cases the prostration was extreme from the commencement, *closely resembling the collapsed stage of cholera*. There was certainly a curious affinity between these two diseases—a livid colour of the skin, a turgidity of the lips and fingers in the severe cases of the epidemic."

The Surgeon of the *Buffs* thus wrote of the fever which severely affected the men of that regiment in 1841 :—"In several cases of remittent fever of the worst type pain was complained of, chiefly affecting the muscles, usually of the lower extremities. In several other instances when the patient was considered as going on favourably, the train of symptoms suddenly, and generally without any evident cause, underwent a most unfavourable change, assuming many of the features of cholera ; the extremities and body being icy cold, with feeble or no pulsation at the wrist, and scarcely any at the heart ; great prostration ; urgent

\* "Report." 1836 to 1838.

† Page 34.

‡ Page 51.

calls for drink, frequently accompanied by muttering delirium." "These symptoms," Dr. Macqueen observed, "were more often observed in young men who had shortly before been in robust health; and, it may be added, no recovery took place in such instances."

I would also observe that in and prior to 1831, Drs. Searle and Stevens suspected that an analogy existed between cholera in the East Indies and yellow fever in the West; and that more recently, medical officers, who have served and witnessed those diseases in both countries, have in their reports alluded to the same circumstance in their phenomena.

d. A perusal of the reports on the state of regiments in Bengal for the years from 1826 to 1829, will suffice to indicate that army medical officers of that time were fully aware of the tendency which, during epidemics of cholera, the ordinary diseases of the country manifested to merge into that affection. Lest, however, I may be accused of simply dealing in generalities in this statement, I will give a definite instance: it occurs in the "Report" for 1829,\* and there Dr. Burke expresses himself in this way. "Cholera," he wrote, "like many epidemics whose history has been handed down to us, either modifies, changes, or, for a time, banishes the epidemics of the season or country." And here I would allude to one lesson that is to be obtained from this brief paragraph. It is, that the medical officers who wrote in 1829, were careful before expressing their own views to study the literature of the diseases regarding which it became their duty to write—an example I would strongly recommend for the adoption of some of their successors of the present time.

e. "It has often been observed," so wrote Dr. McLeod, "that during the prevalence of an endemic disease among the human species, the lower animals, and even fish generally participate more or less. This happened in a very remarkable degree in the month of March, 1829, when cholera morbus prevailed so extremely in the 49th Regiment, at the station of Berhampore in Bengal." He then goes on to advert to that epidemic, and thus continues: "It is a curious fact, and one worthy of record, that during the rage of cholera, a considerable number of fish of every sort and size to be met with in the large tank close to the barracks, sickened and died, or became perfectly powerless, floating on the surface of the water, so as to be easily caught by the natives." He further records the fact that "about the same time a distemper appeared among the dogs at the station, and prevailed to a great extent in a kennel of foxhounds," where it "carried off in a very short time the greater number attacked."†

f. I have already had occasion to allude to the evils which in India attend the distribution of money and bounty to soldiers, and especially to the drunkenness and riot which prevail at such times. Official reports inform us that under such circumstances cholera, in 1829,‡ broke out among the men of the 47th Regiment, then quartered at Berhampore, they having shortly before received their prize money for Ava, and that a similar occurrence took place at the same place among soldiers of the 14th Regiment after they had been paid their prize money for Bhurtore. In the same year cholera, in epidemic form, attacked the men of the *Buffs*, stationed at Bhaugulpore, immediately on those who had volunteered from the 59th Regiment had received their prize money for Bhurtore. We learn that much drunkenness prevailed there from the time those men joined the *Buffs*, and that the soldiers exposed themselves recklessly to the sun, roved about in search of liquor, and often bathed in the adjoining river, regardless of the dangers they thus incurred.

g. The great degree of liability of detachments of troops proceeding up by the river Ganges to be attacked by cholera, was noted so long ago as 1829.¶ Dr. Burke, in

describing this occurrence, observes that "during an epidemic of the disease from which the *Buffs* suffered while travelling up by river route," and to which allusion has already been made, "the attacks were most severe when the boats remained during a night upon a low-lying muddy bank; and less so when under high and abrupt banks. Another circumstance recorded on the same occasion is not without its value now, namely, that the guard of natives attending the regiment suffered less from the prevailing disease than the soldiers.

The circumstance was also early noted that troops occupying ground floors of barracks were more susceptible of the disease than those upon upper storeys. Thus, on the occasion alluded to, when cholera occurred in the 49th Regiment at Berhampore, we are informed that "the soldiers and married families lodged in the lower floors were nearer to, and more intimately connected with the poison producing the disease" than those more elevated, "presuming," as the report goes on to observe, "that the poison emanates from the ground."\* Another point connected with this formidable disease, which we find alluded to in the older reports, is the liability of soldiers, while undergoing treatment in hospital, to become its subjects. This liability was specially alluded to in the report on the 49th Regiment, when, while quartered at Hazarabagh in 1838, the men of the corps became subjected to it, "a larger proportion of the men in hospital" being on that occasion seized with the disease, "than of those in barracks."

h. Some recent circumstances have induced writers to express an opinion that many cases which, in former days, were recorded as cholera, were not of such a degree of severity as to constitute what would now be only described as of that disease. It is argued, on the one hand, that the medical officers of the times to which in these notes I principally refer, were less cautious in the phraseology they employed in describing the disease than those of more recent days have become; and also that some, in order to demonstrate the success of particular modes of treatment advocated by themselves, were induced to include among their cases those that would not now be described as cholera.

That such imputations should be made without the most ample evidence that grounds exist for them, speaks little in favour of the medical officers who gave expression to them. Perhaps, however, it will be well if I, on this occasion, simply give a few references to what is recorded on these two points. With reference, then, to the question of nomenclature, we find Dr. Burke, in 1828, quoting from the report† of Dr. Sandham, of the 11th Light Dragoons, expressing himself to this effect:—"Every case attended with vomiting and purging should not be termed cholera, or, at all events, might sometimes have *modified* added to it." Again, the surgeon of the 44th Regiment, in his report for the same year,‡ makes the remark that "it is not his intention to insinuate aught against those who have boasted of their success in cholera, but he knows that none which were not indisputable cases of spasmodic cholera are entered under that head in his return."

These remarks, I submit, indisputably show us, that if in some instances there may have been a certain degree of want of precision in the application of the term "cholera," our superior medical officers, whether in departmental position or professional attainments, observed an amount of precision in the manner of applying the term not exceeded by their most advanced brethren of the present day.

And so also was it with the second class of cases to which I refer, namely, those where some medical officers, in order to magnify the success of particular modes of treatment, did not at all times observe strict care in designating as cases of cholera those to which the desig-

nation was really applicable. It may be assumed from the nature of the comments which I am about to quote, that then, as in more recent times, the medical officers who wrote and spoke with the greatest amount of confidence of the success of their particular methods of treatment, were often those whose sphere of observation, and of action, was the most limited. It was of such that Dr. Sandham thus wrote, in 1828\* :—"It is somewhat vexing," he remarked, "to see some speak so confidently, and who have seen but little of the disease, except among natives, in whom," he adds, "I have generally found it tractable enough." Dr. Sandham well knew what was wanting, in some cases, at least, in order to rectify the views of such medical officers. "The care of a very few Europeans would soon put them right." And, doubtless, so it would.

It is, in fact, tolerably clear that so long ago as the time to which I here refer, the impression had begun to be proved that the rates of mortality in outbreaks of cholera, were really much alike, whatever may have been the plan of treatment followed, while the recorded success of some methods was probably more apparent than real. That this impression gained strength the longer the attention of superior medical officers was directed to it is apparent in the writings to which we have access; thus, for example, Dr. Clarke, when writing on the subject of cholera fifteen years afterwards, namely, in 1843, found himself driven to remark that "the ratio of deaths to recoveries from this terrible scourge cannot be estimated short of fifty per cent;" and, he adds—"I fear we must be compelled to acknowledge that little advance has been made in our treatment of this disease, from its first appearance in India to the present hour; certain forms of practice have been lauded as almost specific in their effects, which have been found, when employed afterwards during the period of the epidemic, totally unavailing."

Were we to believe what has of late years been said and written, we should be inclined to look with horror and contempt on the culpable ignorance displayed by our older army medical officers in regard to the precautions that were most likely to be successful against the onslaught of cholera. If, indeed, my readers have not already made up their minds on this subject—adverse, of course, to the claims of my departmental brethren—let me be permitted to solicit their attention to the following brief extracts from official reports which bear upon this question :—"It is reported that so long ago as 1830,† "during the prevalence of cholera, health inspections of the troops were made twice daily, and no men were discharged from hospital until perfectly recovered." In 1833, again, it is stated that among the measures adopted to check the spread of the disease was this, that "the stuffing of the bedding of the patients in cholera was destroyed, the bedcases washed and fumigated, as likewise the store in which they were kept;" and we moreover find it stated that "after the first thirty cases, no bedding was served out to those admitted, except such as could be washed"—an arrangement, let us add, which, dictated in a parsimonious and unworthy spirit, inflicted much discomfort and personal injury upon the men who were subjected to it.

In this year also, Dr. Daunt, Surgeon of the 44th Foot, "did not fail to adopt every measure that might contribute to the prevention and extermination of the disease, as well as to the best mode of cure, and to the comfort of the sick." Among others adopted on this occasion, we learn that the barracks in which the disease appeared were successively vacated—"the walls thoroughly scraped, and the whole barracks thoroughly cleaned and white-washed." It is moreover added that "if the season of the year had been favourable, an encampment at a distance from cantonments would have been recommended; but as it was, the weight of argument was considered to be against the arrangement."

## NOTES OF MIDWIFERY CASES.

By J. M. HYSLOP, M.D.,

Late Professor of Midwifery, Grant Medical College, Bombay.

*(Continued.)*

Nov. 28th, 1863.—Called to hospital at 1 p.m. to see a woman in her first labour, which commenced two days ago; pains strong; liquor amnii escaped yesterday. On making a vaginal examination, a thick and strong band was felt stretching across the vagina transversely. Presentation could not be made out; rectum cleaned out by an enema.

As there was no probability of the obstruction going away, my colleagues agreed with me that it should be divided. This was done; the left foot was then found presenting; this was brought down and delivery effected, but a large opening was found between the vagina and rectum; placenta thrown off immediately; child was premature and dead; the woman left the hospital in a few days, and her after history was not known.

January 26th, 1864.—A middle aged woman in her third labour for two days. Left hand and cord protruding from vulva; patient's condition bad; os soft and well dilated; a foot was brought down and child turned, but craniotomy had to be performed to effect delivery; did well.

March 27th, 1864.—Hindoo woman, æt. thirty, first pregnancy. In labour some days. Considerable constitutional disturbance; pains ineffectual; head impacted at brim; craniotomy performed; the bones constantly gave way, and the head was not extracted till the hook had been fixed in the right orbit (internally). In extracting the head the neck gave way; the hook was then with difficulty fixed in the right axilla, and traction made until the body was torn. The child, a male, had been dead for some days; the abdomen and scrotum distended with gas; much very offensive discharge from uterus; placenta not expelled for thirty-seven minutes after the fœtus; perineum much torn.

April 1st.—Has had fever and offensive discharge, but to day is well, and at her own request is discharged.

March 31st, 1864.—Half-past eight a.m. A young woman in the sixth month of her first pregnancy. It is been in labour for some days. Arm was presented and had been torn off; parts swollen; os puffy; abdomen tender; pulse very quick; urine drawn off, and twenty-five minims of tincture of opium given, and in an hour the fœtus was expelled.

April 4th.—Doing well; recovered rapidly.

April 4th, 1864.—Called at 8 a.m. to a woman just admitted, in her first labour for four days, child's arm protruding from vagina since yesterday; pulse 100, quiet. Evisceration was performed and version effected with difficulty. Head would not pass the brim, it was perforated, and delivery completed. Child a male. Brim of pelvis small. Did well.

August 21st, 1864.—7 a.m. A young Jewess, first pregnancy, in labour since yesterday morning. Head in pelvis, forehead to pubes; is said to have had four convulsive fits, one of an epileptic character; has never had fits before; feet anasarca; patient quite sensible; foetal sounds not heard; craniotomy performed, and child extracted with difficulty, owing to smallness of pelvis; placenta extracted after half an hour; after delivery the fits continued with stertorous breathing till 3 p.m. Cold was applied to the head, a blister to the neck, and sinapisms to the legs, and a diuretic mixture ordered.

September 8th.—Had had fever, but is now better, and wishes to go home. Discharged.

August 21st, 1864.—9 p.m. A middle aged woman, mother of several children, in labour since 3 a.m. The first of twin children born two hours ago. Arm protruding from vulva; uterine action smart; and uterus embracing the fœtus tightly; with great difficulty a knee was had hold of, and even then version was difficult;

child dead; placenta expelled immediately after the child, along with a portion of the other placenta; the remaining portion was extricated with the hand. Recovered.

October 10th, 1864.—A Parsee admitted at half past seven, a.m.; has had several children; said to have been in labour for three days; pains strong, and bearing down; skin cool; pulse good; both hands and umbilical cord of foetus protruding from vagina. After consultation with my colleague, Dr. Peet, it was determined to eviscerate the foetus, and then extract. The chest was perforated, and the blunt hook introduced to break up the contents of the thorax and abdomen. On withdrawing the finger, a loop of intestine escaped from the vagina; there was, no doubt, in the minds of two colleagues who were present, and myself, that this was the intestine of the mother as it was the usual size of the small intestine of an adult. Delivery was effected by turning after evisceration, and then it was found that the prolapsed intestines was that of the foetus. The uterus contracted well, and placenta was soon ejected, and all was completed by half-past eight o'clock. At ten, the Matron, who had never left her, observed that her countenance was anxious, and pulse very feeble; she called the apothecary, who gave her stimulants, but she died with a slight convulsion, at twenty minutes past ten a.m.

The Matron states that the woman never spoke after the operation, but pointed to her chest as the seat of pain. She says that the uterus was *not very large* at the time of death, but I fear this must be set down as a case of death from internal hæmorrhage.

## HEATED APPLICATIONS TO CATHETERS AND BOUGIES.

By R. HANSLIP SERS, M.R.C.S.

In the lubrication of catheters, &c., castor oil, from its viscid nature, continues to hold its vantage ground. Authors have affirmed concerning it that it loses its viscosity just at the proper time as it becomes warmed by the instrument and the urethra. The removal of all preventible sources of irritation to the urethra is imperative. Hence it may be inferred that it is advisable to reverse the order above mentioned, and consequently to warm the instrument and the urethra by the oil. It is my custom to use thickened oil, heated to an agreeable warmth (the bottle containing the oil, &c., is placed, during a minute or two, in close proximity to the fire), whereby the operating fingers and the catheter, even in the coldest season, may be instantly brought to any desirable temperature. To roughen a catheter by holding it before the fire, then to apply half frozen oil, and subsequently trust to a little friction through a cold hand in order to warm oil, catheter and fingers is scarcely likely to achieve the object in view.

Finally, it is a mere waste of time to thoroughly warm a catheter either by friction or by contact with the skin and then well oil it with a frigid application. It is a physical law that the instrument must exceed in temperature the canal which it is about to traverse, otherwise it cannot be called warm with respect to that canal.

## Hospital Reports.

### KING'S COLLEGE HOSPITAL.

#### Removal of Tumour from Lower Jaw.

(By SIR WM. FERGUSSON, BART.)

SIR WILLIAM stated that the tumour had commenced to grow from the gum about two years since; he thought that

probably it was originally of a fibrous-cellular character, but that latterly it had degenerated a good deal. Had much increased in size, and as they now saw, occupied the mental space of the lower jaw. It was about the size of a hen's egg, and the skin covering had a red and unhealthy appearance. As soon as the patient was anaesthetised, Sir William commenced the operation by making a semi-lunar incision, which encircled the lower convex margin of the tumour, and the skin was then carefully dissected off the tumour from below and upwards. As soon as this stage was completed, Sir William, by a series of *dexterous surgical manoeuvres*, enucleated the tumour, and then by means of a saw and bone forceps removed a large portion of the lower jaw. The edges of the wound were then brought together, and dressed in the usual way.

Sir William was assisted by Mr. Henry Smith and the house-surgeon.

Sir William then stated that it was his practice, in cases of this kind, to endeavour to save some portion of the bone, the inner plate if possible, in fact, any part, and as a rule he was enabled to do so, as patients applied early, and there was not a great deal of disease of the bone. Here, however, a contrary state of things existed, which rendered it imperative on his part, though he was unwilling, to remove all the diseased bone, instead of making the operation, to a certain extent, a conservative one. Again, the class might have noticed that he had removed a portion of the skin; this was on account of the diseased tissue being so adherent to the healthy; nor did he consider much unsightliness would result on account of the elasticity of the parts. Now, as regarded the operation itself, the class might have noticed that the facial artery, just at the point it divides, had been cut through, and bled very profusely. Many surgeons would tie this artery at once, or after the operation had been completed. He had done neither the one nor the other, as from long experience he was aware that in a very short time after the artery had been cut it would retract and give no further trouble. Now, as regarded this and other kindred operations for the removal of a *portion of the lower jaw*, the older school of surgery had, with much obstinacy and perversity, opposed such operations as being unsuccessful, by reason of the *whole jaw* not being removed. An experience of thirty-five years in operation for the removal of portions of the jaw, together with the success he had met, was, he was glad to say, recognised by a large number of surgeons of the modern school, who now practised the principles he had so long and earnestly practised, and strenuously advocated.

#### Delegation of the Femoral Artery.

(By PROF. WOOD, F.R.S.)

THE case of popliteal aneurism, under Professor Wood, had been in the hospital about three weeks, and had been treated by *Coffe's* tourniquet, and the double-pad one of Signorini. It was somewhat unusual, Professor Wood said, to find popliteal aneurism in a man so young. At first the patient positively objected to pressure at all; however, by dint of talking to he submitted, and no doubt he was to a certain extent benefited, inasmuch as the pulsations in the aneurismal tumour were not so strong, and a change in the form of the tumour had taken place, which the Professor regarded as indicative of improvement, viz., there was *increase of length in the long axis*, and *diminution in the transverse*. The patient continued to improve till the 22nd of July, twelve days after admission, when Mr. Rocke, the house-surgeon, noticed that there was slight effusion of blood under the skin of the aneurism, and that the pulsation had increased. The Professor's attention having been drawn to this circumstance, he determined at once to operate.

*The Operation.*—The first incision made through the skin and superficial fascia was much smaller than that usually adopted by most surgeons, being scarcely two inches long. In the subsequent stages of the operation, the incisions were gradually lessened, though made in the same direction as the first, and were all made with light touches

of the knife only, no director being employed. On reaching the sheath, Professor Wood raised a very small piece of it, and by a series of little cuts or "touches" in a *transverse* direction, passed the director, and opened the sheath. He next passed a small probe under the artery, to disconnect it with the surrounding tissues; passed the aneurism needle under it armed with stout thread, and tied the artery. The time occupied in delegating the artery was *three minutes and thirty seconds*.

*Dressing of the Wound.*—The wound was then dressed in the following manner:—The edges were first brought together with three carbolized sutures, then two pads of lint were placed on either side of the wound, and kept in their position by straps of plaster passing from the outer to the inner side of the thigh. A putty poultice was then applied, the whole of the lower extremity wrapped up in cotton-wool and blankets, and the patient carefully removed to bed.

*Clinical Remarks after the Operation.*—Professor Wood observed that although the treatment by pressure has failed, still it had not been without its advantages in this case. He believed that while the treatment by pressure had been going on, the collateral circulation had been well set up, so that there was less fear of sloughing of the toes, &c., than if this preliminary treatment had not been adopted. Moreover, as such accidents as those he had just referred to were commoner in the lower than in the upper extremity, such preparatory treatment in cases such as these might prove of much benefit. As regarded the operation, although his first incision had perhaps not the conventional length, still there was sufficient room to work. Then, as he proceeded deeper, the incisions were decreased in size and more caution exercised, and the incisions were so arranged as to produce triangular or funnel shaped wounds, the apex being the opening of the sheath, the base the surface of the skin. If all the incisions had been the same length, you would have a square wound, and the matter would "bag." Dangerous, if not fatal results follow therefrom. Again, he was very careful not to open the sheath much, and to disturb the parts as little as possible as well; because, if the *vara vasorum* or nutritious arteries of the vessel are disturbed, sloughing of the artery may follow.

Now the class had observed that he dipped all the instruments employed in the operation in carbolic oil, as well as the ligature. He did this, as he believed, to a certain extent, in the antiseptic system, and moreover he thought the employment of the putty poultice would at least have this benefit, viz., that all air getting to the wound, would by the interposition of the putty poultice be purified. Germs he did not believe in. Again, the class had noticed that he had been careful to wrap up the leg immediately the operation was completed. He did this, as he believed that many patients in going from the operating theatre to the ward had the temperature of the limb so reduced by not being carefully covered up as to lead to serious complications hereafter.

"July 29th.—The patient has continued to do very well. There is a slight flush on the anterior surface of the thigh just above the wound. The pulsation in the tumour returned yesterday, but is slight in character. The limb and toes are comfortably warm, and the collateral circulation the Professor believes to be fully established."

"August 3rd.—A small abscess formed in the groin, and the matter made its exit by the original wound made for tying the artery. The man is now doing very well. The ligature came away on the twelfth day, and the patient ultimately left the hospital perfectly well."

## METROPOLITAN FREE HOSPITAL.

### *Cases of Epilepsy.*

(Under the care of Dr. C. R. DRYSDALE.)

CASE I.—Hannah Evans, æt. seventeen, has had about twelve fits—the first one commencing about a year ago.

Does not know the fits are coming on, except that she has "a nasty feeling come over her right eye, and when she looks at anything it looks red just before the fit." Loses consciousness sometimes for an hour, struggles and clenches her hands and jaws; when she wakes up has a bad headache, and feels sick and giddy, and goes to sleep. The first fit came on after being nearly run over in the street. She has fits of vertigo sometimes. Seen first, 10th October, 1871, when five grains of bromide of potassium were prescribed. Notes taken on several occasions in October showed that the patient was benefited by the medicine, and, on the 30th October she had not had a fit for six weeks.

CASE II.—Mrs. Taplin, æt. forty-five, has had fits for nineteen years past. Married 1843; in about two years after marriage, when pregnant, she was frightened by a woman saying that she had been nearly murdered by her husband. Next morning she had a fit, and had a dead child. No children born dead since that date. Has had several hundred fits. "Is taken all of a sudden, without warning; falls down like anyone dead; remains for twenty minutes to an hour or two without knowing where she is; struggles violently; goes to sleep after she gets better; no headache. Was sure to have a fit at monthly periods. Was treated since July with bromide first, and then iodide of potass. Has had a dozen slight fits."

CASE III.—M. Anne Nelms, æt. thirty-eight, married twice. Had her first fit seven years ago. Has had five children—one miscarriage. Her sister has been in a lunatic asylum. She came over very light-headed, and lost her senses for some time. Her second husband struck her on the head just before the first fit; has had about thirty fits altogether; loses her consciousness; foams at the mouth, struggles, and "bites her tongue dreadful;" has a headache when she recovers. Has felt greatly better (Nov. 10th, 1871) since taking ten grain doses of bromide of potassium three times a day since October 6th, 1871.

*Note.*—In these three cases, the patients all assigned fright as the cause of the first attack of epilepsy. In all three the bromide has been of service, which is much more than can be said in other cases, to be recorded at a future opportunity.

## I.—OXYGEN IN DISEASES OF THE LUNGS.

By HENRY N. READ, M.D., House-Surgeon, Long Island College Hospital.

(Continued.)

CASE XIII.—John Maurice, æt. twenty-two; United States; carman; admitted January 28, 1871. Has always been a strong, healthy man; no family history of tuberculosis. Three months ago was attacked with slight hæmoptysis, followed by cough, expectoration, loss of flesh and appetite. Has night-sweats and hectic; temperature 100°. Pulse nearly normal. Weight 138 pounds. Right lung gives usual signs of tubercular deposit at apex. Ordered four gallons gas, daily, with ol. morrh.; usual diet.

February 12th.—Commenced improving immediately after taking the gas; has gained two pounds. Coughs considerably. Lung much clearer; local subcrepitant râles detected; feels quite strong, and has good appetite.

February 26th.—Discharged to-day, and returns to his occupation. Lung quite sound on examination; is free from cough. Weight 147 pounds.

Result in Cases XII. and XIII. favourable. The absence of all hereditary taint and marks of "the hereditary consumptive"—the flat chest, incurvated nails, &c.—together with the general condition and appearance of the patients, renders it probable that the disease commenced in both cases as a pneumonic inflammation, the products of which, not being resolved, underwent caseous degeneration, and furnished the starting-point of the subsequent phthisis. The rapid recovery also strengthens this conclusion, the powers of the gas being especially marked in these cases,

CASE XIV.—Fritz Hanson, æt. thirty-three; Sweden; sailor; admitted January 23, 1871. Three years ago had an attack of bronchitis, which was not attended to, and, going to sea before getting well, the affection has become chronic. Dry and moist *râles* of all kinds heard over both lungs, and the peculiar wheeze of chronic bronchitis. Cough very troublesome, especially at night; is much worn by his complaint, and has no appetite. Blood is badly aerated, and there is slight emphysema of both lungs. Ordered two gallons gas, morning and night, ol. morrh. ʒss, twice daily, and *mist tussis* of Case II. Weight 133 pounds.

February 16th.—Improving; circulation much better, and has a good appetite. Cod-liver oil creates great nausea, and was stopped to-day. Cough still very bad. Gas continued.

March 9th.—Improving very fast; lungs are in a much better state. Cough much better. Weight 145 pounds. Gas continued. Spends most of his time out-of-doors.

April 8th.—Discharged to-day, and went to sea again. Weight 145 pounds, same as at last record. Lungs healthy, except the slight emphysematous condition mentioned; no cough.

CASE XV.—James Green, æt. twenty-three; United States; sailor; admitted February 4, 1871. Has lost two of his family "from some disease of the lungs." Was taken with cough a year ago, since which time he has had several hæmoptyses; the cough was not severe till a month ago, nor was he compelled to quit work till the present time. Within the last month, however, he has rapidly declined, is extremely emaciated, very weak, has exhausting night-sweats, and almost complete aphonia. Right lung gives all the physical signs of advanced tubercular deposit. Pulse 100 to 105; temperature 101°. Weight 116 pounds. Ordered three gallons gas, daily, ol. morrh., and the usual diet.

February 25th.—Has lost two pound in weight; no appetite; temperature 101° to 101½°; pulse 100. Coughs less, and sleeps better. Ordered one more gallon gas, making four gallons in all.

March 9th.—Slight general improvement, but no gain in weight; has a little better appetite, and sleeps well. Pulse and temperature as at last record. Night-sweats continue. Ordered quinine and acid; oil and gas continued.

March 22nd.—Is getting worse. On further examination, the *left* lung is found more or less consolidated at apex; no normal respiratory sounds heard in the right lung at all. Has lost five pounds in weight; hectic and cough very bad.

April 2nd.—Sinking fast; both lungs extensively involved; is unable to leave his bed. Treatment did him no good.

April 5th.—Died to-day.

CASE XVI.—Bernard Clark, æt. twenty-three; Ireland; porter; admitted February 13, 1871. Was attacked four days ago with pneumonia of right lung; has cough, rusty sputa, &c. Nearly the whole lung solidified, and respiration very laboured; face anxious; pulse 128; temperature 103°. States that he is of a consumptive family, and has spit blood on one occasion, but has enjoyed good health previous to this sickness; has been a very temperate man in his habits. The physician who had attended him previous to this sickness states that he has a slight tubercular deposit in apex of right lung, and the inflammation commenced in this case at the apex, and not at the base. Patient very weak, pulse feeble, &c. Ordered supporting treatment, with two gallons gas morning and evening, to sustain and relieve the dyspnoea. Warm fomentations to chest. Weight not taken.

February 15th.—Breathing better, and is not so restless; expectorates freely; temperature 100°. Has some appetite. Treatment continued.

February 20th.—Is improving rapidly; is able to walk about the wards. Lung is clearing up, though he continues

to expectorate a good deal. Has an excellent appetite. Pulse and temperature nearly normal.

February 28th.—Discharged to-day, entirely well. Lung clear, except at apex, where breathing is slightly exaggerated.

May 20th.—Saw patient to-day; says he "never was in better health;" looks well, and is at his work. This case was remarkable for the rapid recovery from the pneumonic condition.

CASE XVII.—Lawrence Dolan, æt. twenty-four; Ireland; mechanic; admitted February 24, 1871. Had lost a father and brother from consumption. Was in good health till last June, when he was taken with a slight cough; and, being examined at the time, says his physician told him he was "threatened with consumption." His health, however, did not suffer materially, although he had two hæmoptyses; and his cough left him after a short time. He has been dissipated in his habits, and in November last got on a spree, and continued on his debauch till Christmas, when, after getting wet, he was attacked with cough, fever, pain in side, spitting of blood, etc., which has continued to the present time. On admission to the hospital, he is extremely emaciated, very weak, has hectic, anorexia, etc. Both lungs are involved, and a large cavity is detected in right apex; the whole of this lung is badly damaged. Ordered four gallons gas, with ol. morrh., daily; usual diet; pulse 106; temperature 101° to 101½°. Weight 111 pounds.

March 1st.—No better; is very nervous from the effects of his drinking; no appetite. Disease seems progressing in left lung. Ordered anodyne at bed-time. Original treatment continued.

March 12th.—Is failing rapidly; the whole of the left lung is involved, and no normal respiratory sounds are heard in any part of the chest.

March 17th.—Died to-day, deriving no benefit from treatment.

CASE XVIII.—Thomas Frawley, æt. thirty; Ireland; labourer; admitted February 21, 1871. Attacked with cough, pain in side, &c., last August, but was not confined to bed; spat blood at that time. Cough has continued to the present, but has not quit work till now; has lost some flesh, but has no hectic. Left lung dull at base, dullness extending as high as sixth rib; left side somewhat contracted, and has pains through it. Expectorates freely; sometimes spits clear blood, at others the blood is mixed with the yellow mucus. Has no hereditary taint, and is in fair condition. Weight 126 pounds; pulse nearly normal; temperature 99°. Ordered three gallons gas, with ol. morrh., daily.

March 16th.—Improving slowly; eats and sleeps well, but continues, occasionally, to have hæmoptyses. Treatment continued.

April 25th.—Much improved; examination shows the lung almost clear.

May 28th.—Lung-sounds normal. Weight 134 pounds. Is in good health, and in fit condition to be discharged.

CASE XIX.—John Johnson, æt. sixty-one; Sweden; sailor; admitted February 22, 1871. Has had a chronic bronchitis for some years; is much worn down by the disease, and very weak; coughs incessantly, and rests very badly at night; poor appetite. Both lungs affected; *râles*, dry and moist, heard; some slight emphysema detected. Pulse and temperature normal. Weight 136 pounds. Ordered four gallons gas, daily; *mist tussis* of Case II.; ferri et quin. citrat. gr. v. *ter die*. Good diet; counter-irritation to chest.

March 20th.—Improving; cough much less troublesome, and sleeps well.

May 1st.—Continues to improve; lungs in better condition; only dry *râles* heard.

May 26th.—Lung-sounds nearly normal; weight 152 pounds. Sleeps well, and is in good general condition. Is ready to go to sea again.

CASE XX.—Gustave Hatton, æt. twenty-two; Sweden; sailor; admitted February 20, 1871. Was attacked with pneumonia three weeks ago at sea; has cough: rusty sputa, &c. Base of left lung involved; inflammation in resolving stage; dulness on percussion, extending as far as fourth rib; moist *râles* heard. Is weak and exhausted; laboured respiration; temperature 102°; skin hot; pulse 118. Has been a healthy man, and has no hereditary taint. Ordered four gallons gas, daily; as a general stimulant, quinine and good diet.

March 21st.—Improving; lung much clearer; has some pain in side, and night-sweats. Ordered acid. sulph. arom. gtt. xx. *ter die*. Treatment continued.

April 21st.—Discharged to-day; lung clear; general condition good. Regards himself as well.

CASE XXI.—Francis Smith, æt. thirty-three; United States; sailor; admitted January 16, 1871. Has never been a strong man, and inherits tuberculosis. Two months ago, at sea, had a pneumonic inflammation of right lung; cough, pneumonic expectoration, &c. He had no treatment, and was much exposed. Present condition very poor; right lung dull over most of its surface; respiration tubal; mucous *râles* heard, except at base. Is very weak and anæmic. Pulse 90; temperature 99°; weight 126 pounds. Ordered three gallons gas, daily; ol. morrh. with ferri hydrophosphites. Usual diet.

February 16th.—Slight improvement. Weight 130 pounds. Cough and expectoration still troublesome. Ordered *mist. tussis* of Case II. Treatment continued.

April 10th.—Not improving; has lost the flesh he had gained, and five or six pounds besides. Left lung has become involved; dulness with bronchial respiration, and mucous *râles* heard at apex. Ordered one gallon additional of gas, making four in all.

May 12th.—Patient declining. Both lungs have become hopelessly diseased. Diarrhœa has set in, and he cannot leave his bed.

June 1st.—Died to-day.

I have briefly recorded the foregoing cases, and now submit them to the profession, for the purpose, mainly, of showing the action of oxygen gas, *in conjunction with cod-liver oil*, in diseases of the lungs. In some cases, it will be seen, no good results were obtained; in others, the improvement was very marked. It will be for the profession to judge of the adaptation of the treatment to the particular cases reported. It will be observed that, while no specific effect is claimed for oxygen, yet it has been found a most admirable *adjuvant* to the cod-liver oil, and the usual routine treatment in phthisis pulmonalis. Especially has it been found useful, *in conjunction with the oil*, in those cases of phthisis where the patients, either from inability or from the state of the weather, are unable to go out-of-doors. In the cases of acute pneumonia in which it was given, it invariably had the effect of easing the laboured respiration in the early stages, and of promoting the resolution and absorption of the inflammatory products in the latter.

Case XVI. is an instructive and illustrative one of this class. This patient had an acute pneumonia in a lung evidently already tuberculous. This will be recognised as a very grave and uncompromising condition of affairs—a condition which often terminates in what is popularly known as “galloping consumption”—properly termed by Condie, of Philadelphia, “*tubercular pneumonia*.” The temperate habits of the man, and the early commencement of the treatment, must, of course, be taken into consideration in the case. The result was complete and rapid recovery.

Case XVII. was analogous to this; *i.e.*, the patient had pneumonia in a lung in which tubercles existed previously. But the dissipated habits of the man, and the neglect of treatment, had allowed the disease to make such progress, that the treatment, when administered, had no effect in checking its rapid advance. The man sank soon after his admission to the hospital. The beneficial action of the gas was marked in the troublesome affection, *chronic bronchitis*; increase of appetite, weight, and diminution of the paroxysms of the cough, usually following its exhibition.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, DECEMBER 13, 1871.

### ORIGIN OF THE ILLNESS OF THE PRINCE OF WALES.

It is by no means surprising that the deepest interest should have been excited when the Heir to the Crown was struck down with typhoid fever; and, therefore, the flood of articles on the subject that has flowed for the last few weeks was to be expected. It is to be hoped they may do much good by directing urgent attention to the sanitary defects that prevail throughout the country. We do not mean to assert that sanitary improvements will ever eradicate whole classes of disease, as not a few expect—at any rate, in the near future. But it cannot be too frequently repeated that thousands of lives are constantly lost through inattention to these matters. Nevertheless, it is going too far to assume that in any case it is an easy matter to assign the cause of the disease.

We are told, indeed, by some of our friends who have visited the places, and their views are confirmed by correspondents, as well as by writers in other journals, that at Scarborough and at Sandringham too, there were serious defects—in the one case, the air being poisoned by sewer gas; in the other, the water contaminated. Those who believe that typhoid is usually propagated through the air, have fixed upon the Prince of Wales's bedroom at Scarborough as the origin of the disease, because it communicated with the water-closet. But a similar arrangement exists in thousands of the best houses in London without giving rise to typhoid. Of course, it will be said that there was defect; but it ought not to be forgotten that there was no offensive smell; and to assert that sewer gas penetrated a certain room, and poisoned the Prince and the Earl of Chesterfield, who occupied it after the Prince left, but gave no indication whatever of its presence by its odour, is to say more than most people will readily believe.

We shall no doubt be told that a certain specific contagium is the exciting cause of the fever—that this might have passed into the Prince's room, without warning by its smell; but we submit, if it be granted that typhoid

can only be propagated by a specific contagium, the advocates of this hypothesis are not justified in expecting us to believe that this contagium would pass into the house when sewer gas would not. In spite of all that has been said and written, we are entitled to say the evidence is not sufficient to justify the conclusion that too many have drawn. Besides all this, we know that men exposed to emanations from sewers and cesspools do not fall victims to typhoid in greater proportion than others.

Moreover, there are not a few who deny altogether that the disease can be spread through the atmosphere. The water theory is equally consistent, but it is equally difficult to prove or disprove. At Scarborough all the Royal party, we are told, drank the purest water. As to the Bristol water, on which some desperate adherent of the water hypothesis would cast blame, it is not to be forgotten that it has been in use for years in the Lodge itself, and in many other places, and was never before suspected.

We turn to Sandringham, then, and there we are repeatedly told the water of the Hall itself is of very doubtful purity, and some of the property of the Prince is supplied from a well that certainly contains organic matter—although it is of high repute in the neighbourhood for its excellent quality. Besides this, one of the Royal grooms, who never went to Scarborough, has been down with the fever. There is apparently, so far, just as much probability that the Prince contracted the fever at Sandringham as at Scarborough.

We might leave the question here, and let the advocates of the two hypotheses fight it out; but there are other issues equally important.

It is quite conceivable that other entrances for fever are as common as, or even more common than either, air or water. The great difficulty is the impossibility of showing that none of those attacked by typhoid breathed a certain air alone, or partook of a certain water supply alone. Thus, reference has been made to the offensive receptacle of the middens and dust-carts by which the Royal party often passed, and which smelt so badly as to make the Duke of Beaufort feel sick. But we do not hear that the carters who take the filth-carts to the place, and empty them six or seven times a day, have been seized with the same form of disease.

Again, we are told by a correspondent, that the Royal party were shooting for days over a most pestilential district; but if the air of this was the cause of the fever, why did it only affect the Prince and the Earl of Chesterfield?

The water theorists would probably venture a guess that the two sufferers on some occasion or other drank a glass of water, out of the usual course, and thought no more about it. It is obviously impossible to assert that so simple an act might be quickly forgotten; but surely water so poisonous as that is acting on everyone who takes it. One would hardly suppose the Prince, or anyone else, would take water from any stream on the "pestilential swamp" where they were shooting, though this might have possibly occurred. It would be more likely to occur on the visit to Sandringham or to London.

So far as argument goes, we might just as well say the disease was produced by food as by water or air. Many distinguished authorities think that food, in a certain condition of decomposition, is capable of producing typhoid. Fish is, if not fresh, particularly unwholesome—and what do we know about game? It is often taken as a delicacy

in a condition which is certainly one stage of decomposition.

It would be easy to go through a number of other supposed causes of typhoid, and show how very inadequate are all theories to account for all the facts daily met with in practice. How difficult then must it be to arrive at certainty as to the origin of the Prince's disease.

Without any wish to depreciate the work of those who have set themselves to solve the question, we confess that the evidence at present adduced does not justify the conclusions that have been so positively put forward.

We do not deny that foul air and contaminated water are both dangerous to health. We have, over and over again, urged the necessity of attending to these things, and it is to be hoped that the nation may become henceforth more alive to all sanitary questions, and more determined to carry out sanitary reforms.

#### FRAGMENTATION OF BULLETS IN GUNSHOT WOUNDS.

THE principle of the transformation of forces has found, according to a note communicated to the Paris Academy by M. Larrez, an application in surgery which is considered to explain certain effects of projectiles. The author of the communication states, that when one of these bodies, driven with great speed, strikes an obstacle which is capable of arresting its progress, the motion with which it is animated is converted into heat, and the missile increases in temperature. The degree of temperature which it may thus acquire may be sufficient, in the opinion of M. Coze, the Strasburg Professor, to produce fusion. Two results would accrue from this—firstly, the fragmentation of the ball, and secondly, a burn more or less considerable in extent, and in the effects on the tissues. It would seem under these circumstances as if the wound had been produced by an explosive ball, and it is maintained that this fact, being insufficiently known or appreciated, gave rise in the late war to the reciprocal accusations made by the belligerents, as to the employment of means which had been prohibited by the laws of international convention.

In the *Gazette Medicale de Paris*, of 18th of March, 1871, this question was discussed, and M. Nicaise then arrived at conclusions almost similar to those of M. Coze; yet, while he admits that the ball may be heated by its impact against a bone so much as to lose its cohesion, he does not think that it is possible that the metal might be fused, and thus a true burn might be added to the lesions caused by the contusion.

However incredible all this may appear, so far as it affords any explanation of surgical phenomena, it may be assumed that the results detailed by M. Coze and M. Nicaise are not put forward without strong probability on scientific grounds. Perhaps the results arrived at by these authors may afford something in the way of explanation of the difficulty of finding the ball in the Kelly case, a difficulty which is supposed to have induced the jury to arrive at the extraordinary conclusion embodied in their verdict.

#### SCOTLAND.

EDINBURGH.—The first meeting of the Royal Society for the present session was held on the 4th inst., the opening address was delivered by the President, Sir Robert Christison, Bart.

**THE SYME SURGICAL FELLOWSHIP.**—The sum obtained for the endowment of this Fellowship amounts to £2,500, which will yield about £100 per annum.

**EDINBURGH MEDICO-CHIRURGICAL SOCIETY.**—The following gentlemen have been elected office-bearers of the Medico-Chirurgical Society of Edinburgh:—President—Dr. P. D. Handyside; Vice-Presidents—Dr. Matthews Duncan, Professor Lister, and Dr. Robert Paterson; Councillors—Dr. James Frazer, Dr. John Chiene, Dr. C. H. Groves, Dr. Wyllie, Dr. Gordon, Dr. John Sibbald, Dr. J. R. B. Cunynghame, and Dr. William Craig; Treasurer—Dr. George W. Balfour; Secretaries—Dr. Argyll Robertson, 40 Queen street, and Dr. Claud Muirhead, 7 Heriot row.

FROM the increase of small-pox in the city, and the inadequate accommodation in the small-pox hospital, it has been found necessary to open a portion of Watson's Hospital for the reception of new cases. This arrangement will not interfere with the operations of the workmen who are now busily engaged upon the foundations of the new Infirmary.

**DUNDEE.**—Miss Baxter, of Balgavies, desirous of being associated with her brother, Sir David Baxter, Bart., in the erection of the Convalescent Hospital, has contributed £5,000 towards the building and its endowment.

**ABERDEEN.**—Dr. Harvey has resigned his appointment of senior-surgeon to the Royal Infirmary.

## Notes on Current Topics.

### The Elberfeld plan of dealing with Pauperism.

THE Local Government Board has issued its report of the inquiry held by Mr. Doyle, one of the Poor-law Inspectors, and the British Consul in Saxony, into the system of poor-law relief in Elberfeld. This system in a few years succeeded in reducing the rate of pauperism from 8 to 2 per cent upon the population and has naturally attracted the notice of poor-law reformers. The Elberfeld system is no doubt thorough and a town of 50,000 inhabitants taking upon itself the solution of the pauperism problem is an attempt that will please many. But Elberfeld differs very much from any English town. Here the Poor-law administration throughout the country is regulated by one central authority. In Elberfeld there exists an independent local administration. The enquiries tolerated at Elberfeld would alone conflict with all our notions and cause a terrible outcry. Not only must the pauper seeking relief show that he has resided at Elberfeld twelve months and state where he resided before, but whether he reported himself to the police. His entire family has, moreover, to be placed under the penalty of degradation because of the misconduct, or misfortune of a single person. To effect this every applicant for relief is bound to give not only his own name, but also the name of every member of his family, his religious profession, his birthplace; "the state of health of each member of his family, his occupation, the name of his employer, his average weekly earnings, proved if, possible, by a voucher;" he must declare "whether the family leads a moral and honest life," specify "which of the members does not, whether or not the children are sent to school,

and where; the name, dwelling, business, and circumstances of surviving parents, parents-in-law, and grandparents, as well as of the children not living with the head of the family." In addition to this information, the visitor is to ascertain, as far as he can, and report "the causes of the pauperism of the applicant." It is obvious that this effort to crush pauperism in Elberfeld would find favour in this country where it would be thought sure to crush utterly the paupers as individuals. The Elberfeld method as set forth in Mr. Doyle's lucid and interesting report of his recent visit to Prussia is, however, worthy of study.

### Nothing New under the Sun.

It appears now that the pre-Adamite man—at least the American branch of him—knew all about what we have been deluding ourselves was the *modern* art of war, for according to the *Halifax (Nova Scotia) Express* of the 20th ult., a four-pound cannon ball was found in a lump of coal taken from a depth of 150 feet below the surface of the earth, at the Acadia Coal Mine, Maccan, Nova Scotia.

### The late Dr. Miles.

WE regret to announce the decease of Dr. Miles, of Heavitree, at the age of seventy-one. He was formerly surgeon to the Exeter Dispensary. He was honorary officer to the Royal Humane Society for Devonshire, and very highly esteemed in the large circle in which he moved for his charity and philanthropy.

### The Queen's Hospital, Birmingham.

THE *Birmingham Gazette* states that the foundation-stone of the new building in extension of the Queen's Hospital was laid last week by Lord Leigh, with Masonic honours. The Freemasons of the town assembled to support the Provincial Grand Master, Lord Leigh. The Masons formed one procession to the site, which adjoins the Queen's Hospital; and the working men, Foresters, Odd Fellows, Good Templars, &c., another. In the afternoon a luncheon took place at the Great Western Hotel, and a *soirée*, at which Mr. G. Dawson gave an address was held at the Town Hall in the evening.

### Modern Therapeutics.

IN the course of his able address at the meeting of St. Andrew's Association already mentioned in the *MEDICAL PRESS*, the President, Dr. Day, of Stafford, adverted to the progress of medicine, which he regarded with hope and confidence. The recent advances in medicine and surgery were spoken of as illustrations of what had been done, and might be expected. On therapeutics Dr. Day said:

"Three remarkable progressions seem to my mind to distinguish modern therapeutics. The first consists in the study of the action of medicines by the investigation of the physical characteristics of each medicinal substance; the second consists in distinguishing the special action of different remedial substances on particular parts of the living organism; and the third consists in bringing the art of prescribing to the utmost simplicity, so that when we prescribe we know precisely on what we wish to rely for the good we would secure. All these methods of improvement hang closely together, and yet they are often

distinctly pursued, not only by different men, but by men of diverse modes of thought. They are all good and productive of the best influences. It would be incredible to our forefathers to hear that we have men now, who—if you give them a chemical substance and tell them, this substance is composed of the following elements, it is of this specific weight, it is of this reaction, it is of this solubility, and it has certain other physical qualities therewith named—will tell you, in return, with an absolutely near approximation to the truth, what will be the physiological action of the said substance. Yet this is an accomplished fact, and, in the matter of those agents we employ to relieve pain, it has been one of the most fruitful means of the development of the triumph of human art over human suffering; a development belonging truly to the whole Christian era, but most to this latter-day section of that marvellous testimony of 'the ways of God to man.'

"Equally strange would it be to our forefathers to hear that we can now predict where a medicine shall, to speak plainly, go into the organism, and on what it shall act. Yet, in the case of some of our most potent agents, such as arsenic, nitrite of amyl, woorali, we know, when we give them, what will be the seat in which their influence or force will be expended, as well as the nature or quality of that influence.

"Finally, to the most distinguished of the older prescribers how strange it would be to tell them, we give up that long list of agents that constituted your favourite formulæ; we are content to try one agent at one time; and as to your method of putting your medicines into the body by the stomach only, we, in our day, wise as serpents and gentle as doves, put them in by the skin if we like, with a sharp tooth, or instil them in the vapour by the lung; so subtly, that the administration is all but unperceived. Yet this, too, is daily done, and with a successful result undreamed of by the earlier pilgrims of medical progress, and certain amongst the historical steps of our time to remain."

### Treatment of Carbuncle by means of the Hypodermic Syringe.

CARBUNCLES according to the "Georgia Medical Companion," are most safely, humanely, and more regularly treated, as follows:—Introduce the canula of a hypodermic syringe into the centre of the tumour, draw out the piston, and with it will come pus, if any. The syringe is to be removed from the canula, and emptied, the canula left in, and the syringe replaced to the canula again, and the piston withdrawn, as before, as long as pus follows. When all the pus is out, withdraw the canula and apply on the tumour, externally, with a brush, the following:—

|                    |           |
|--------------------|-----------|
| R. Collodion.....  | ʒj.       |
| Castor oil.....    | gtts. xx. |
| Carbolic acid..... | grs. v.   |
| Tannin.....        | ʒi.—Mix.  |

Several applications are to be made, one after the other, so that a good outer covering is obtained at once.—

### Habitual Drunkards.

THE discussion introduced by Dr. Swete, at the St. Andrew's Medical Graduates Association, may be mentioned if only for the sake of expressing surprise that he should fully endorse the sensation statements of the *Saturday Review* as if they had been a record of sober facts. Difficult as it is to deal with drunkards, there is a strong wish to do something, and the feeling of the meeting appeared to us to be in favour of Dr. Dalrymple's proposals.

### The Dublin Pathological Society.

WE understand that the reform movement in the Dublin Pathological Society, which was to have effected a rejuvenation of the Society has, for this year at least, come to a miserable end. As we stated last week, a meeting of the members, with all the appearances of enthusiasm about it, was held, to decide what the extent of the reform programme was to be. The aspirations of the meeting were nothing very lofty, and they decided to ask only that the Society should elect its Council, and that the meetings of the Society should be held under such circumstances as to allow the communications to be listened to in comfort, and discussed, if necessary. This gentle revolution was to have been completed on Saturday last, but, although the meeting was very largely attended, and seemed ready to approve some little amendment of the existing system, the reform representative abandoned all his positions almost without a blow in their defence, and the limits of the resolution, never too wide, were narrowed to a laughable *anti-climax*, which had better not be mentioned as a concession to the Reform party. It was decided, *nem. dis.*, that the Society should continue to meet between day and night in the afternoon; that the communications, when read, should be put under the table without question or discussion; and that the proceedings of the Society should continue to serve for a course of lectures for the student. The only point achieved by the "Tennis Court" party, was that three councillors should be rotated out of the governing body each year. It is right to be thankful for small blessings, homœopathic though they be. Let us hope that the members of the Society who long for the free air of open discussion and unfettered election will not be expected to subsist long on so microscopic an amount of relief.

### Dogberry on Post-mortems.

THE Clerk of the Peace for Middlesex thinks that a *post-mortem* examination for a coroner's inquest is "a very improper application of the public money," and a Mr. Turner, a Middlesex magistrate, said, "if such a state of things continued the magistrates must communicate with the Home Secretary, with a view to putting a stop to it." Bumble always was an advocate for the ready method of finding verdicts on the vile bodies of dead paupers. It would be a cheap process, and no doubt quite good enough for such purposes, if the coroner would tell the twelve wisecracks whom the law selects to decide on abstruse pathology, what the person died of, and if they would not give trouble by (like the engineer at the Circumlocution Office) "wanting to know" anything about the matter. Perhaps the Home Secretary may think that the public wants to know the reason of suspicious deaths, and may not agree with the Middlesex magistrate that the cheap and pleasant system is not always the best.

### The Visiting List.

THE twenty-sixth annual issue of the "Physicians', Surgeons', and General Practitioners' Visiting List," being that for the ensuing year, is already published.

The publishers have once more been able to add an improvement. Not only are the new postage rates given as we might have expected, but they have extracted from Squire's "Companion to the Pharmacopœia," a table of doses, which can, therefore, always be found in the pocket of those who are wise enough to carry the "Visiting List."

### Inebriates.

THE cure of Habitual Drunkenness by the aid of legislative restraint, an object with which this journal warmly identified itself long before its attainment came to be regarded as a possibility, was exhaustively discussed last week by the leading speakers of the St. Andrew's Graduates Association. The opinions expressed, and the action contemplated by the association speak loudly of a growth of feeling in favour of Inebriate Asylums within the last year or two which, if its development proceed at the same rate, will no doubt raise up for us a system of control which will constitute one of the greatest philanthropic attainments of the day. If one may judge by the utterances of the speakers in the association, the medical profession has passed the *rubicon*; has got over their natural hesitation to regard an insatiable drunkard as a lunatic, and deal with him accordingly. Most of the speakers refused to attach any pathological character to dipsomania, to regard it as a disease at all, but we do not consider that the question is at all affected by this fact. Whether a man is a lunatic or is afflicted with an unconquerable habit which makes him act as a lunatic, the results to himself and the public are about the same, and as it is abundantly proved that the habit cannot be controlled or influenced by punishment or remonstrance any more than lunacy itself can be, it seems to us unnecessary to discuss whether there are pathological lesions or not. Mr. Hepworth Dixon, as the exponent of extra-professional views on the subject, spoke warmly in favour of controlling legislation, and the association finally evinced its interest in the subject, and its belief in the future of the movement by appointing a committee to watch and assist legislation in the matter. We can hardly hope that a year or two will bring forth any useful measure on so serious a subject, but we prophesy that before long we shall be wondering how it was that a miserable, self-condemned madman, should have been so long permitted to subject himself to slow suicide and his family to disgrace and misery.

### The Sanitary condition of Londesborough Lodge.

In another article we had already expressed grave doubts as to the statements put forward by our contemporaries, and we think it right to give publicity to the following statement that appeared in the daily papers on Monday last:—

"Sir,—We, the undersigned, have this day instituted a careful and searching investigation into the drainage of Londesborough Lodge, and beg to say that all the drains inside that part of the house receiving water-closet soil-pipes are glazed sanitary tubes. These tubes are from four to nine inches in diameter, and have a fall of one and a half inches in ten feet.

"We found no deposit or smell in the drains; there is no cesspool of the kind described by the *British Medical Journal* commissioner inside the house or anywhere about the premises. In the basement under the scullery there is a brick effluvium trap, cemented inside and in perfect order. This trap is eighteen inches wide, thirty-six inches in length, and has a depth of fourteen inches of water in it; dip of trapstone into water three inches. No deposit found. This trap was cleaned out before the arrival of Lord Londesborough's family for the autumn, and is capped with a flag laid in cement. The soil-pipe from the water-closet used by the Prince opens directly into the main drain, and, as we have already stated, there is no cesspool

as alleged. The upper end of this soil pipe, after passing through the open cistern on the roof, opens freely to the air, forming a ventilating shaft to the drains, and to the Prince's water-closet in particular. The *Lancet* commissioner was misinformed by the plumber's man on this point. A four-inch iron rain-water-pipe runs into the main drain, outside the house, near to the junction of the soil-pipe from the Prince's closet; it runs directly upwards to the eaves of the roof, where it ends, and serves as a second ventilating shaft to the drainage of Londesborough Lodge. We are of opinion this contrivance would allow any pent-up sewage gases in the main drain to escape above the roof of the house, and not press unduly on the water-closet traps. This contrivance was not pointed out to the sanitary commissioners who have reported upon the condition of Londesborough Lodge, as it undoubtedly should have been.

(Signed) "GEORGE P. DALE, F.R.C.S.

"JOHN WM. TAYLOR, M.D., Medical Officer to the Local Board.

"STEWART and BURY, Architects, Scarborough.

"WILLIAM P. A. COCK, Contractor, Scarborough.

"J. H. CARROLL, Clerk of the Works.

"SEPTIMUS BLAND, Plumber.

"Scarborough, Dec. 9, 1871.

"I was present at, and took part in, the examination of Londesborough Lodge, now made, and certify that the facts above stated are correct.

"J. H. SPALLARD, M.D., one of the Sanitary Commissioners of the *Lancet*."

### The Bengal Medical Service.

THE *Pioneer* says that the officers of the Bengal Medical Service will be shortly called upon to elect either for military service or civil employ. The Madras Medical Department has already ascertained the wishes of its officers in this matter. It is to be hoped, however, that the Bengal officers, before being called on to make a decision, will be furnished with more information than seems to have been given to their brethren of Madras. They should clearly understand whether if, on electing for military service, they will be allowed to serve in European regiments and to exchange with officers of the sister service; whether the medical charge of hill stations will still remain in the gift of the Commander-in-Chief; whether Foreign Department appointments (such as medical charge of political agencies) will be considered as civil or military in their character. The disruption of this service seems inevitable, as it has become out of harmony with the times, having withstood longer than any other of the Company's institutions the storms which have swept away an army and a navy and many another system. We trust that Government will, by wise and liberal treatment, render the death of this fine old service as easy as possible.

WE understand that out of a total strength of 700 men in the 105th regiment now stationed in India, one-seventh are in hospital.

THE next Competitive Examination for appointments as assistant surgeons in the Royal Navy, will be held in London in February next.

WE have pleasure in announcing that an Italian translation of Dr. Tilt's "Change of Life" from the able pen of Dr. Eugenie Rey will shortly appear at Rome.

ASSISTANT-SURGEON FRANCIS H. WELCH, 1st Battalion, 22nd Regiment, has been appointed Assistant-Professor of Pathology at the Army Medical School, vice Staff Assistant-Surgeon Vivian Wearne, who has resigned on account of ill-health.

## SPECIAL CORRESPONDENCE.

(FROM OUR SPECIAL CORRESPONDENT.)

VIENNA, November 24, 1871.

### ON THE ABSORPTION OF BLUE OINTMENT AND OF SUBLIMATE BY THE UNWOUNDED SKIN.

A MICROSCOPICO-CHEMICAL study has appeared by Professor Dr. Neumann, which is very interesting. He says there are five questions to answer to:—

1. Does mercury, rubbed into the unwounded skin, penetrate through it into the organism?
2. What are the ways by which mercury enters the body?
3. Can the *hypothesis* (that mercury enters the body in the form of metal, and that it circulates in that form in the blood) be proved by the microscope?
4. Can the mercury rubbed into the skin be found in the interior organs chemically or microscopically?
5. Is corrosive sublimate dissolved in a bath, received by the unwounded skin?

Dr. Neumann asserts that the known physical properties of the globules of mercury in blue ointment are only appreciated under a certain limit, beyond which limit even the best microscopist can no longer make a difference between globules of mercury and bubbles of air, molecular grease, molecular detritus, microconus, carbonate of lime.

That question can only be resolved by combined method:—

- a. First the entering of the globules must be proved.
- b. Then their presence in the blood and in the organs must be searched for chemically.

The best method for that is Professor Schneider's, who makes an amalgam by small leaves of gold, and by the mercury excreted from the body—then a metallic mirror is created by combination with vapours of iodine; then the iodide of mercury appears by its characteristic colour and crystals.

*Experiments* have been made on dogs, rabbits, frogs, on the skin of new-born children, and on living men, and on those parts of the body which were destined for amputation; then on bladders and pericardium.

In order to prevent on living animals the *licking* off of the rubbed parts, bandages were applied, also the injection with curare was made after long rubbing, or with a solution of chloral, after which experiment the animal lives still some hours (27 hours—4 hours). But the skin should not be excoriated by rubbing. Gold coins were also interpolated in the subcutaneous tissue, and in the cavity of the chest and abdomen to detect the amalgamation.

The *opinion* that the mercury enters into the apparatus of breathing during the rubbing is refuted by the proof that mercury changes into vapour only by high temperature. Other *physiologists* object that very thin molecules of mercury which are suspended in the air may enter in the body by the mouth. Dr. Neumann refutes this opinion by the following experiments. He separates the head and the anterior part of the body by a correspondent aperture in the window, from the atmosphere in which the innunction takes place, so that no particle of mercury could be breathed. Of those experiments the results were the following:—By rubbing the blue ointment in the unwounded skin globules of mercury enter by the air follicles as far as the bulb in the sebaceous glands, which have an open aperture, and then they enter in the superior part of the sudoriferous glands. But Dr. Neumann could not find what direction the globules take from there till the apparatus of circulation, and in what form; probably they are changed into sublimate, and are resolved by the superficial lymphatic system.

On the contrary, the rubbed mercury as blue ointment can in the blood, and in the interior organs only be found by chemical methods, also the sublimate when it is received by the unwounded skin.

Globules of mercury could never be found in the subcutaneous tissue and in the cutis vera.

## Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

NOVEMBER 27TH, 1871.

DR. ANDREW CLARKE, President, in the Chair.

### UNIQUE CASE OF IMPALEMENT.

MR. ALFRED FREER, of Stourbridge, communicated the following case of *impalement*. On the evening of the 9th of August, 1870, I was sent for to see an Irishwoman, æt. thirty-three, the mother of two children, who was said to be dying. It appeared that having finished her work at the top of a corn rick, she chose to slide off instead of getting down by the ladder; some one had left a hay fork with the handle uppermost against the stack. She slid down and lighted on the ground upright, impaled on the fork. The farmer ran to her, and with much difficulty succeeded in pulling the fork out of her body, she assured me that it was bloody fully two feet up the stick, the woman fainted and was sick, some brandy was given to her, she was placed in a carriage and brought home. I found her lying on a brick floor, and having lost much blood she was cold and almost pulseless, but sensible and complaining of great pain in the region of the heart. Breathing very hurried and irregular; a little blood flowing from the vagina. Upon examination, I found this organ uninjured, but on the left side of the unimpregnated uterus about two inches or less from the os cervicis, my index finger passed to its root into a large irregularly cut wound apparently formed at the junction of the uterus with the left ligament. I withdrew my finger, and as there was a great gush of blood, I proceeded to plug, filling the wound bit by bit with strips of lint, and could have pushed in any amount of this evidently into the peritoneal cavity. The hemorrhage ceased, and I proceeded to examine the side, and found the sixth rib broken midway between the spine and the sternum. Considerable emphysematous crackling reaching up the axilla (punctured pleura). I applied a large plaster and a body bandage, and gave an ether mixture, the woman was too ill to be moved, and lay all night on the floor. August 10.—Has rallied from the collapse; vomits frequently; quick respiration; pulse 120; urine clear. Aug. 11.—Very thirsty; constant cough; great pain in left side; the vomiting has ceased. August 12.—Better, but suffering from pleurisy; abdomen free from pain and swelling; "soreness;" complained from the pubic region towards the left axilla; no further vagina bleeding, so tried to day to withdraw the plug, but after pulling away the first strip, some bleeding began, so desisted. Aug. 14.—Withdrew the remaining plug. From this date the woman steadily improved, on the 21st, I found all emphysematous swelling gone, and she had become bright and cheerful. Beyond a dose of castor oil repeated two or three times, and a full dose of calomel and opium on the 12th to allay pain and produce sleep, the medical treatment was nil. September 3.—She was downstairs washing a table as cheerful as possible, but a bit "wake." December 4.—She seems perfectly well; has been poorly at two periods since the accident; says she sometimes feels a pain after hard work, just where the fork struck her. So speedily and complete a recovery after such an impalement is very remarkable. "I felt it go up to my side" said the poor woman, and beyond all doubt, the pike penetrated by the side of the body of the uterus, traversed the abdominal cavity, and

impinging on the diaphragm, pushed with such force against the rib as to break it. I attribute her recovery to one circumstance alone, that the rounded smooth big end of the pike entered her body, and not one of the forks, and that therefore the intestines were pushed before it, and thus escaped injury.

DR. WILTSHIRE then read a paper on "Adhesion of the Lungs after Small-Pox."

MR. CARTER afterwards gave a series of interesting ophthalmoscopic demonstrations.

#### EDEMA OF THE LUNG AFTER SMALL-POX.

DR. WILTSHIRE communicated the following case,

Miss P., had small-pox somewhat severely in July last, and six months afterwards there was a considerable amount of anasarca of the lower extremities. There was also a slight cough. One day the dropsy of the legs suddenly disappeared almost completely, and about twelve hours after severe dyspnoea, violent cough and expectoration of enormous quantities of glairy phlegm came on; the attack was so severe, that the patient's life was in great jeopardy. In addition to all the signs of œdema of the lungs, the heart was feeble, and there was a little, but by no means a marked amount of albumen in the urine, which latter was not scanty. The exhibition of repeated doses of compound jalap powder, ammonia, ether, and digitalis, swathing in hot blankets, and the administration of brandy gave the patient great relief, and under this treatment she rallied and made a good recovery.

#### WEBBED FINGERS.

MR. WILLIAM ADAMS showed a boy who had a webbed hand, which was being healed by Mr. Tamplin's instrument. The deformity is not uncommon, but the great difficulty is to prevent the fingers rejoining after the operation. The case was in the first stage of the treatment; a hole with its circumference cicatrised, had been made at the base of the webbed fingers, a pencil case could be passed through it, simple division gives only a slight improvement; a plastic operation gives a better result. Silver rings to make an opening have been used, but Mr. Tamplin's operation by which a piece of skin is screwed out by means of two plates of metal is the best. The tissues compressed soon slough out, and the hole is well stuffed with oiled lint, the inflammation and general swelling soon pass off. The operation has been done a month, and the edges of the opening are well cicatrised, and the hole permanent. The remainder of the web will be treated in the usual way, by division with the knife.

MR. BRUDENELL CARTER demonstrated the following interesting ophthalmic cases. I. A boy had received a blow on the eye, the lids being closed, with a cricket bat, the ciliary nerves were either ruptured or damaged, there was also irritation of the sympathetic filaments, as the pupil was enormously dilated. The chorioid pigment was started through the tissues around the optic disc; the chorioid tissues are wasted below the optic disc. There was a white line at one spot, some would say it was a rupture of the chorioid, but he did not think so himself. II. A man suffering from double optic retinitis, from the presence of a cerebral tumour. At present there were no cerebral symptoms. The outline of the disc was veiled by effusion and œdema, the veins tortuous and congested, bending in and out. III. A case of albuminoid retinitis. Bright white spots were present in the retina with splashes of hæmorrhage. IV. A boy who had sustained an injury to the head and spinal columns. Hæmorrhage took place into the orbit, and protruded the ball of the eye, there was absolute loss of vision, the optic nerve being atrophied. After exposure to the full light of the instrument, he saw a little at the outer and the inner quadrant of the field. V. A case of syphilitic retinitis nearly well. There was at the centre of the disc a little cloud over the vessels, the sight was but slightly impaired. The fibrous element of the nerve tissue is affected. In a few words the author explained the mode of managing the ophthalmoscope, which required no special skill to use, and pointed out the extreme value the instrument possessed in many interesting cases of general medicine.

#### Milk as an Article of Diet.

A WRITER in the *Journal of Applied Chemistry* states that in order to render milk digestible its particles should be divided, which can be effected by bread or some other farinaceous article. When cooked with rice and eggs (rice pudding) it forms the type of a proper food; containing nitrogens, phosphates, and starch. Milk, when used as a drink, should be boiled, then diluted with water. The solid matter of milk

constitutes a little more than 12½ per cent. of the whole, of which more than one-third is caseine, or the cheese principle, about one quarter is butter, and the balance sugar and salts. Of these substances the butter and sugar supply heat to the body, while the caseine contains tissue-making material in a most concentrated form—*Med. Record.*

## Literature.

### FISTULA, HÆMORRHOIDS, PAINFUL ULCER, STRICTURE, PROLAPSE, AND OTHER DISEASES OF THE RECTUM.\*

THIS is certainly the most complete work on diseases of the rectum, that it has been our lot for some time to criticise, and should be read by all practical men. Mr. Allingham divides his book into seventeen chapters. Some forms of rectal disease are more common than others, notably, fistula and piles. Out of 4,000 cases seen at St. Mark's Hospital, there were 1,208 of fistula, and 965 of external and internal piles. No examination of the rectum can be considered complete, which is not preceded by an injection of warm water. After this, the educated finger gives all the information as to the state of the rectum needed, if any speculum is used, the ordinary plated metal speculum open at one side, and at the side with a wooden plug is the best. The patient should be placed in the prone position, with the hips well elevated on hard pillows, so that the intestines may gravitate towards the diaphragm.

Fistula in ano is the most common disease of the rectum in adults. Infants may suffer from it, and aged people also. Constipation, foreign bodies swallowed, and exposure to wet and cold may cause it. Sitting on damp seats, or scrofula, may be antecedents. It usually commences by an abscess just beneath the skin at the margin of the anus; but may commence by ulceration of the mucous membrane of the rectum in consumptive patients. For the most part, such abscesses form rapidly, and as soon as pus forms, there is but one way of treating, namely, incision, and this operation often prevents the formation of a fistula. Very few fistulas exist for more than three months without the formation of an internal opening in the rectum; but there are occasionally blind external and blind internal fistulae. The latter are usually found in consumptive patients. The internal opening in fistula is usually situated just within the anus, or the depression between the internal and external sphincters; but when the abscess commences on the ischio-rectal fossa, it opens usually far up in the rectum. The sinus sometimes runs right round the bowel. Fistulae may sometimes exist for years without much damage to the patient's health. In most cases they require the use of the knife. Setons may be used in some timid people, or in consumptives; but this is more painful than the knife.

The bowels should be cleared out by a purge, before operating on a case of fistula. A Brodie's probe-director, made of steel, is oiled and passed through the external and internal openings, and the point is turned out of the anus, after which a bistoury divides the bridge of tissues. The sinus above the internal opening, must be then opened, if one exists; and lateral fistulae opened, and with a pair of scissors, the overlapping pieces of skin may be removed. After the operation, some finely-carded cotton wool is placed well into the bottom of the wound, and packed in. If the rectal sinus be so high that the point of the probe cannot be brought out of the anus, the spring scissors and special director of Ferguson, is used by our author. Mr. Lake, in 1845, recommended in such

\* "Fistula, Hæmorrhoids, Painful Ulcer, Stricture, Prolapse, and other Diseases of the Rectum, their Diagnosis and Treatment." By William Allingham, F.R.C.S.E., Surgeon to St. Mark's Hospital, &c. London: Churchill, 1871. Pp. 229.

cases, cutting through the tissues with strong twine and a screw tourniquet. Blind internal fistulæ must be made into complete fistulæ, and cured in the same manner. After the operation, the bowels should be kept confined for three days, when a purge may be given; very little dressing is required, and *nimia diligentia* avoided. Patient should lie still for some time, however.

Most writers have said that fistulæ in phthisical persons should not be interfered with. In a large number of persons with fistulæ, Mr. Allingham has found phthisis to exist, probably as much as fourteen per cent. Mr. Allingham is in favour of operating in picked cases, on fistulæ occurring in persons with tubercles in the lung; because in some cases the patient lives a long life, even after the occurrence of this disease. The wound frequently heals kindly, and the patient's health is often improved by the operation. The sphincter should, if possible, not be divided in such cases; because if this is done, it is very apt to lead to incontinence of feces.

Piles are divided into external and internal, although external piles do encroach on the mucous membrane, and are, therefore, partially internal. External piles are either true hypertrophies of the skin, or rounded venous-looking tumours. Internal piles are tumours originating within the anus, although they may have been forced down outside. External piles are very common. Obstructions of the liver, fecal accumulations, constipation, diarrhœa, smoking, alcohol, pregnancy, and violent and prolonged exertion, with exposure, are among the causes assigned by our author, for the appearance of hæmorrhoids. Some consider that external piles are often coagulations of blood in varicose veins, others that they are extravasations of blood in the connective tissue.

In such cases, Mr. Allingham recommends abstinence from beer, spirits, and tobacco; smoking often causes a sympathetic irritation of the throat and rectum. The etheriser is used by our author, whilst removing the redundant skin, in cases of external piles; or opening the venous tumours and pressing out the clots; or the swollen parts may be smeared over with equal parts of extract of belladonna, and extract of opium. Gail ointment and purgatives should be avoided when such piles are inflamed. The patient should live sparingly, avoid coffee and tobacco and alcohol, and use equal parts of confection of pepper, senna, and sulphur, as a laxative.

Internal piles often come on after parturition; they may be very small, or as large as an ordinary hen's egg. Some remain up, others in long-standing cases are always down. Usually patients do not suffer much from such piles, unless they are often coming down, and getting inflamed. Internal piles are either venous, capillary, or arterial. Much blood may be lost from little capillary piles, which are often seated far up in the bowel. These piles resemble nævi. The arterial internal pile often is of great size, and supplied by large arterial branches. It consists of a number of arteries, and veins anastomosing. The venous internal pile is often very large, and of a livid hue, and this is the form which spirit drinkers get. These last may always be operated on. It is the capillary pile which is benefited by the application of fuming nitric acid. Mr. Allingham prefers the persulphate of iron, one scruple in half an ounce of glycerine, as an application, when operation is refused. Ten years ago, the nitric acid was much praised, and was then used recklessly.

In arterial hæmorrhoids, the parts discharge a gummy acid mucus, which stains the linen, and the disease is always present to the mind of the sufferer from the unpleasant sensations experienced. The piles are constantly liable to come down, and be nipped by the sphincter. When strangulated, a bladder of ice may be placed over the parts for an hour, and then they may be returned or operated on at once. The piles may be smeared over with persulphate of iron, and cold water frequently injected. In venous piles, exercise with careful diet will often effect a cure; and when women suffering from piles have displacement of the womb, such cases do not do

well for operation; but the disease of the womb may be treated.

As to operations on piles, we have to choose between ligature, clamp, and cautery, the *écraseur* and galvanocautery; the last, Mr. Allingham cannot as yet recommend. The *écraseur* is barbarous and unscientific when applied to piles. Mr. H. Smith's plan of clamp and cautery has some merits. It is thus used, the patient having protruded the piles, one of the piles is seized by a vulsellum and drawn down, and the clamp applied; the pile is cut off with a pair of scissors not too close to the clamp, and then the stump cauterised by a hot iron, at a dull red heat. Other piles are treated similarly.

Ligature is by far the best operation when thus performed. The piles are seized one after the other, and drawn down; a sharp pair of strong spring scissors separates the pile from its connection with the muscular and sub-mucous tissues on which it rests; the cut is made in the white mark, where the skin meets the mucous membrane, and carried up the bowel, and parallel to it to such a distance that the pile is left, connected by an isthmus of vessels and mucous membrane only. The vessels enter the upper part of the pile. The ligature of silk, well waxed, is tied deep in the furrow; an opiate injection used, and the bowels confined for some days. Some pain is felt on first action of bowels. The ligatures separate in about a week, and the patient may lie down all that time. Hypodermic injection of morphia is useful to lull the pain after operation. Warm hip-baths, if there is retention of urine. In 1,763 cases of operations on piles, at St. Mark's Hospital, there were five cases of tetanus, four of which occurred in 1858. Fissure is often associated with piles, and may always be suspected when the patient says that pain is suffered on defæcation or long after. An incision should be made through the fissure to set the sphincter at rest. Bleeding after the operation is rare, when Mr. Allingham's plan of ligature is made use of. The bowel must be drawn down and the bleeding vessel tied, or the rectum may be plugged. To do the latter, a full sized bell-shaped sponge should be used, with plenty of cotton-wadding, and persulphate of iron, or powdered alum. The sponge should be carried up the bowel, at least five inches. Cotton wool may then be packed in; the plug should remain a week.

The origin of many fissures of the rectum is syphilitic. The agony in fissure is often acute. In children it is always curable without operation. Unguentum zinci, and extract of belladonna may be used. When the patient strains down, we see just within the orifice, an elongated club-shaped ulcer. Fissures of recent origin may usually be cured without operation, by recommending rest on the sofa, with mild laxatives, equal parts of the confection of senna and confection of sulphur, whilst for local applications, an ointment composed of four grains of calomel, two of extract of belladonna, and two pulv. opii, in a drachm of lard. Occasional touching with nitrate of silver is useful. If the ulcer is grey and hard at its base, the knife may be used. Fuming nitric, or acid nitrate of mercury should be used. In some cases, a very superficial incision is all that is required; but Mr. Allingham is in favour of a rather free incision. A speculum may be introduced, and the incision should commence a little above the upper end of the fissure, and terminate a little beyond its outer end, its depth being not less than a quarter of an inch. In all but the slightest cases, the sphincter must be divided. Forcible dilatation is not a good plan.

Pylpus of the rectum is not so uncommon as has been supposed. Mr. Allingham has met with fifteen in children, and fourteen in adults. They are almost always soft or follicular. As a rule, these growths should be ligatured.

Ulceration of the rectum is not uncommon. The earliest symptom is morning diarrhœa, attended with gripping pain across the lower part of the abdomen; burning pain after stool; pus and blood. Patient becomes dyspeptic, and has pains in back, hips, and down the

legs. An ulcer may, in such cases, be felt seated dorsally about one and a half inches above the anus, and this can be seen by the speculum. The ulceration may be confined to a part of the circumference of the bowel, or may extend all round, and frightful lesions may ensue. It is frequently very difficult to assign any cause for such ulcerations. Ulcers are frequently syphilitic in character, and struma causes ulceration in some cases. In early stages the best treatment of ulceration is a diet composed solely of milk, or curds and whey. Two and a half quarts may be taken in the twenty-four hours. Mr. Allingham has kept patients on this diet for three or four weeks. This effects a cure in many cases. In the most advanced stages of ulceration and stricture, nothing short of lumbar colotomy is available. This operation is often curative, and if the fistula could only be made to close, it would be a most great and real triumph in operative surgery.

Stricture of the rectum, without ulceration, is somewhat uncommon. In some cases, there is much spasm in these strictures. Pressure of the child's head in labour may cause stricture, or constipation. The stools are usually in small pieces. The discharge is like the white of an egg, or jelly-fish, when the bowels first act. Pain is referred to perineum, thighs, &c. In treating this disease, gentle dilatation is the only means advisable. Todd's dilator should never be used. Bougies should be conical, passed gently, and remain in only a minute thrice a week. Barnes's bags may, also, sometimes be useful.

There is tendency to relapse, and when cured, a bougie should be passed once a month. Elastic bougies should be used, and a tape tied to the end. A little oil should be first injected: Prolapse of the rectum is a descent of the lower part of the rectum and sub-mucous tissue, both occasionally thickened, being turned out of the anus. The appearance and touch of prolapse, differs from piles in its not being smooth, hard, and shiny, but soft and velvety. In prociidentia recti, the upper part of the rectum descends through the anus. Sometimes the upper part descends through the lower. When prolapse is caused by piles, these should be cured. When prolapse occurs in children, they should never be allowed to strain at stool; when the bowels have acted, the parts should be sluiced with cold water, and then a solution of alum, applied with a sponge, before they are returned. In bad cases, nitric acid is advised locally, chloroform being given, and the gut well dried first. The acid is to be applied all over it. When the parts are returned, the rectum is to be stuffed with wool, and a pad applied; and the bowels confined three or four days. In the adult, prociidentia is often incurable, strong nitric does temporary good, and our author likes strong carbolic acid daily. The gut may be narrowed by cutting out elliptical pieces, and bringing the edges together with carbolised catgut. An india-rubber pad as an anal support, with a T bandage, is sometimes all that can be used. The powder of baked acorns is recommended in such cases, and when diarrhoea exists, one drachm for a dose.

Puritus ani is a distressing complaint. It requires careful diet to cure it. The irritation is usually worse at night. Liver affections, internal piles, constipation, and parasites may cause it. Sometimes there is seen an eczematous rash; at others, there is a dry wrinkled condition. Excesses at table, or smoking, excite the disorder. Beer and spirits should be left off. Exercise should be taken, and slight purges, with an ointment consisting of ten grains of calomel, in a drachm of ungt. sambuci. A lotion composed of borax, two drachms, sixteen grains of hydroch. of morphia, with half an ounce of dilute hydrocyanic acid, two ounces of glycerine, in an eight ounce lotion may be used. Chloroform pomade, of two drachms of chloroform, in half an ounce of glycerine, and an ounce and a half of ungt. sam., is recommended.

Impaction of feces takes place occasionally in the pouch of the rectum, immediately above the internal sphincter muscle; is caused by a loss of muscular power

in the rectum. A tumour is seen on the region of the sigmoid flexure, and may be taken for cancer. Patient has often diarrhoea without relief. The anus is seen to be nipple shaped, and the finger on being introduced into the bowel, distinguishes a mass of impacted feces. This must be removed with a scoop, and then great care in diet observed. When substances pass into the alimentary canal, we should make the patient eat freely of solid food, such as bread, suet-dumpling, &c.

Cancer of the rectum is the most painful of all diseases; is commonly met with in middle age. It seems not to have any particular cause. It is found as a circumscribed deposit in the sub-mucous tissue, forming a tumour, generally about three inches from the anus. There is a sloughy dark coloured ulcer seen, with a great fetor. The rectal glands become involved, and secondary deposits take place. Patients may succumb in a few months. Colotomy may prolong life for years. Excision is only to be thought of in epithelioma.

Rodent ulcer is nearly allied to cancer. It has no indurated margin, as rodent ulcer of the face has. It is as deadly as cancer; but not so rapid in its course. The shape of the ulcer is irregular, its edges sharply cut and not hard; its surface red and dry. It usually spreads superficially. It seems to exist in scrofulous persons, and causes terrible agony, which kills the patient in many cases.

In chapter seventeen, our author treats of neuralgia of the rectum, and of inflammation of the rectum, in which latter the symptoms are heat, tenesmus, and perhaps discharge of blood and mucus. Injections of starch and opium are recommended. The author has rarely seen primary syphilitic disease of the rectum. Gonorrhoea of the rectum he has seen in three cases in prostitutes. There was great heat and burning pain with a copious discharge of pus; the mucous membrane was intensely inflamed. Lead lotion cured them easily.

If we have conveyed to the reader any idea of the contents of Mr. Allingham's admirable work, we are sure that he will agree with us that none which has issued from the press on this special subject, can at all approach it in precision, clearness, and practical good sense. We predict for it an immense success, and for the author a very high place among the surgeons of London, as a reward for his labour.

## Correspondence.

### THE DISCOVERY OF THE CIRCULATION OF THE BLOOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Even previous to my perusal of the very interesting letters of Dr. McKeogh and Mr. Biddle, published respectively in the last and previous issues of your journal, I was not under the impression that Harvey first originated the idea that the blood was in a continual movement, or as Dr. McKeogh more aptly expresses it, was "the real discoverer of the circulation." I remember as a student in the University of Dublin being thoroughly imbued with the idea that, although Harvey by bringing the observations of his predecessors to culminate in this direction, and adding many of his own, first showed that the blood circulated through the whole system and explained the *modus operandi* of the world; yet the fact of the blood being in a state of motion was well known to many before his time; as for instance, to Fabricius d'Aquapendente who, if my memory serves me, first observed the presence of valves in the veins. There is a great difference in being aware of the blood constantly moving and of there being a great circulatory system; that the ancients were aware of the former is certain as Dr. McKeogh has shown in his translation of a quotation from Plato used by Longinus, and as also Mr. Biddle endeavours to demonstrate by reference to that beautiful yet obscure passage in Ecclesiastes and its construction in the Septuagint version to which he alludes. Cicero again may be

found expressing himself "sanguis per venas in omne corpus difunditur et spiritus per arterias." But although that same author again expresses himself with regard to pulsation "venæ et arteriæ micare non desinunt." I cannot agree with Dr. McKeogh that a philosopher of antiquity could have used any one word as synonymous for either a vein or an artery, as the arteries from the empty condition in which they were found after death and supposed by Erasistratus (who flourished B.C. 300 to 260) to contain air, were so named (*αἰρῆσις*, *arteria*, or *arterium* as it has been written, properly signifying a wind-pipe), and Cicero in the first quotation I have used appears to labour under the same impression. Certainly if Erasistratus was the first to promulgate the opinion it is possible that Plato, who lived before him, may have believed them like the veins to contain blood, but such is highly improbable, as it remained for Galen subsequently to demonstrate that very fact. And as it was when at Rome that that great anatomist and physician is believed to have written his celebrated treatises it could not have been until after A.D., 170, at which date he attended the Emperor Aurelius at Rome. In a little work I read some months ago wherein this philosophical discovery of Galen's was just cursorily alluded to there was a brief statement also to the effect that Servetus Columbo and Cesalpinus ascertained that the blood passed from the right side of the heart and returned through the lungs by the left side. Should this be the case, as I have no cause to doubt, there was a great way made towards the explanation of the real "wheel at the cistern" as at present understood.

Whilst thanking Messrs. McKeogh and Biddle for their truly interesting allusion to medico-literary history, and coinciding with both in the opinion that not only had moderns who lived before the days of Harvey, "but even the ancients, a belief in the "continual movement of the blood," we may still regard the illustrious Harvey as the discoverer of the circulation and one of those whose noble names never fail, in that celebrity of which we are so justly proud, to heap honour and dignity upon their fellow countrymen.

I am, Sir, your obedient Servant,

FRANCIS E. CLARKE, B.A., M.B.

Oughterard, Galway,  
Dec. 8th, 1871.

## Foreign Medical Literature.

### DR. ULLERSBERGER ON ELECTRICITY

IN

#### DISEASES OF CHILDREN.

(Continued from Page )

In the first place, we shall ask, which are the diseases that can be treated by electrization?

- |  |  |
|--|--|
| 1. Hyperæsthesiæ.                        | } Neuralgia and the various neuralgic diseases.<br>a. Cutaneous.<br>b. Muscular.<br>c. Their mutual complications.   |
| 2. Anæsthesiæ.                           |  |
| 3. Spasms.                               |  |
|  | } a. Peripheral.<br>b. Central.<br>c. Vertigos, oscillations, convulsive movements, tremblings, contractions, spasms, characterised by tonic or clonic contractions. |
| 4. Paralysis                             |  |
| 5. Diseases of secretion or excretion.   |  |
| 6. Tumours, swellings, and tumefactions. |  |

Electro-therapeutics offer anodyne, antispastic, antiparalytic, and catalytic effects in the diseases of children, and the general physiological effects are evidenced:

(a.) By the increased determination of the blood, accompanied by elevation of the temperature and increased size of the parts stimulated by electrization.

(b.) By an increased energetic contraction of the blood-vessels.

(c.) In overcoming and preventing all subsequent alterations arising from innervation and inaction of the muscles.

(d.) In restoring sensation which has been suspended or entirely destroyed; in restoring the nervous energy, consequently in stimulating innervation.

(e.) In fine, electricity is able to develop even a supplementary activity.

The electric current is applicable as an exciter of muscular force in a state of paralysis as well as of paralysed sensibility, that is to say, anæsthesia.

In overcoming neuralgia, spasms, paralysis, and anæsthesia by means of electricity, the complication of causes is concerned in the indication for the different electric methods.

Enfeebled energy of the nervous system, nervous torpor, pathological irritability, excess of sensibility, inequality in the transformation of organic substances and of the process of nutrition, are most frequently met with in new-born babes, nursing infants, and young children.

In childhood, also, electricity is the best means of exciting the motor nerves and the muscles. There are notably few medicines capable of increasing the activity of the nerves, while galvanism and electricity are infallible.

On the other hand, this remedy in no way excludes the simultaneous use of other remedies. On the contrary, the proper adjuvants may aid and powerfully assist the therapeutical object.

In treating a sick child by means of electricity, the following must be observed:

(a.) We must find the cause of the pathological disturbance; this is indispensable, in order to determine the rational indication.

(b.) It is absolutely necessary to ascertain whether there is a possibility of curing or ameliorating the disease by means of electro-medication.

(c.) To decide upon the mode of electrization so that the electro-therapeutical method is suitable to the symptoms.

The diseases amenable to treatment by electro-therapeutics are:

1. Neuralgia.
2. Anæsthesia.
3. Spasms, with different degree of convulsive movements.
4. Paralysis.
5. Certain irregularities of secretion and excretion.
6. Phrenopathics.

In specialising the large class of *nervous diseases treatable by electric medication*, experience and clinical observation present us with the following nervous and muscular diseases:

1. Diseases of the senses, impairment of vision, scotoma, myodesopsia, amblyopia, amaurosis, dulness of hearing, and the different degrees of or complete deafness, aphonia and aphasia. The pathological conditions of these affections vary from simple functional weakness to complete paralysis.
2. Spasms and convulsions.
3. Paralysis, with its modifications of degrees.
4. Anæsthesia.

Pathological numbness and weakness have a certain affinity to the different grades of paralysis, and under local paralysis we cannot exclusively comprise hemiplegia, paralysis of motion, partial muscular paralysis, and paralysis of either extremity. Duchenne applied *mediate* electrization in such affections to the muscles, that is, to their nervous trunks, and an *immediate* stimulation of special muscles and their fasciæ—direct muscular Faradisation. Both have their electro-therapeutical applications, that is to say, extra-muscular and intra-muscular stimulating influence over the aforesaid diseases. We include, in these local paralyses, weak vision, amanrotic affections of various degrees, the loss of smell and taste, the different degrees of deafness, aphonia, and rancedorocis, whether congenital or idiopathic.

## Medical News.

**H.R.H. the Prince of Wales.**—The following is the latest bulletin as we are going to press:—"Sandringham, Tuesday morning: His Royal Highness has passed a very restless night. The general state continues unchanged."

**Quacks Pester the Queen.**—We understand that the telegraph wire from Lynn to Sandringham is closed against the public. One reason for this appears to be that persons have pestered the Queen by using the wire in forwarding infallible recipes, or offering their own services.

**Death of Sir James Murray, Bart., M.D.**—The death is announced of this veteran of our profession at the ripe old age of eighty-three. He has been for many years Inspector of Anatomy for Ireland, and physician to the Lord-Lieutenant. He was born in 1788, was educated at Edinburgh and at Trinity College, Dublin, and received the honour of knighthood in 1863. Sir James has contributed several valuable papers to this Journal, all of a scientific nature, for the practical value of which his name was a guarantee.

**Death in an Asylum.**—An inquiry was held at Hanwell Lunatic Asylum last week into the death of a patient named Latuge, who died from violence whilst in the refractory ward. After death the surgeon found a scar on the left knee, one higher up, a bruise on the chest, and a large one on the chin. There was a comminuted fracture of the jaw, a fracture of the tenth and eleventh ribs, an old fracture of the fifth rib, and the right kidney was torn across. The cause of death was laceration of the kidney and hæmorrhage, caused by violence of some kind or other. The jury returned a verdict "That the deceased died from the effects of the injuries he received, but how those injuries were caused there is no evidence to show."

**Metropolitan Asylums Board.**—The Prince of Wales.—At the fortnightly meeting of the Metropolitan Asylums Board on Saturday, at Spring gardens, Dr. Brewer, M.P., in the chair; after the ordinary business, Mr. Furness, of St. Pancras, amidst the most profound silence, said he had the permission of the chairman to ask the managers to give expression to their feeling upon the subject, which he believed was that day occupying the mind of almost every true Englishman. He alluded to the illness of the Prince of Wales (hear, hear). The duties of that board brought them into contact with the humbler classes of society in their sore afflictions of sickness and disease; and, as an important representative body, he felt sure they could not be considered as stepping out of their way to express the deep sorrow they felt with the Queen and Royal family in their present deep and alarming trouble (hear, hear). He moved, "That the managers beg to express their deep sorrow at the dangerous illness of his Royal Highness the Prince of Wales, and record their earnest hope that by the interposition of Divine Providence his recovery will be vouchsafed to the nation" (hear, hear). Mr. W. H. Wyatt, J.P., seconded the resolution. He believed there was scarcely any class of society in this kingdom that did not feel depressed at the deep affliction which had befallen the Royal family in this sad and serious illness of the Prince of Wales, and more especially the amiable consort of his Royal Highness, the Princess of Wales (hear, hear). The motion was at once put, and unanimously carried.

At the present time, when the origin and treatment of fevers are matters of painful interest, it may be well to call attention to a passage in a book written by one Andrew Borde, who, according to Haller, was born at Pevensy, in Sussex, in the early part of the sixteenth century, took the degree of doctor in medicine at Montpellier in 1542, was afterwards a Fellow of the Royal College of Physicians, and one of the physicians of Henry VIII., practising at Winchester. The book is entitled, "The Breviary of Health for all manner of Sycknesses and Diseases, the which may be in man or woman, doth followe, expressyng the obscure termes of Greke, Araby, Latin, and Barbary in English, concerning Physicke and Chirurgerie. Compyled by Andrew Borde, of Physicke Douctour, an Englishman." In this book are accounts of various fevers to which the human body is liable, but chapter 151 is as follows:—"The 151 chapitre doth shew of euyl fever, the which doth comber younge persons, named the fever burden. . . . Among all the fevers I had almoste forgotten the fever burden, with the whiche manye younge men, younge women, maidens, and other younge persons bec sore infected nowe a dayes. 'The cause of this infirmitie:'

This fever doth come naturally, or else by euyl and slouthful bringing up. If it do come by nature, then this fever is uncurable, for it can never out of the flesh that is bred in the bone; if it come by slouthful brynging up it may be helpen by diligent labour. 'A remedy: There is nothing so good for the fever burden as is *unguentum baculinum*—that is to say, take a sticke or wan of a yard of length and more, and let be as great as a man's finger, and with it auoynt the back and the shoulders well morning and evening, and do this twenty-one days; and if this fever wyl not be helpen in that tyme, let them beware of waggynge in the galowes, and whyles they do take theyr medicine, put no lubberwore into theyr potage and feare of knaveryng about theyr here, and if this wyl not helpe, send them to Nevegate, for yf you wyl not, they wyl bringe themselfe thither at length." As some persons may be ignorant of the meaning of the word burden, it should be explained that it means lazy, and is derived by Heylin from the French word *lourd*. It has, however, been used as a synonym for blockhead and sot; and in a book called *Thesus; or, The Flowre of the Commandments*, printed by Wynkyn de Worde in 1521, burdens are classed with evildoers, such as chyldren unnatural, inobedyentes, murderers, theyvs, and false wytnesses.—*The Observer*.

## Insertions.

### MAUGHAM'S SOLUTION OF IRON.

SOME of our preparations of iron are nauseous, and to others there are equal objections. Mr. Maugham has produced a solution which, in numerous cases, will be found agreeable as well as effectual. It appears to be an acid per-acetate. We have already prescribed it in a case in which the sesquichloride was disliked, and shall make further trials of it.

### NOTICES TO CORRESPONDENTS.

DR. LOCKE JOHNSON'S "Notes on Phthisis" will be continued in our next.

G. P.—We congratulate you, and shall be glad to hear further. MR. M. D., Liverpool.—Pamphlet, letters, &c., received. We shall probably revert to the subject in our next.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

To the Editor of "The Medical Press and Circular."

SIR,—Permit me to offer a suggestion to the governing body of the College. "That all members of ten years standing should be elected fellow; or the fellowship offered to those who would accept it in this class."

Yours truly,  
M.D.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED. Transactions of the St. Andrew's Medical Graduates' Association. A Pamphlet by Miss Eye, "On Emigration." Emphysema of the Lungs. By J. B. Berkart, M.D. London: J and A. Churchill.

On the Treatment of Fractures of the Limbs. By Sampson Gamgee, F.R.S.E. London.

#### APPOINTMENTS.

MATTHEWSON, W., M.D., Consulting Physician to the York Asylum.  
 MORGAN, L. W., M.D., Medical Officer and Public Vaccinator for the  
 Penryn and Rhigos District of the Merthyr Tydfil Union.  
 MULLIGAN, J. W., M.D., Surgeon to the Abert-yehau Iron Works.  
 RUCKLEY, Henry R., L.R.C.S.I., &c., Medical Officer to the Walton  
 District, Woodbridge Union, Royal Oak, and Walton Clubs,  
 Ipswich.  
 THORNTON, J. C., M.D., M.R.C.P.L., M.R.C.S.E., Lecturer on  
 Materia Medica at the Middlesex Hospital Medical College.  
 WACHER, F., M.R.C.S., House-Surgeon to the Canterbury Hospital.

#### Marriages.

BUCHANAN—KENWAY.—On the 23rd ult., at St. Saviour's, Paddington,  
 Walter Buchanan, M.R.C.S.E., to Jessie Withnursht-Kenway,  
 daughter of the late John Seymour Kenway, Esq.  
 LEE—BLIZARD.—On the 4th inst., at the Parish Church, Kilkooly, Wm.  
 E. Lee, M.R.C.S.E., of Fulham, to Fannie Jane, eldest daughter  
 of Mr. George Blizard, of Kilkooly, Tipperary.

#### Deaths.

COLLINGS.—On the 1st inst., at Grange-hill, Guernsey, Adolphus  
 Collings, M.D., formerly Surgeon 40th Regiment, aged 56.  
 JACKSON.—On the 30th ult., M. Jackson, M.R.C.S.E., of Market-  
 Weighton, York-shire, aged 67.  
 MACLEAN.—On the 11th of September, at Timaru, New Zealand, Dr.  
 Duncan MacLean, formerly of Springburn, near Glasgow.  
 MILES.—On the 1st inst., E. M. Miles, L.R.C.P., of Heavitree, aged 71.  
 SCARD.—On the 2nd of Oct., at Balman, near Sydney, New South Wales,  
 Thomas Scard, M.R.C.S.E., aged 35.  
 SEPPEER.—On the 7th inst., at Brompton, J. F. Seppeer, M.R.C.S., aged  
 90.

SHERRY.—Considerable interest at the present time attaches to a large importation of Spanish Sherris, consisting of light delicate wines of Amontillado and Manzanilla character, so much appreciated in Spain, the taste for which is largely increasing in this country. This purchase, which amounts to a hundred thousand gallons, has been made by the firm of W & A Gilbey, and on a recent visit to their stores (which may fairly rank as one of the sights of London) we gleaned some statistics which are of interest at this season of the year. It appears that during last December they sent out no less than 1,164,252 bottles of Wines and Spirits. Permissive Bill agitators will, no doubt, be disposed to use these figures for their own purposes, but it should be borne in mind that this apparently large quantity was distributed throughout the United Kingdom, from Land'send to the Orkney Isles. We find from a recent treatise, that the consumption per head per annum in England is 4 pints of Wine, 8 pints of Spirits, and 170 pints of Beer, a not unreasonable quantity, and we are disposed to think that were our licensing reformers to follow the plan advised by some of the leading medical journals, viz., to discourage public drinking and increase facilities for obtaining what is required for home consumption, much of the present intemperance would disappear from the lower, as it has already done from the middle and upper classes, under the moral effect of home influence and example.—*Morning Post*, Dec. 5

Established 1848.

### PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.

50 LINCOLN'S INN FIELDS, W.C.

J. BAXTER LANGLEY LL.D. M.R.C.S., F.L.S., &c., (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

PRACTICES AND PARTNERSHIPS NOW OPEN for negotiation (in addition to those advertised in Dr. Langley's List, (which is sent post free on application).

Y 360. About sixty miles from LONDON, an old-established PRACTICE; average receipts upwards of £500 a year; appointments £200; no important opposition. The house is a large family residence, containing eleven rooms, with convenient offices, large garden, stabling, &c. The whole is fitted with gas, &c. The patients are chiefly of a very good class, and there are scarcely any bad debts. A younger and more active man could make at least £700 a year. The whole connexion is believed to be transferable.

Y 361. Excellent opportunity of commencing PRACTICE in a flourishing town (Midland). Present income upwards of £200 a year, with scope for unlimited increase. The patients belong to a good class, and an efficient introduction can be given. Premium £30, or the one half of first years receipts secured by deposit.

Y 358. MIDLAND COUNTIES. Safe investment within ten miles of a large town. An old-established practice realising on an average about £500 a year; population 2,700; no opponent within five miles. Patients consist of farmers and middle class, who pay punctually. The Union appointment can be claimed, as there is no doubly qualified resident in the district. The house contains thirteen rooms, with coach-house, stabling, good garden, and paddock, at a normal rent; satisfactory reasons for leaving can be assigned, and the books are open to the fullest investigation.

Y 357. In a pleasant COUNTRY TOWN where there is the best society, and a population of about 10,000. An old-established and respectable practice realising £800 a year; patients good class; longest journeys about four miles. The house is old-fashioned, but convenient, containing fourteen rooms, with stabling and offices, part of the premium may be paid by instalments, but no gentleman need apply who cannot command £500.

Y 354. A first-class PARTNERSHIP in a large provincial town. The present rate of income is about £2,000 a year. Average of several years past is upwards of £1,600. A third or fourth share is offered at two years' purchase, the incomer must have been accustomed to the best society, as the connexion includes the aristocracy of the district.

Y 352. DEVONSHIRE. A pleasant and easily worked PRACTICE, the receipts from which are £300 a year, but which are capable of immense increase by a young active gentleman. Population about 3,000; only one opponent. The house is well situated and convenient, with garden, field, &c., at a low rent. Appointments bring in £75 a year.

Y 345. Within 100 miles of LONDON, in a pleasant agricultural district. Receipts upwards of £500; appointments £125; opposition quite unimportant. House contains thirteen rooms, with coach-house, stabling, garden, and land, within about a mile of the sea; rent £5. The annual value of the appointments would be deducted from the premium, if not secured.

Y 342. In a LARGE CITY. Income £2,000 a year; patients good middle class; residence in a central situation containing sixteen rooms at a moderate rent. Appointments yield £300 a year. Six months active instruction could be given. Books open to the strictest scrutiny. Premium £2,500.

## CLINICAL LECTURES

ON

## DISEASES OF THE EYE,

DELIVERED AT THE ADELAIDE HOSPITAL.

By H. R. SWANZY, M.B., L.R.C.S.I.,

Ophthalmic Surgeon to the Hospital, and Surgeon to the National Eye and Ear Infirmary; late Assistant to the late Professor Von Graefe, Berlin.

### LECTURE IV.—Albuminuric Retinitis.

GENTLEMEN,—This man (J. L., æt. twenty-five, compositor), presented himself at the National Eye and Ear Infirmary a few days ago, complaining of dimness of vision of both eyes. The sight of the right eye was but 2-5ths, and that of the left eye but 1-10th of the normal degree. He said he first perceived his sight to fail ten days or a fortnight previously, while he was reading, and it had been getting worse ever since. He complained only of his eyes, and was obliged to leave off work on this account alone. I examined with the ophthalmoscope, and found those appearances in the retina of each eye which are now known to be characteristic of Bright's disease, and are consequently termed Retinitis Brightii, or Retinitis Albuminurica. (Liebreich's "Atlas of Ophthalmoscopy," pl. xi., figs. 1 and 2.) The diagnosis was placed beyond doubt by an examination of the urine, which we found loaded with albumen. Sp. gr. 1.010. The urine was very pale, and upon inquiry the patient informed us that he had lately passed it in large quantities and frequently. A very careful prognosis was given, and he was advised to place himself under medical treatment in this hospital. He has done so under Dr. Head's care.

It had long been well known that the sight was liable to become affected in Bright's disease, but, until a few years ago, this was believed to depend in every case upon uræmic poisoning. The ophthalmoscope, however, demonstrated that, in a majority of cases, material changes in the retina itself were the cause of the failure of vision.

Although the term *retinitis* is applied to these changes, they are less an inflammation than a degeneration of the retina. You will find in this patient's left eye some swelling of the optic disc (neuritis), and cloudiness of its immediate neighbourhood, the result of serous infiltration and of increase of the normal cellular tissue contained in the retina. The white plaques of different sizes, which you will observe somewhat removed from the papilla, are due partly to fatty degeneration of the cellular tissue, and partly to sclerosis of the nerve fibres. Around the macula lutea there is a very characteristic arrangement of small white spots which appear as rays diverging from the macula in their centre. The appearance depends upon the peculiar arrangement of the cellular tissue at this place, in which fatty degeneration has come on. In the right eye the appearances are very similar, except that the optic disc is less affected. Small retinal echymoses are almost constantly found in Retinitis Brightii, but in this instance they are nearly quite absent. In the left eye I have been able, with difficulty, to discover one or two very minute ones.

Although the older writers were wrong in referring all cases of defective sight in Bright's disease to uræmia as their cause, still, it does sometimes occur. We there find no changes in the retina. The form of blindness is generally temporary only, lasting a few hours or a few days at most, attended with other uræmic symptoms, and passing off with them. In Retinitis Brightii the blindness is generally permanent and need not be attended with any uræmic symptoms.

You might imagine, from the patient's description of the way in which his sight became attacked, that the retinal affection was a very acute one, and that the renal disease upon which it depends was also very acute; but I believe this not to be so. I think it is likely that, if we had had an opportunity of examining his retina three weeks or a month ago we would have found them diseased, and, if the disease has but lately produced functional disturbance, it is probably because, until then, it was limited to the non-nervous structure of the retina. As regards the kidneys, I believe them to be very chronically diseased, although there is nothing in the

patient's appearance, which would suggest to us, as strangers, the diagnosis of Morbus Brightii, still, when we are once on the track, on looking at his face we find its complexion sallow, and a slight puffiness of the under lids, and he tells us that his friends have remarked these changes for some time. Moreover, although he considers himself perfectly healthy, and has been attending steadily to his trade until a week ago, yet he admits that, for the last eight or nine months he has suffered a great deal from indigestion, and not unfrequently has vomited his meals soon after having taken them. Experience also teaches us that it is a chronic form of kidney disease, upon which Ret. Brightii most commonly attends. It seems to be usually the large granular kidney, but often, also, the amyloid, and other chronic forms of Bright's disease. In this case, Dr. Head inclines to the opinion that it is an amyloid kidney. We have been unable to find any tube casts in the urine.

It is remarkable that the eye should have here been the first organ, which, by its functional disturbance in a primary disease of the kidney of so serious a nature, caused the patient to seek for medical advice. And yet this is not a very uncommon circumstance. Everyone who has busied themselves specially with disease of the eye, must have frequently had occasion to diagnose Bright's disease by the ophthalmoscopic appearances, while, as yet, there were no other prominent symptoms. I think, gentlemen, you would be well repaid for the trouble you may have in acquiring a knowledge of the ophthalmoscope, if in after life you should have an opportunity of diagnosing one such case. The use of the ophthalmoscope has been hitherto regarded rather as an accomplishment than as a necessary part of every medical man's education; but, I am happy to say, this view is daily losing ground. I am sure it is to the physicians we have, in future, to look for the most valuable observations yet to be made with this instrument, and those of you who profit by the opportunities you now have, will anything but regret it in five years to come.

The prognosis in this case is of the very worst. As a general rule, in those cases where the eye gives the first indication of the presence of Bright's disease, the progress of the latter is from that time very rapid. From three to six or eight weeks is commonly long enough to bring the case to a fatal termination, and it is rare for these patients to live for three or four months, after the sight has become affected.

It is not easy to comprehend why the retina, of all parts of the nervous system, should be liable to be attacked in this peculiar manner in albuminuria. So far, there has been but one case observed where similar changes were found coexistent in the encephalon. It was a case of Galezowski's\*, where he found, by aid of the microscope, material changes in the chiasma and optic tracts, and in one of the corpora-quadrigenia. These observations have not as yet been corroborated. Some writers of eminence have referred the retinal affection directly to hypertrophy of the heart, which is so common with the granular kidney of Bright's disease, but our case would, in itself, be sufficient to disprove this theory, for the heart is normal†. The treatment is, of course, that suited to the renal disease. Heurteloup's artificial leech applied to the temple is sometimes of benefit. The retinal changes have occasionally been seen to disappear and restoration of good sight to take place; but this is, indeed, very rare‡.

\* Vide Dr. Clifford Allbutt's work on "The Ophthalmoscope in Diseases of the Nervous System and of the Kidneys." P. 237. London: Macmillan and Co. 1871.

† Dr. Allbutt says: "It is scarcely necessary to add that retinitis has never been seen to accompany hypertrophied heart in cases other than renal. It would seem, then, that hypertrophy and the retinitis are concomitant effects of some other causes, and are not themselves, as Traube supposes, related directly." P. 234.

‡ After remaining in the hospital for some time, the patient was brought home by his friends, and died just six weeks after his sight was first attacked.

## Original Communications.

### ON THE TREATMENT OF ECZEMA.

By J. L. MILTON,

Surgeon to St. John's Hospital for Skin Diseases.

(Continued.)

THERE is one form of eczema which is peculiarly refractory,—viz., eczema siccum of the hands. It is seated on the palms of the hands, tips of the fingers, and often over their joints. The skin often looks as if pieces had been chipped or torn out. Sometimes a small patch on the palm of the hand discharges for a time, or this action may be taken on by one or more cracks, especially in workmen where the palm is a good deal fretted by the continual pressure of the tools they use; more frequently the part affected is only red, tender, stiff, and covered only with unhealthy cuticle. It is often seen in those who have to handle a good deal of cloth, and is widely different from the grocer's itch which attacks the backs of the knuckles, hands, and wrists, often discharges serum, which is occasionally complicated with impetigo and is easily cured. The treatment of eczema siccum which has succeeded best in my hands is to give a course of steel and arsenic for some time; to steep the part by means of wet lint wrapped round it, and over this a sponge bag with a cloth tied over the mouth of the bag, and to rub in the ointment of the red iodide of mercury of the "British Pharmacopœia" with at least eight or ten grains of veratria to the ounce, raising the quantity of the iodide, if the patient can bear it, till a drachm to an ounce is reached. These are the only remedies I have ever seen effectual. Mr. Gay has, I believe, used the decoction of hellebore for this affection with great success. He directs it to be well rubbed in and uses no particular internal treatment.\* Dr. Cheadle saw sarsaparilla very useful in a case of this kind (psoriasis palmaris he calls it) where arsenic, cod-liver oil and mercury had all failed.

This is the only form of eczema in which water-dressings, especially when covered with oiled silk or other waterproof materials, are not decidedly injurious. Indeed, the skilful use of these applications will not unfrequently develop an eczema where there was none, as for instance, round an ulcer or a boil.

Eczema siccum, when it fastens on the tips of the fingers and palm of the hand, is often a very serious affair for those who have to gain their living by manual labour. I have had many patients under my care whose earnings had been materially diminished from this cause. One patient, a seamstress, forty-four years old, had, in the course of ten years, unbroken suffering from this affection, been at last brought to such a state that she was incapacitated from following her employment. This woman had been at five hospitals and under different private practitioners. I have reason to think she gave their treatment a fair trial, as she was so extremely regular in her attendance at St. John's. I was not at that time acquainted with the value of the acid solution of iron and the biniodide of mercury ointment, but two or three other forms of mercury in ointment failed, as did the biniodide internally, arsenic, &c. The caustic potass solution, as recommended by Hebra, was tried, but no good resulted from it. The acid nitrate of mercury seemed to do some good, but after the second application I lost sight of the patient. The biniodide of mercury in pills sometimes acts very well in eczema of the lips, especially if free use be, at the same time, made of the compound senna mixture so as to keep the bowels rather loose.

Patients suffering from eczema should never wash in

\* Mr. Gay's prescription is:—

℞ Hellebori rad., ʒij.;  
Aque brilliant, ℥j.;  
Coque ad ʒviij. et adde;  
Eau de Cologne, ʒij., m ft. lotio.

cold water; on the contrary, I think they cannot use it too hot. If expense be no object, a sixteenth to an eighth part of glycerine should be added to the water.\* When the surface is too tender to bear even this I would recommend a decoction of linseed. The uncrushed seed only should be used; four or five tablespoonfuls are put into a quart of water and boiled down to a pint. The fluid is then strained and used hot. Thin gruel, boiled for quite twenty minutes, is also useful; it soothes the irritation of the skin when nothing else is tolerated.

Soaps, should, I think, with one exception be abolished. As a rule, the best kinds are imperfect and contain free alkali. When the soap is dissolved in the water still more alkali is set free, and this acts on the acid fats in the cutaneous secretions. Bad common soaps and the trash generally sold as toilet soaps are still worse; they are made of the coarsest kinds of fat and contain a larger proportion of alkali. In proof of this it may be stated that they are sold much cheaper, even scented, than pure soaps without the addition of such an expensive ingredient can be procured direct from the soap boiler. Most of the foreign soaps are still worse than the English, as in consequence of their being made by what is called the cold process, much more alkali is required to fix the oil. The soaps sold as glycerine, sunflower oil soap, &c., are, in most cases, simply impositions. Price's solidified glycerine contains a large amount of pure glycerine; a very excellent glycerine soap is also made by Messrs. Bell, and no doubt a pure article of this kind can generally be procured from any large chemist; but I have been assured on undoubted authority, that whole tons of soap are got up, bearing, according to the demand in the market, the name of glycerine soap, or sunflower oil soap, and coloured according to the taste of the day, which do not contain a single drop of the liquids from which they take their names. Most of the medicated soaps, if strong enough to have any effect at all, set up such irritation in some persons that they cannot be borne. I have heard several patients complain most bitterly of the suffering they endured from the use of juniper-tar soap.

The one exception I have mentioned is, the transparent soap made by Messrs. Pears originally for St. John's Hospital, and since that time for at least two other hospitals. It is, after boiling, thoroughly dissolved in alcohol, precipitated and made up again. It consists of pure oil and the lowest amount of alkali. It contains no scent and no medical ingredient whatever, and thus produces, perhaps, less irritation in the skin than any known substance of the kind.

It is almost time the authorities agreed on some of these points. Mr. Startin denounces soap† substituting paste made of oatmeal, or gruel made of bran, oatmeal, linseed meal, arrowroot, or starch; or he prescribes warm milk and water, a yolk of egg and water. Mr. Wilson, on the other hand, is such an advocate for soap, that he thinks there can hardly be too much of it; when it sets up too much irritation the fault lies not with the soap but with the skin; if the skin will not bear soap it must be trained to do so. He recommends‡ almost indiscriminately, the better kinds of glycerine soap, Carrick's elder-flower soap and Greux's turtle-oil soap. The latter, I believe, is no longer made, not having proved remunerative. Glycerine soap is, I believe, useful in so far as it does no harm, but I have invariably found yellow soap irritate the skin in eczema however useful it may be in health.

The preparations of tar, such as those of juniper tar, the Russian birch tar, creosote, &c., form so important a group as to merit a notice by themselves. I have had little experience of juniper-tar in eczema, but both the others appeared to me inert. I never saw creosote do any good, and I know that others have noticed the same thing.

Perhaps Mr. Naylor's statement\* that there is a wide difference between the ordinary creosote prepared from wood, and the German creosote obtained from coal tar, which is almost identical with carbolic acid, may account for some of the discrepancies in the results. The Russian tar produced no effect except sometimes in the dry stage, whereas, in lepra it is often very useful.

Baths, hot or cold, simple or medicated, saline or chalybeate, Turkish or Russian, are one and all useless or injurious in eczema, more generally the latter.† Sheridan is said to have remarked that man is not altogether an amphibious animal, and certainly eczema does not prove him to be one. In fact, it is one of the complaints in which the human skin will not bear too much steaming of any kind. Dr. Ross says, that in weakly persons suffering from lichen he has seen a fresh crop of papules break out after each warm bath, and I have observed the same thing in eczema. Dr. Lorry has noticed it in prurigo.‡ Vapour baths of dry air and sulphur baths proved in my practice still more injurious than the others. Still, there is no denying that baths with linseed, gelatine, quince seed mucilage, glycerine, and starch, seem to have been very useful in the hands of Mr. Startin, some of the physicians at St. Louis and other writers. Some of the continental surgeons make great use of baths, sometimes employing various kinds in combination; for instance, M. Bazin uses§ starch and sulphur or alkaline baths at the same time, prescribing along with them a vapour bath occasionally. Mr. Hardy also uses baths in eczema|| as does Hebra.

There is one way in which the sulphur baths may be occasionally very useful, and that is, as a rude means of diagnosis. The papular or pruriginous form of eczema is, like impetigo about the hands and feet, only to be discriminated with great difficulty from scabies; there is little to rely on except the presence of the acarus and the history of the infection. The latter is often obscure and the detection of the acarus is difficult enough to those not versed in such vexed questions, and not very easy to the most experienced. Eruptions on the mammæ in women, especially those who are suckling and who have had infected children; on the insides of the thighs, lower part of the belly, and on the knuckles in adults, and on the breech in infants, are of course suspicions, but they are not pathognomonic. Now a few sulphur baths generally do a great deal of good in eczema really resulting from scabies—for this is sometimes a complication and not a cause—whereas, in eczema proper, they are useless or set up irritation, which however disappears promptly when they are left off.

Mr. Alfred Pallar has given¶ a short, but very clear account of a mode of treating eczema by means of an impermeable dressing, which seems to answer very well in some cases of eczema of the limbs in old people. It was first brought into notice at St. Louis by M. Hardy, and consists in covering the parts completely with vulcanised india-rubber cloth, made of ordinary cotton cloth overlaid with a solution of caoutchouc and subsequently vulcanised. Hebra, who has tried the plan, had stockings, gloves, caps, &c., made of this cloth for his patients and found it answer very well. After a covering of this kind has been kept for a few hours on a patch of eczema the surface appears quite wet, and the fluid which collects on the skin in considerable quantity, emits a very penetrating odour. The application is not uncomfortable, inducing neither heat nor itching, and when sufficiently long continued, seems to have the effect of gradually removing all the symptoms. Some cases are mentioned by McCall Anderson in which old standing eczema was promptly and thoroughly relieved by the use of these impermeable dressings.

EXPERIENCES OF A REGIMENTAL SURGEON  
IN INDIA.BY C. A. GORDON, M.D., C.B.,  
Deputy Inspector-General of Hospitals.

## CHOLERA.—(Continued.)

THE same series of reports informs us that, in 1835,\* in addition to the personal inspection by the medical officers of the soldiers twice daily, as already described, "each non-commissioned officer received strict injunctions to watch the men of their respective companies closely, and to send them to hospital the instant they appeared to be in the slightest unwell;" and by those of 1836 we find it recorded that, on the occasion of the outbreak of the disease as an epidemic at Ghazepore in that year, the system adopted was of "dealing openly and fairly with the men, by explaining to them the vital importance of attending to the first symptoms of indisposition, and pointing out to them, when they reported themselves early, the success with which they are treated, and the utterly hopeless condition of their situation when they have neglected these precautions, and been brought to hospital in a state of collapse;" and Dr. Burke, commenting on these arrangements, observes that "it is of the highest importance every soldier and officer should know that, however slight the case may appear at the first moment of attack, the progress is rapidly onwards to a state over which we have no power; and, on the other hand, that most cases where the early or premonitory symptoms are attended to, the disease is to be cured like any other."

j. Among the measures of late years proposed in outbreaks of cholera among troops, the separation of those affected with that disease from their comrades, the removal of the men affected to a greater or less distance from barracks, and their distribution in larger or smaller bodies have deservedly been considered as among the most effectual towards the prevention as well as extinction of the epidemic. It is something to know that the importance of these measures has been demonstrated to, and acknowledged by, non-professional men, and has been included among the steps which are now authoritatively ordered to be taken on occasions of epidemics of this nature. Those of my readers who are acquainted with what has been written on the subject of sickness in the West Indies, must be well aware that for generations back, isolation of men affected with yellow fever, and removal into camp of the men affected have been periodically put in force; but from some cause or another, there appears to exist, even among professional men, an imperfect knowledge of the extent to which similar arrangements were formerly made in India on the occurrence of cholera as an epidemic.

That the plan of encamping men, on such occasions, was in force so long ago as 1825,† we have distinct mention made in the official reports of that date. For example, in the report of the 31st Foot for that year, we learn that "previous to the 20th December, the regiment had suffered much from cholera while stationed in Fort William; but, on being encamped on the open plain or esplanade, the disease seemed immediately to abate, and ceased soon after."

In the Annual Report of the Inspector-General in Bengal for the years 1826 and 1827, we read as follows:—"On the 30th December (1826), they (the 13th, 38th, and 47th Regiments) reached Pahanagah, and were encamped in a low jungle position, with high grass; but on the night of the 31st December, cholera in its worst form broke out among them, and for four-and-twenty hours had a most alarming appearance, when it suddenly disappeared on the moving of the camp to a dry elevated situation, and clear of jungle;" and two years afterwards we find Dr. Burke expressing himself in this way

while writing on the effects of this measure,\*—"The removal of the men to other quarters, or to tents, had in my experience here (Berhampore) and elsewhere, been of permanent benefit in choking or putting a stop to this disease, when"—he observes—"it was done in the proper and favourable season; but," as he stated, "in the hot winds the encamping the men was found to be attended with no advantage, but the contrary, as was proved this year." Thus, the fact is rendered apparent that Dr. Burke, while well aware of the advantages of encamping troops on occasions of epidemics of this disease, was no less alive to the possible evils by which the measure might be attended if injudiciously carried out.

In 1835 the same measure was again put in force, and is thus recorded by the Inspector-General,†—"Several cases (of cholera) having occurred among the soldiers' wives (of the 49th Regiment in barracks) the surgeon was induced to recommend that half the families should be removed to a distant, though unfinished room, towards the end of the lines;" and, it is added, "no case having occurred in the barracks after the removal, renders it more than probable that the atmosphere had lost its influence in that quarter." When, in 1842, cholera attacked the 29th Regiment, the corps was stationed at Chinsurah. Between 22nd of August and 8th November, the disease carried off 50 men, besides women and children. On the latter date the Regiment began its march towards Ghazepore, the sick, the women and children, proceeding by water; and the circumstance was noted,‡ that immediately on the march being begun, the disease, which had so long clung to the men, appeared to cease. No further case occurred. Finally, when in August, 1843, the same disease attacked the 39th Regiment at Agra, the corps was moved into camp, at a distance of some five or six miles from cantonments. It there remained ten or twelve days, and with the best results, although the weather was most unfavourable, and the ground in a bad state on account of rain (Report, 1843).

It is due to the officers who, in 1833, administered the Government of India to mention in these pages the fact that they had become fully alive to the necessity of issuing, under authority, a brief code of instructions to be followed on occasions when the disease should make its appearance. A Board of Health, as it was, called or, in other words, a Sanitary Commission was accordingly appointed, the recommendations of which, as conveyed to the Inspector-General by the Secretary to Government,§ are as follows, namely,—

"It was accordingly recommended that patients suffering from the disease be treated in a separate ward of the hospital, or in a distinct building.

"The bedding and bed-clothes that had been in use to be purified and fumigated; those that cannot be so, to be destroyed.

"Bodies of men who die were to be interred with the least practicable delay, being conveyed to the graveyard in the covered cart for the purpose, and the body to be, if possible, exposed to aspersion by a solution of chloride, or to fumigation by one of the disinfecting gases.

"As perfect a segregation of the troops as possible was to be secured on occasions of their having to march through infected districts, or where the corps alone is infected, and the district not.

"When the disease has broken out extensively in barracks, and circumstances will permit, the corps should be marched out, and encamped in a dry, open, and elevated position."

Such, then, are some of the measures in former times adopted, with a view to combat this most terrible disease; measures which, in several respects, are identical with, and in all calculated to be quite as effectual for their purpose as those that have of late years been proposed with all the importance of novelties.

## NOTES ON PHTHISIS PULMONALIS, &amp;c.

By R. LOCKE JOHNSON,

Visiting Physician to the Infirmary for Consumption and Diseases of the Chest, Margaret street, Cavendish square, W.

(Continued from page 482.)

## CASE IV.

T. C., male, æt. twenty-five, married. Two years ago had intermittent fever for three weeks, and been under Dr. Timms as an out-patient ever since. No family history. Lately blood in expectoration, *not* in red streaks, but the whole sputa, dirty and rusty. This mostly in the night after long fits of coughing. At other times the expectoration is frothy white. There is pyrexia and dyspnoea. General moist crepitation all over both lungs. The moist character is less marked at the back where the vocal fremitus is remarkably increased.

7th.—At the right side now the breathing has become tubular.

10th.—Left apex moist and there is loud cooing. Base dull on percussion with tubular breathing. Right apex moist, dull on percussion, base also moist, not so dull as apex. Dyspnoea excessive. Pulse, 100; respiration, 26; less thirsty.

R. Tinct. camph. comp., ℥ xx.;  
— Serpent, ʒss., aq., ʒj. ter die;  
Ol. morrhæ, ʒij., ter die.

Croton-oil liniment to be well rubbed into the chest. Last night spat a teaspoonful of blood. Pulse, 120; respiration, 28; still very thirsty; mouth dry; lips parched; tongue rather furred; bowels open daily.

12th.—Sounds the same, other symptoms also; thirst.

Camph. co., mxx.;  
Liq. am. aet., ʒss., aq. ʒj. ter die.

16th.—Pot. bic. et nit. aa gr., x., ter die.

18th.—Pulse, 120; respiration, 25. Urine throws down large quantities of lithates. The cough is less troublesome. No pain nor sweating. Feels stronger, walks better. No more hæmoptysis.

25th.—Same. Pulse, 120. Cough no better.

28th.—Feels the same. Right base now gives crepitation with bronchophony. Pulse, 120. Worse after dinner, flushes then very much and feels stuffed at chest. Appetite remains good; bowels regular; tongue slightly furred, brownish.

May 5th.—At both apices moist crepitus, and also right base. Left base hard and tubular. Tongue furred; patch of red in centre.

Sodæ hyphosphos., gr. v., aq. camph., ʒj., t. d.

9th.—Caught a cold.

11th.—Thinks he spits a little more frothy.

14th.—Spits scarcely anything in the day but a good deal at night. It is much thinner and more frothy. Auscultation the same. Both apices much creaking.

16th.—Auscultation nearly the same, but at one point of the left base deep respiration now seems to end with a crepitus.

He feels himself still improving and thinks he has gained flesh.

21st.—The last day or two expectoration in the morning has been greenish. Cough a little more troublesome. Other symptoms the same.

27th.—This patient continued to improve for another week, and then left the hospital to go to his home.

## CASE V.

E. T., male, æt. twenty-two. Married. Has one child. Last year had a cough; about Christmas got partial right hemiplegia when the cough got worse. Kept his bed four weeks from the hemiplegia. One brother and sister died of consumption. Has lost flesh. After the paralysis weakness and pain of lower limbs remained on movement.

April 3rd.—Complains only of severe pain in limbs. Worse on movement, and at night. Ankles and legs are

swollen. Scarcely any cough, but a little wheezing. The percussion note is dull on both sides of the chest. There is prolonged expiration and harshness of breathing at the left apex, with an increase of vocal resonance.

Potassi bic. gr. xx.;  
Vini. col chici., m x.;  
Inf. gent. ʒj. ter die.

14th.—Has lost the pains in limbs, and feels altogether better. Has no more cough nor wheezing. Appetite good. Tongue clean. Bowels regular, once a day.

Quini. dis., gr. j.;  
Tr. ferri. ses., m. xx., aq. ʒj., t. d.

18th.—Pain after eating. Mistismuth.

20th.—Complains of flatulence.

28th.—Feels better. No pain after eating. Appetite good. No cough.

30th.—Pain in chest. Sinapism.

May 5th.—On more careful auscultation several medical visitors being present, it was agreed that the percussion note was not materially deteriorated. At the apices respiration was equable, but the expiration on the left side a little prolonged.

He remained another fortnight rapidly progressing.

## THE SEWAGE QUESTION.

## SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XXXII.

## PARASITIC DANGERS OF SEWAGE IRRIGATION.

ENTOZOIC diseases have always an external origin, and are generally caused by food or drink infected with the ova of parasites, or with the parasites in a larval condition,—the food or drink being in its turn infected directly or indirectly by excremental pollutions. In some cases, as with the protozoa and the nematoid worms, the ova or the mature parasite may gain access to the body of man and at once cause disease of a more or less serious character through the water which we drink, or some raw vegetable which we eat, infected with sewage. Water-cresses, celery, lettuce, endive, and other such vegetables eaten in a raw condition, may after recent sewage irrigation, convey the agents of parasitic disease. At other times, as with the cestoid forms of entozoa, helminthic disease is caused by the use of meat infected with the larvæ of parasites that have had their origin in sewage or excremental matters present in the green fodder, or other food upon which the animals have fed. A single individual infected with tape-worm will discharge from his body millions of ova, every one of which is capable of producing a measles, as it is called, in the flesh of an animal, and this in its turn a tape-worm in man. As we have elsewhere remarked, "sewage contains myriads of ova of intestinal entozoa,—every segment of tape-worm discharged from the human body being crowded with them, and if distributed with sewage upon the land, will become attached to the grass and other green fodder which is grown thereon. This is eaten by cattle, whose bodies quickly become infected with the parasite in its larval condition, and thus the measly meat becomes the agent of disease in our own

bodies. At present the distribution of these ova, and their access to the bodies of herbivorous animals is entirely a matter of accident; but make it a matter of certainty, as most assuredly you will by distributing sewage upon the fodder-producing land, and the consequences must be serious. Dr. Cobbold, who is our highest authority on this subject, has published an essay, warning the public of the danger of this method of distributing town sewage; and he has hinted at the probable introduction into this country of a terrible helminthic malady (*Bilharzia*) which is now common in Egypt, Africa, and the Mauritius, and which would assuredly be propagated throughout the land by this dangerous scheme of irrigation. "Have the kindness," he says, "to observe that every colonist returning from the Cape is liable to bring this parasitic treasure with him as a guest indeed, dwelling in his blood, and feeding on his life stream. In the advanced stages of the malady, the afflicted individual must frequently evacuate the eggs and their contained embryonic larvæ, which are thus conveyed into the ordinary receptacles of such voidings. There let them remain, or convey them into a cesspool, and no harm follows. If deemed preferable, you may transport them along with myriads of other human parasite eggs and larvæ into a common sewer, and thence into the sea; still entozoologically speaking, no harm follows. Here, however, let me invite you to pause, for if, without due consideration, you adopt any one of the gigantic schemes now in vogue, you will scatter these eggs far and wide; you will spread them over thousands of acres of ground; you will place the larvæ in those conditions which are known to be eminently favourable for the development of their next stage of growth, you will bring the latter in contact with land and water snails, into whose bodies they will speedily penetrate; and in short you will place them in situations where their yet higher gradations of non-sexual growth and propagation will be arrived at. After all these changes, there is every reason to believe they will experience no greater difficulty in gaining access to our bodies here in England than obtains in the case of those same parasites attacking our fellow-creatures, whose residence is found in Egypt, in Natal, in the Mauritius, or at the Cape. In a natural history point of view, it would not be an altogether singular result if, twenty years hence, this parasitic malady should be as prevalent in this country as it is now known to be in particular sections of the African Continent. Foreseeing the possibility, not to say probability, of this contingency, am I not right," he says, "after years of long study, to raise my voice in the hope of preventing such a disaster."

Nor is it unlikely that the trichina may be distributed in the same manner, for it swarms in the intestines of those who have just become infected with it, and may be discharged into sewage and scattered upon the land, and eaten by creatures whose flesh will give it back to us again. No one, in fact, but the helminthologist, can say what particular parasite may not be distributed and propagated by this dangerous agricultural process. "May we not indeed," as Dr. Cobbold observes, "but too reasonably conjecture that the wholesale distribution of tape-worm eggs by the utilisation of sewage on a stupendous scale, will tend to spread abroad a class of diseases, some of which are severely formidable? So convinced am I," he says, "of the truth embodied in an affirmative reply to this latter query; so certain am I that parasites are propagated in this particular way; so surely do I see unpleasant results if no steps are taken to counteract the evil, that I feel my-

self bound to speak out boldly, and to produce no uncertain sound in the matter which most closely concerns humanity! The whole question is in truth of vast hygienic importance." But the Editor of the *Lancet* does not appear to entertain this opinion, for in a leader of the 4th of February last he thus expresses himself. "Dr. Spencer Cobbold is an acknowledged master in the science of Helminthology, and as long as he speaks in that capacity we sit humbly at his feet. But when he sets himself up for an oracle on sewage irrigation we have a fair right to examine the facts upon which his reasoning is based, and to express our opinion with an authority at least equal to his own. We are, therefore, ready to admit that Dr. Cobbold's history of tape-worm is in the main correct. Briefly, we have no reason to doubt that the ova are discharged in human excrement; that they occasionally by some means or other, get into the flesh of cows, calves, oxen, and pigs; that when they do so they appear as 'measles'; and that when such flesh is taken in an uncooked form by man, tape-worm is again produced. But whilst this may be true it by no means follows that butcher's meat is ordinarily 'measled,' or that a larger proportion of 'diseased meat' is produced on sewaged than on other farms." This is a remarkable jumble of inconsistencies; for if all tape-worms in the human subject have had their origin in measly flesh eaten by man; and measly flesh has always come from the ova of tape-worm: eaten by the animal; and the ova so eaten have always been discharged with human excrement, it follows, as a matter of necessity, that wherever such excrement is most frequently found upon the pasture or green fodder eaten by cattle, there the animal must be most liable to have its flesh infected with measles. Now sewage is a liquid which is always charged to a greater or less extent with such excremental ova, and therefore the farm which receives it upon the land must be more liable to produce measly meat than the farm which has none of it; for in one case the infection of the animal is an accident, and in the other almost a certainty. Abundant evidence has been given of the greediness with which cattle will feed upon the succulent pasture of ground irrigated with sewage. Mr. Mechi states that not only have cattle no objection to sewage upon grass, but they like it so much that they follow the hose and will feed upon the grass while it is still wet with sewage. Mr. George King, a civil engineer, who has laid out several sewage farms was asked by the Parliamentary committee on the sewage of towns,—“at what time after the application of sewage do cattle feel inclined to feed upon the sewaged land; have they any objection to it at any time?”—to which he replied, “I think they will feed upon it immediately, even while the sewage is upon the ground; they seem to relish it at once.” Mr. Tregelles, who gave evidence before the same committee, said “perhaps I need hardly state to the committee that cattle eat grass with great avidity after it has been watered with sewage manure: it is remarkable, indeed, how they will eat the land closely when they will reject spots in the field upon which their own droppings have fallen and will not touch it; but they eat the grass close to the ground where sewage has been placed.” Mr. George McCann also, in answer to the question whether cattle have any objection to eating this grass after the application of sewage? said, “not the slightest; for I have seen horses, cows, and sheep eat it most eagerly before the sewage has been upon it forty-eight hours,—more so than on any other part; in fact they prefer

he land watered in that way." And so strong was the testimony of farmers on this head that the select committee in their final report alluded to it, saying that "the evidence proves that cattle of all sorts appear to prefer sewage grass to all others, and will eat it within a few hours of its being dressed with sewage." In proof of this they refer to the evidence of Dr. Angus Smith, Mr. Lawes, Mr. George King, Mr. Edwin O. Tregelles, Mr. George Henry Henderson, Mr. George McCann, and Mr. Francis Wyley. At Carlisle, where the pasture land is constantly irrigated with sewage, the sheep and cattle feed upon it continuously. At Penrith a very large stock of cattle is kept upon the land to graze down the abundant growth of grass upon the meadows which are irrigated with sewage; and at Croydon the practice used to be to irrigate the land for three or four days and nights together two or three times for each crop, and when the grass has got a sufficient head, to stop the application and turn the stock upon the land, where they remained until the grass is closely eaten down; they were then removed, and the land was irrigated in a like manner. Even when the grass is cut down and carried to the sheds where the cattle are kept it is often wet with sewage. There is no difficulty, therefore, in understanding how a sewage farm is more likely to produce measly meat, than a farm not sewage. It may well be that the butcher and the veterinary surgeon are not able to detect the measles in the meat, for unlike the measles of pork, they are very small in veal and beef, and are but sparsely distributed; so that nothing but a thorough anatomical dissection would lead to their discovery. That they are present, however, is abundantly proved by the existence of tape-worm in man.

Another serious consequence of sewage irrigation is the spread of rot among sheep; for experience has shown that a damp and sodden condition of the ground is peculiarly favourable for the production of the liver fluke (*Distoma hepaticum*) of sheep,—the method of development being as follows:—Ova are passed from the gall bladder of infected animals into the intestines, and so upon the land; finding a moist situation they are soon hatched into ciliated embryos, which swim about, and become developed into cylindrical sacs of minute hydatids. These attach themselves to some small mollusc, as snails and slugs. In wet weather the infected snails crawl upon the grass and are eaten by the sheep; and then the hydatid speedily changes its condition and becomes a fluke. Upon dry land the ova and its progeny perish, but in wet lands they retain their vitality, and often create a pestilence, sweeping off whole flocks of sheep. The dangers, therefore, of sewage irrigation, even in this particular, are not undeserving of attention; for assuredly it is a means of producing the very conditions which are required for fluke disease.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.  
TUESDAY, NOVEMBER 28, 1871.

MR. CURLING, F.R.S., President, in the Chair.

ON A CASE OF UNILATERAL ATROPHY OF THE TONGUE.

BY WM. FAIRLIE CLARKE, M.A., F.R.C.S.,  
Assistant-Surgeon to Charing-cross Hospital and to the Central London  
Ophthalmic Hospital.

Mrs. H—, æt. forty five, became aware of a tumour in her right breast in the spring of 1869. In February, 1870,

she showed it to Mr. Hume, of Devonshire street, Islington, and he recommended that it should be removed at once, as it had all the characters of a malignant growth. It was accordingly excised on the 16th of February. The wound healed slowly, but satisfactorily. On April 15th she complained of cough and slight dyspnoea, the latter only noticeable after exercise. Under treatment the cough soon disappeared, but the dyspnoea continued. On the 3rd of October Mr. Hume was called suddenly, and found her suffering from a deep-seated pain on the right side of the head, of a periodic character, returning each night between 1 and 2 o'clock A.M., and rendering her for some hours incoherent and unmanageable. Many remedies were tried; but the only thing which gave her relief was morphia in grain doses. It was at this date that the atrophy of the tongue was first noticed, though it was not then so marked as it afterwards became. On March 29th, 1871, Mr. Hume was again urgently required to attend, and found the patient suffering from all the old symptoms, but in an aggravated degree; and in addition there was an alarming dysphagia, together with paroxysms of suffocation, which recurred about three times in the twenty-four hours. On being asked to protrude the tongue, she always appeared unable to do so at first; and, on the request being repeated, would reply, "Wait a minute." Then, after a few moments' deliberation, she put it out very slowly. The tongue was puckered and crimped along its whole right side from base to apex, though these appearances were the most marked at the anterior two-thirds. An actual loss of substance had taken place, but it was bounded exactly by the median raphe; and the contrast between the *plumpness* of the left side and the shrivelled aspect of the right was very striking. When it was protruded, there was no deviation to either side. Articulation was slow and difficult. There was great pain along the right side of the neck, with a certain fulness and turgescence of the vessels; but no tumour could be felt in any part of the mouth or neck. Together with these symptoms there was general cachexia and great prostration of strength. From this time the dysphagia and dyspnoea gradually became worse; and on the 7th of June, in one of the attacks of suffocative cough, the patient died. At no time during her illness had there been any paralysis of the extremities, and her intellectual faculties remained clear throughout her whole illness.

Unfortunately no autopsy could be obtained; but, looking at all the circumstances of the case, the author thought there was good reason to believe that the ninth nerve on the right side was involved in a secondary cancerous tumour, such tumour being situated either within the cranium or at the upper part of the neck, and pressing upon the right hypo-glossal nerve, and more or less implicating the pneumogastric and glosso-pharyngeal nerves as well.

The author proceeded to compare with this case two other instances of well-marked unilateral atrophy of the tongue: the one related by Dupuytren in the "Leçons Orales" (lecture on Hydatid Tumours); the other by Sir James Paget, in the third volume of the "Transactions" of the Clinical Society. The experience of Romberg and of Bidder was adduced to show that this remarkable condition of the tongue may be produced by a lesion of the ninth nerve; and to establish the same point the author related an experiment that he had made. On Oct. 25th he divided the right hypo-glossal nerve in a rabbit, and took out a piece about a quarter of an inch in length. Immediately after the operation, and during the whole time that the animal was under observation, the tongue was strongly protruded to the right side. On Nov. 27th the rabbit was killed. It was found that the nerve had united by a soft gelatinous and highly vascular substance, of about twice the ordinary calibre of the nerve. The right side of the tongue, along its posterior half, was slightly wasted and flattened.

The preparation was exhibited; and an outline sketch, illustrating the case which had been related, also accompanied the paper.

An interesting discussion followed in which several Fellows took part.

CASES OF INTER-MENSTRUAL OR INTERMEDIATE  
DYSMENORRHEEA.

BY WM. O. PRIESTLEY, M.D.,  
Professor of Obstetric Medicine in King's College.

THE author pointed out that, although much had been written concerning dysmenorrhœa, and several forms of it had

been described in accordance with the pathological views taken of its causes, the description of the several varieties was ordinarily limited to the time of the catamenial period, with the two or three days additional which may precede and follow the menstrual flow. From time to time, however, cases of a more obscure kind presented themselves, in which the chief suffering is remote from the actual menstrual period, but comes on, nevertheless, with the same punctuality, and is probably dependent on organic changes associated with the production of the catamenia. Probably other practitioners had observed like instances, as they were not uninfrequent, but as the author had met with no description of them, he brought the subject before the Society as a fragmentary contribution to the pathology of uterine affections, which might possibly evoke further elucidation by discussion.

In all the cases detailed severe pain was experienced by the patients midway in the menstrual interval. The pain commonly came on about fourteen days after a catamenial period, and, after lasting a variable number of days, ceased before the supervention of the next expected period. In one case, the pain, beginning midway in the interval, ran into the following monthly period, and was relieved by its flow. The suffering was constantly referred to one or other ovarian region, and in three cases out of four marked tumour, or thickening from old adhesions, was found in that locality.

The reason for the occurrence of pain in the inter-menstrual period, and with such regularity, was not, in the present condition of our knowledge, perfectly obvious. A study of the physiological and pathological conditions left little doubt, however, that it was due to perturbations in the functions of "spontaneous ovulation" habitually going on in the ovary. Hypertrophy of the structure of the ovary, or thickening of its indusium, would lead to undue vascular excitement, and impede the advance of ova to the surface in their attempts to obtain maturity. It was not unreasonable to suppose, from all the known facts of the case, that preparation for an approaching period began in the ovary ten or fourteen days before the occurrence of the monthly uterine discharge, and if the initial steps in the process of ovulation were opposed by certain pathological conditions, pain would ensue. Nay, in the absence of distinct organic change, it might readily be imagined how special irritability in the ovary would cause an unusual amount of disturbance whenever there was occasion for the exercise of fresh activity in the organ. This latter class of cases would partake more or less of a neuralgic character.

The treatment would depend on the pathological condition as ascertained by examination. The pain being only a symptom, it would be needful to inquire into the cause; and if there were tumour, or thickening depending on former inflammation, absorbent remedies would be indicated. If no organic change of structure could be detected, anti-neuralgic remedies, such as quinine, iron, and arsenic, would best answer the purpose of cure.

## MEDICAL SOCIETY OF LONDON.

DECEMBER 4TH, 1871.

DR. ANDREW CLARKE, F.R.C.P., President, in the Chair.

DR. BROADBENT exhibited

MORBID SPECIMENS FROM A CASE OF APOPLEXY FOLLOWING DISEASE OF THE KIDNEY.

One kidney had undergone granular degeneration, the other was not much changed. The heart was atrophied, and in the left hemisphere of the brain, there was a large irregular cavity, the minute arteries were also hypertrophied. The woman had recovered from a former attack of hemiplegia, and had gone on pretty well until six months ago, when she suffered from general weakness, pain in the head, indigestion, &c. The pulse gave at first an impression of being feeble, but it was not so, it could be rolled under the finger, and when pressed on above, continued to give a thrill to a finger placed below. The area of the heart's dulness was increased, the apex beat below and to the left of its usual situation. At the inter-ventricular septum, the 1st sound was reduplicated, at the apex the 1st sound only was heard. The right ventricle produces the first portion of the reduplicated sound, the left ventricle the second, owing to its meeting with a momentary resistance.

The patient was pregnant, but did not know it till just before death, as she had menstruated regularly and was unwell at the time of dying. She was seized with convulsions, coma, rigidity and paralysis of the left limbs, hæmorrhage came from the middle cerebral artery, and the cavity was situated external to the motor ganglion and motor tract.

DR. BROADBENT thought the rigidity was due to a disturbance, not a destruction of the motor ganglion and motor tracts.

In answer to a question from DR. HUGHLINGS JACKSON, he said that there was no pulmonary apoplexis, the tongue was bitten.

THE PRESIDENT remarked that the case was well told, and the points open to discussion were:—I. Is the thickening of the arteries due to poisoned blood? II. Is the reduplicated sound due to the lagging action of the left ventricle? III. Is rigidity due to disturbance, not destruction of the motor ganglion?

MR. WALTER COULSON exhibited

TWO PATIENTS WITH SYPHILITIC ULCERS CURED BY SKIN-GRAFTING.

The first patient had suffered severely for three and a-half years from the effects of malignant syphilis, there had been ulceration in the face, loss of portion of the nose and one extensive ulcer on the leg. He was given at the Lock Hospital as much as 80 grains of pot. iod. three times a day, the ulcers on the face healed, but the leg did not. He was treated at Birmingham with mercurial baths, but without much success, on his return, the man was treated with bark and nitric acid, and the surface of the wound was granulating healthily, the limb was placed in a straight splint, but on October 3rd, five pieces of skin were taken from the left arm about the size of a pin's head and transplanted. October 16th, five more pieces were grafted. November 1st, all the five last grafts had taken. On November 20th, the ulcer had healed with the exception of a small spot. The second man had been suffering for two and a-half years from a large syphilitic ulcer of the size of a cheese plate, and had taken pot. iod. 70 grains three times a day. On October 3rd, skin-grafting was done as in the first case with great success, the medicine being left off when the grafting commenced. This plan of treatment was recommended in the chronic stage of the disease when the ulcer was covered with healthy granulations.

In the discussion which followed, MR. JABEZ HOGG recommended bromide of potassium in syphilis.

THE PRESIDENT called attention to this as if it was as useful as iod. pot. it was important to know it, as the latter was not always well borne.

DR. BROADBENT who has specially experimented in the bromides, said that their action was quite contrary to that of the iodides.

MR. DE MERIC condemned the use of bromides when the iodide could be given. He thought that iod. pot. bro. was pushed too far, as it interfered with the sexual capacity of the patient, he had advised a little mercury combined with the iodide. He had also transplanted in some cases, but had failed.

DR. HUGHLINGS JACKSON then gave the particulars of a case of

DISEASE OF THE RIGHT LOBE OF THE CEREBELLUM, TUMOUR WITH CYST.

The striking point in the case, was the existence of double optic neuritis (observed by Mr. B. Carter as well as by the author), without obvious impairment of sight, there was severe headache and urgent vomiting. Very remarkable intermissions in these symptoms occurred, the patient seems to be quite well in the intervals. Later palsy of both sixth nerves occurred one before the other, and there seemed trifling difficulty in walking, but there was no limb affection. The author remarked in the several symptoms of the case, and particularly urged that diseases of the cerebellum caused neither loss of sight or deafness. It frequently—if tumour—led to double optic neuritis, consequent on this blindness occurred in a round-about-way, and he imagined through the intermediation of the vaso-motor nerves.

A discussion ensued, in which the President, Dr. Broadbent, Dr. Allen, Chapman, and Mr. Jabez Hogg took part.

THE MEDICAL SOCIETY OF THE COLLEGE OF  
PHYSICIANS OF IRELAND.

THE above Society met on Wednesday evening last in the hall of the College. The Chair was occupied by SIR DOMINIC CORRIGAN, BART., M.P.

DR. STOKES communicated to the Society

SOME NOTES ON THE TREATMENT OF SMALL-POX.

In entering on the subject, DR. STOKES observed that the extinction of small-pox in Ireland, which was improperly attributed to the prosecution of vaccination, was shown not to be due to that cause, because most of the existing population had attained manhood before the vaccination system was introduced, and for many years afterwards inoculation was covertly practised, a proceeding which was fostered by the fact that the authorities took no notice of it, unless it was reported to them by the medical man himself. Since 1848 the type of small-pox in Ireland had been always of a low and typhoid type. In the sthenic type vascularity of the skin was much more fully developed than in the asthenic form, and therefore pitting was much more frequent than after the type of the disease had altered. He remarked that this condition arose more or less from the impossibility of keeping the skin of the face and hands as moist as the parts covered by the bed-clothes. He alluded, while on this part of the subject, to the case of a young lady in whom, for the purpose of saving the eyes, he had applied poultices over the orbits, and, as a result, the whole of the part covered by the poultices was perfectly free from pitting, while the rest of the skin was deeply seamed. Since then he had uniformly employed the system of covering the face with poultices, and with the very best results. MR. STOKES proceeded to quote the case of a patient in whom, as the prominent symptom, was headache; he had applied a large number of leeches to the temples, and the result was, that while the pustulation was largely developed on the body, the face and head escaped almost wholly. He considered from this and other experiences that depletive treatment of local skin affection would be of the greatest advantage. Dr. Graves narrated a case in which a man, who had been laid up in hospital for disease at the knee-joint, which necessitated mercurial strapping, had been attacked with small-pox, which profusely covered the whole body, but did not touch the knee at all. These facts lead us to the treatment of the warm bath practised by Hebra, in which the conditions of exclusion of air, and the securing of constant moisture are secured. DR. STOKES described at length the case of a patient whose condition from confluence of the pustules was, in the words of DR. STOKES, that of "one ulcerous sore," and who suffered from terrible delirium in consequence of the pain he suffered from contact of the pustules with the bed-clothes. As a last resource the warm bath was tried, and the effect of it was "miraculous;" almost in an instant the pain and delirium ceased, and from that time forward his recovery was constant and unchecked. DR. STOKES spoke in the most eulogistic terms of the bath treatment, which he could say was productive of no danger, whatever, and enabled the necessary stimulant treatment to be carried on without intermission.

SIR DOMINIC CORRIGAN reiterated the remarks of Dr Stokes that the efficiency of vaccination legislation was altogether marred by the fact that it only provided for the vaccination of the future generation. He had made many attempts to impress this view upon law givers, but hitherto without any success. He considered that vaccination should be recognised as one of the necessary qualifications of public employment, and that the onus of insisting on this qualification should rest not on the poor man, but on the employer. SIR DOMINIC CORRIGAN stated that inoculation was regularly practised by persons who came round to a village beforehand, arranged for an occasion, at which the children were deposited in a room, and returning on that occasion the children were there and then inoculated, no person being present who could swear to the transaction. Referring to the latter part of Dr. Stokes's paper, SIR DOMINIC CORRIGAN remarked that it was fully corroborated by the fact that no one ever saw a small-pox pustule in the axilla. He remarked that the dressing of gutta-percha solution was very useful on the second day of the eruption, when it served the purpose of excluding air and including moisture, but very bad on the eighth day, when it confined purulent secretions.

DR. BEATTY considered that the apparent failure of vaccination to stamp out small-pox has arisen from a failure in the efficacy of the vaccine virus, because of its not having been

sufficiently frequently renewed from the cow, and as in all other matters Nature exercises a power to bring products round to that simplicity, so he believed that the virus had lost its efficiency by want of renewal.

DR. BRISKE, Medical Registrar, was utterly at issue with Dr. Beatty in his view. He reminded the Society that the passing of the virus through any number of persons did not alter the complete development of the pustule. He considered that in any case in which a perfect vaccination mark existed, the protective effect was as good after twenty years as at the moment of vaccination. The Compulsory Vaccination Act as it exists at present is simply inoperative. It had done much good, but it was now utterly useless, unless amended, to protect the public against the access of the disease. The returns made by the Registrar-General weekly, were perfectly unreliable on this subject, because the small-pox beds were not within the district at all, and the deaths in them were not returned to the Registrar-General at all.

DR. HENRY KENNEDY alluded to the fearful form of small-pox which recently existed in London, from which the mortality exceeded 50 per cent. In Dublin it had not as yet gone beyond 18 or 20 per cent. He was sorry to say that he had seen deaths in patients being thoroughly marked by vaccination. He considered it of great importance that, as in typhus and other fevers, it was quite necessary to take the case in the first stage, and treat it vigorously in anticipation of the ultimate cause of the disease.

DR. GRIMSHAW said he was now engaged on a series of experiments as to the effect of occlusion from air and light by strappings, but he was not as yet able to state the result. He had been using poultices very extensively for the purpose of avoiding hard crustation, and so far it appeared a successful line of treatment. He had also employed leeching in more than half his cases. Up to the present day, out of about 160 cases, he had only seen two which came under the provisions of the Compulsory Vaccination Act, and out of all the deaths numbering over thirty, or about 18 per cent., only three deaths occurred in which the vaccination marks existed.

DR. GORDON considered that the principle communicated by Dr. Stokes could be carried out to a more useful extent. Most of the cases in the present epidemic were marked by tracheal and laryngeal symptoms, and he had found the depletive system very efficient in the treatment. In view of the large number (300) which had passed through the Hardwicke Hospital, he was of opinion that in this epidemic the secondary fever was very slight, and the cutaneous inflammation little marked. He had in such cases used the warm bath with great satisfaction.

DR. STOKES considered that the least that could be said for the warm-bath treatment was that it completely obviated the chances of septic poisoning, and the injurious consequences of continued pain.

**Geology of the Pyrenees.**—M. Garrigon describes a curious region in the Pyrenees situated between Salies de Béarn, Dax, and Bayonne. It consists of a series of hills constituted by the undulations of the cretaceous formation, crowned with an alluvial deposit exclusively composed of red clay and quartz pebbles which may be referred to the pliocene period. Most of the depressions produced by these undulations are at present filled with peat, which from its horizontal position shows that each of these spots was occupied by a lake now dried up. There are forty-five of these places, called *barthes* by the inhabitants, around Salies, alone. In one of these M. Garrigon caused an excavation to be made to an average depth of eighty centimetres, at which he was stopped by finding a regular floor, made of trunks of trees rudely split into boards, and resting on forked piles, simply consisting of pointed trunks, with the upper branches lopped off, so as to leave a support. There were also beams from three to eight yards in length, and all this woodwork was ingeniously joined together by turning the knots and other irregularities to account. The piles were between two and four yards long, and there was no doubt of their having been fashioned with sharp instruments and chiefly metal hatchets, and from the depth of the notches made, there was every reason to suppose that the metal used was iron. In the midst of a thick and glutinous peat, fragments of planks sharpened off at their ends were found, together with a wooden lozenge exactly resembling a latch still used in the country for doors. Immediately below the flooring, which by means of soundings taken at different places, was found to extend over several acres, water was discovered, which prevented any further excavation being pur-

sued. The country around these ancient lakes is studded with tumuli, where articles have been found belonging to the period when metals were used and the dead burnt.—*Globe*.

WEDNESDAY, DECEMBER 20, 1871.

### HOSPITAL OUT-PATIENTS AND PROVIDENT DISPENSARIES.

THE agitation of last year and previous years, which has hitherto been confined to the ranks of the medical profession, appears at length likely to become a national question. The charities of the metropolis have long been known to be far more extensive than is compatible with the welfare of the poorer classes, who, indeed, of late years have had their *morale* seriously lowered by the multitude of temptations to become beggars and idlers, instead of steady workers in the “struggle for existence.” Ancient Rome fell, when the citizens began to care only for lust and theatres; and the recent rage for charitable interference with the working classes, bids fair to convert a large proportion of the population of London into pauperised wretches, fit only to idle about, smoke, drink beer, and haunt the hospital, the workhouse, and the various other alms-giving institutions of “Modern Rome.”

The absurd facilities given by stupid guardians, too, by means of out-door relief, have, perhaps, more than anything else, tended to produce that amount of pauperism and dependence, which is so painful a feature of London life at this moment. The present generation seems to have well-nigh forgotten the axioms laid down by all writers on questions of poverty, after the inquiry of 1834, which showed so clearly the injury done to the wage-receiving classes by out-door relief. Such relief, it was then shown, tends to lower wages and damage the status of the lower classes very greatly. Unfortunately, our London Boards of Guardians are mostly composed of shopkeepers and employers of labour; and it is their interest to keep down wages, which they do at present so greatly by encouraging out-door relief and other encouragements to idleness.

Sir C. Trevelyan has well said that medical relief is perhaps the most dangerous of all, since when given gratuitously to any great extent, it reaches classes which would never be reached by any other form of charitable dole. Engineers and artisans, in receipt of large wages, are well-known to think that it is needless in London to think of ever paying for medical advice for themselves or families; and, in not a few cases, it is said, that the wives and daughters of well-to-do citizens have been known to dress themselves for the occasion, and appear at the hospital desk of some famous practitioner, in *formâ pauperis*, when living in luxury and splendour at home. Facts, such as these, have made it said by Dr. A. P. Stewart, that “the hospital out-patients’ department is the first step to the workhouse, whilst the Provident Dispensary is the first step to the savings’ bank.” The love of all that ennobles mankind makes us dread, lest poverty should become degraded, by making the poor and ill-educated believe that they have only to pray to the rich and humble themselves sufficiently, in order to receive all that they require. If England is ever to become as happy as she is powerful, it must be by means of education of its poor; and one of the most essential parts of all education for the poor is that which teaches the wage-earning class that labour and self-help is the only legitimate means of arriving at independence in a truly free state.

At the meeting, so ably presided over by Mr. Smith, M.P., last week, and which was under the auspices of the Charity Organisation Society, it was clearly shown by Mr. Fairlie Clarke and by Dr. Meadows, that medical charity in London is now doing serious evil both to the population of that vast city, and also to the medical men, whether consultants or general practitioners. It was asserted, and not shown to be untrue, that some 750,000 *individuals* annually avail themselves of the medical charities of the metropolis. There are some fifty free dispensaries in London; and Mr. Smith, M.P., and others contend that all of these should *at once* be converted into Provident Dispensaries, since the really necessitous poor are at present able to avail themselves of the new Parish Dispensaries, which are being everywhere constructed under the provision of Mr. Hardy’s Act. The meeting was so influential that we may conclude that the matter is in a fair way of being gone into, and we congratulate our professional brethren of London, and their patients also, in the prospect of a speedy arrangement of the present disgraceful state of affairs in the metropolis.

With regard to out-patients of hospitals, it is the opinion of Sir C. Trevelyan that all unfit persons could easily be hunted up at their own homes, by the aid of the Charity Organisation Society; and it is further added that all medical officers of public charities should receive some stipend as they do abroad, and that the number of new cases seen by each officer should be limited to some twenty or thereabouts. Mr. Stansfeld promises early legislation on this important question; so that some of us may live to see better days, both for the public and for our own profession in London and in other English cities. In Ireland these matters have long been better understood, and there is probably not so much room for improvement. The only serious objection made to the rational proposition laid down by Mr. Smith and others, was made by Dr. Rogers at the meeting referred to. Dr. Rogers thinks that the main evil in London and through-

out England is the miserable position of the Poor-law Medical Officer, and states that the average wage of a vast proportion of the labouring classes (12s. a week) is too low to enable them to think of self-help. But alas! Dr. Rogers seems to belong to the same school as his brother, the Oxford Professor, who speaks so constantly of the injustice of the present state of *political* matters, instead of *occasionally* adverting to the real difficulties of the question, which we have alluded to; and as disclosed by the Poor-law Commissioner of 1834. Self-help is the gospel of the poor, and charity is, when extensive, the greatest of all enemies to the working classes. If Dr. Rogers would read the Blue book for 1834, he would realise what we mean. By all means raise the position of the Poor-law Medical Officer; but let the whole question be discussed at once.

#### PROSECUTION UNDER THE MEDICAL ACT.

VERY recently we recapitulated the facts of a prosecution instituted in Leicester against a chemist named Lakin, for practising as a surgeon, and signing a certificate with the letters M.D., U.S. In defence, one of the sham diplomas of the University of Pennsylvania, which can be bought in London as readily as a sugar-stick, was produced. The magistrates reserved their judgment, which they have since pronounced. In their summing up of the case they say:—"A witness named Crick was called on behalf of the defendant, who was in the possession of a similar diploma to that of the defendant, dated April 27, 1867, and he stated that such diplomas are granted without any personal examination by the Professors, or any attendance at the lectures of the College, although the diplomas recite that they have been granted after the applicant for the degree has attended two full courses of Medical lectures, and passed a successful examination in each department of study 'before us, the Professors of the College.'"

The Bench cited precedents which are worthy the notice of the Profession:—"In *Ladd v. Gould*, the defendant had used the word 'Surgeon,' followed by the words 'Mechanical Dentist,' on the side of his door, and the justices had dismissed an information charging him with having used the title of 'Surgeon.' The Court of Queen's Bench held that it was a question of fact for the magistrates to decide, whether by the use of these words the party proceeded against was guilty of an offence against the statute; and Lord Chief Justice Cockburn said that there was not, in his opinion, any false pretence in using the word 'Surgeon'; that he should have come to the same conclusion as the magistrates, as it was like the case of persons calling themselves 'Surgeon-dentists' (or, as Mr. Justice Cramp-ton remarked, 'Surgeon-chiropodists'), but that there was evidence upon which the magistrates might have come to either conclusion, although, in the opinion of the Court they had arrived at a correct one. In the remaining case of *Ellis v. Kelly*, it appeared that the defendant, who was a duly registered Surgeon, had used the prefix of 'Dr.' to his name for some years before the Medical Act; that he was in possession of a diploma as a Doctor of Medicine of a German university; but that such diploma was not proved to be genuine. The justices had dismissed an information charging him with having used the title of Doctor of Medicine. It was held by the Court of Exchequer that the word 'Doctor' must, under the circumstances, be taken to mean a Doctor of Medicine; that a

person falsely calling himself a Doctor of Medicine (per Baron Bramwell) would be liable to a penalty, although he was in reality a Member of the College of Surgeons or of the Apothecaries' Company, and so registered; but the words 'wilfully and falsely' meant 'wilful falsity,' and that the possession of the foreign diploma, although not proved to be genuine, so far justified the defendant in using the prefix 'Dr.'—as he had done before the Medical Act was passed—as to exonerate him from the charge of having 'wilfully and falsely' assumed that title."

It is rather singular that there is no reported case of a successful prosecution under Section 40 of the Medical Act.

The magistrates, acting on these precedents, while they expressed regret that the law did not afford protection to the public against persons practising under fraudulent diplomas, considered themselves bound to dismiss the case.

It is very satisfactory to know that this, the last of a series of abortive prosecutions under the Medical Act, will not stop here, for a case for an appeal was obtained by the solicitors for the prosecution, and the subject will thus come before the Queen's Bench.

There is one point in this and in other cases, which seems to have escaped notice, and which, we imagine, would bring the prisoner within the operation of the penal clauses of the Act.

The 37th clause of the Act enacts that "no certificate required by any Act now in force, or which may hereafter be passed, from any Physician, Surgeon, Licentiate in Medicine or Surgery, or other Medical Practitioner, shall be valid, unless the person signing the same be registered under this Act." This clause does not, it will be observed, impose any penalty. It simply invalidates the certificate, and the prisoner in this case (who did give such certificate) was not open to punishment for doing so. But it seems to us that a person signing such certificate does an act which, inasmuch as it cannot be legally done by any other than a registered practitioner, involves a "wilful and false pretence" that he is registered.

For instance, let us take a parallel case. Suppose that there were no law to prevent any person putting on the uniform of a policeman, unless he makes a false pretence of being a member of the force, the law could not punish any person simply for adopting the uniform. But suppose the law declared that no one except a policeman should arrest a cabman, the pseudo-policeman would, in doing what no one but a policeman could legally do, render himself liable for the "wilful and false pretence" just in the same way it would seem that a quack who may have been able to keep within the letter of the law by calling himself F.R.A.S. or B., Member of the Royal College of Physicians and Surgeons, would bring himself within its reach if he were to do that which no one but a legal practitioner is authorised to do.

#### THE CONJOINT BOARD FOR IRELAND.

THE movement of the Irish Licensing Bodies in the direction of a Conjoint Examination for that division of the country has taken, within the last week, the active shape of a Conference, which has held meetings at the Royal College of Surgeons. The Council of that Body had issued an invitation to each of its colleagues in medical-qualifying, asking them to appoint three delegates to confer upon the subject. The University of Dublin

nominated Drs. Stokes and Apjohn, and Dr. Andrew Searle Hart, a Senior Fellow and Member of the Trinity College Board. The College of Physicians delegated the President, Dr. Hudson, Dr. Beatty and Dr. Little. The Senate of the Queen's University sent Sir Robert Kane, Mr. Ross, and Mr. George Johnston Stoney, F.R.S., their Secretary; and the Apothecaries' Company are represented by their Governor, Dr. Leet, and another of the Directors. The College of Surgeons is itself impersonated by the President, Dr. Wharton; Dr. Maenamara and Dr. Hargreave.

Our readers are already aware that we do not take a very hopeful view of the issue of this Conference. The attempt, however, meets with our most hearty approval, albeit it is at least six months too late. The constitution of the Conference is, moreover, more or less encouraging, inasmuch as in it is contained no representative of the hostile party in the College of Physicians, whose views Sir Dominic Corrigan expounded very plainly in the Medical Council. Saving the obstruction which may be interposed by this party, we believe a feeling in favour of a Conjoint Examination Scheme is strong in all the Licensing Bodies. When the necessity for voluntary legislation was less urgent, when the prospect of "disestablishment and disendowment" was less evident than it is now, the negotiation was upset by financial difficulties, and considerations of dignity. We trust that the present Conference is approaching the subject in a different and more conciliating spirit. Unpleasant as the anticipation may be, it can hardly be doubted that the Conference has to choose between concession and revolution; and while we have as little sympathy with the financial demand of one of the Licensing Corporations, as with the obstructive policy which a party in it have adopted towards the present movement, yet a reasonable compromise would, under the circumstances of the future, evince a wise discretion.

## SCOTLAND.

EDINBURGH.—We regret to record the death of Mr. John Mackenzie, L.R.C.P. and S., Edinburgh, resident physician in the City Fever Hospital, from typhus fever, contracted in the discharge of his duties. Mr. Mackenzie was in the thirtieth year of his age.

ABERDEEN.—Dr. Angus Fraser has been elected physician to the Royal Infirmary, in room of Dr. Harvey.

## Notes on Current Topics.

### Dr. Reed's Cases of Oxygen in Diseases of the Lungs.

THE cases which we have republished from the *New York Med. Journal* seem to have been carefully observed, and as the result of considerable experience in the use of cod liver oil, and oxygen in conjunction are of great value. The increase in weight under the treatment was a marked symptom in almost all the cases. In cases fourteen and sixteen this could not be attributed to the cod liver oil as that disagreed with the patient, and had to be discontinued in consequence. Cases one, two, and three, terminated favourably. In case four, after a decided improvement and increase of weight, an exhaus-

tive diarrhoea set in, and the patient sank rapidly. May not the unfavourable re-action in this case be attributed to a larger dose of oxygen having been given than was desirable. Experience in this country seems to point to this conclusion; a similar effect having not unfrequently been observed in debilitated subjects where too large a dose has been administered. Cases five, six, and seven were very favourable. Cases eight and nine appear to have derived but little benefit.

It is to be observed that no good result seems to have been obtained by increasing the quantity of gas administered in cases where the ordinary dose failed to have any good effect on the diseased condition. Cases ten to thirteen were all favourable, the two latter especially so. Case fifteen unfavourable. Cases fourteen, sixteen, eighteen, nineteen, and twenty, all favourable; while cases seventeen and twenty-one terminated unfavourably. In the last case we again see a diarrhoea setting in after the increase of the dose of gas given.

Out of the whole twenty-one cases reported, fifteen terminated favourably, and in some of them the beneficial effect of the gas was most marked. The other six cases terminated unfavourably. In some of these latter there were complications which partially account for the want of success in their treatment.

### Mortality of Phthisis.

IN a lecture on this subject by M. Constantine Paul, published recently in the *Gazette des Hopitaux*, he said that the disease represents ten per cent. of the whole mortality in France. At Paris the number rises to 13.4 per cent.; at Genoa it is 9.7 per cent.; Naples 8; Rome, 6; Turin, 9; Venice, 8 per cent. To the northward, on the contrary, it increases. In Belgium it is 16 per cent., and in Limburg 21 per cent. In England it appears to be less mortal, the mean mortality being 12 per cent. There is not in England the same difference between town and country as in France. In Germany, the mortality is still greater. From 1839 to 1849, it was at Berlin 17.5 per cent.; at Frankfort, 25.6, at Hamburg, 21.7, at Vienna, 20 per cent. In certain localities in America it reaches 28 per cent.

### Bisulphite of Lime as a Deodorizer.

DR. J. D. TRASK, in the *New York Med. Journal*, calls attention, especially in puerperal diseases, to the bisulphite of lime as a deodorizer. The excess of sulphurous acid, passing into the atmosphere, comes directly in contact with the offensively odorous particles that have escaped, and at once destroys them. In giving vent to collections of decomposing purulent matter, as in the peritoneal or pleural cavity or in chronic abscesses, cloths wet with this preparation, held near the orifice almost entirely prevent the escape into the room of the offensive smell, to the great relief of patient and bystanders. Though the strong solution will destroy fabrics, when properly diluted, as when used for vaginal injections, it neither destroys nor discolors bed-linen.

THE will of Mr. Arthur Kempe, F.R.C.S., of Exeter, whose obituary appeared some few weeks since in this journal, has been proved under £35,000. The deceased had scarcely arrived at middle age.

### Chloral-Hydrate and Bromide of Potassium in Chronic Alcoholism.

DR. F. BRADNACK (*Buffalo Med. and Surg. Journal*) treats chronic alcoholism with unusually large quantities of chloral-hydrate and bromide of potassium together; for a patient suffering from six days' debauch, he ordered: R. Chloral-hydrat., ℥ij.; Potassii bromid., gr. lxxx.; Syrupi simp., ℥j.; Aquæ, f. ℥ijss. M. Ft. haust. These enormous doses, 120 grs. chloral-hydrate, and 80 grs. of bromide of potassium, were given to the patient, merely dividing the mixture into parts, and diluting each with a little water, both doses being taken within five minutes. The effects of this prescription were very gratifying. The patient had a tranquil and unbroken sleep for fourteen hours.

The details of this case appear to him to prove presumptively two points:—1st. That in cases of chronic alcoholism enormous doses of chloral-hydrate are not only tolerated, but are productive of great good; 2nd. That a combination of bromide of potassium with chloral-hydrate furnishes a simultaneous sedative and hypnotic so excellent as to seem to indicate its use in diseases of this nature.

### Medical Use of Alcohol.

WE have received from Dr. Burrows, F.R.S., the able and enlightened President of the Royal College of Physicians of London, a numerous and influentially signed medical declaration respecting alcohol. The importance of the subject at the present time induces us, in spite of the demands on our space, to give publicity to the document as we receive it. There can be no question in the minds of thinking men that it sets forth a phase of the question of the use of stimulants that ought to be carefully weighed by all who may have occasion to prescribe alcohol in any form. The declaration cannot be said to be couched in other than the most moderate terms. It is not unlikely, indeed, that extreme adherents of "temperance" principles will find fault with it, on the ground that it is not forcible enough. We, however, feel that the studied moderation is a commendable feature in the declaration, and we confidently appeal to the large list of signatures of the leaders of professional opinion as a proof that the document really represents an important truth that ought not to be lost sight of. We shall not be surprised if some contention arise, but we think the promoters of this movement have achieved a most laudable success, and may well be content with the response they have met with.

### Bromide of Sodium.

THE prolonged use of bromide of potassium, in epilepsy and other nervous disorders, being often attended with serious inconveniences, Dr. Meredith Clymer believes that in the *bromide of sodium* a substitute has been found that will fully meet every indication for which the bromide of potassium has been given, and is free from the objections which are justly urged against the latter. He remarks in the *Medical World* that the taste of the bromide of sodium, is much less unpleasant than that of the bromide of potassium, being very like common salt, and it may be used to replace the latter, mixed with the food, as with bread and butter, eggs, in milk, &c. Hence it is of more easy administration than bromide of potassium,

to the taste of which some persons have evincible repugnance, and increasing with its use. It is of the first importance that bromide of sodium should be perfectly free of all impurities, particularly of iodine. Larger doses of the hydrated salt are required than of the anhydrous, for it crystallizes with four equivalents of water.

The doses of bromide of sodium are about the same as those of bromide of potassium. In epilepsy he usually gives twenty grains three times daily, and has rarely gone above that amount. It sometimes seems to cause or encourage constipation.

### The Army Medical Department.

STAFF SURGEON FOX has left Dublin to embark for the West Coast of Africa. Staff Surgeon-Major Wall has leave of absence until his retirement on half-pay appears in the *Gazette*. Staff Assistant-Surgeon M. A. Kilroy has rejoined at Chatham from leave of absence. Staff Assistant-Surgeon Charlton is under orders for India. Inspector-General F. W. Innes, M.D., C.B., has been appointed principal medical officer at Netley, vice Inspector-General Beatson, M.D., C.B., who is under orders for India. Deputy Inspector-General J. H. K. Innes, C.B., is on leave of absence, preparatory to embarking for India. Staff Surgeon Hendley has been instructed to assume medical charge of the Portsmouth recruiting district.

### The Value of Circumcision as a Hygienic and Therapeutic Measure.

IN the *New York Medical Journal* there is a very striking article on this subject by M. J. Moses, M.D., who is convinced that the Jews of the enlightened school are inaugurating a dangerous reform, in the desire to invade the hitherto inviolability of the Jewish law; and he would impress upon his professional brethren of other creeds the necessity of explaining to their Jewish patrons the value and *safety* of maintaining circumcision, if not as a religious duty, as a hygienic measure, the importance of which probably influenced its institution as a ceremonial law.

Dr. Moses remarks, that if the following plan is observed, all danger may be considered as provided against, and need *never* occur, if the surgeon watch his case properly.

1st. The amount of tissue sacrificed should be only *just enough* to divide the muco-dermoid junction.

2nd. The reflecting mucous membrane should be carefully adjusted to the cut edge of the dermoid fold.

3rd. The frænum should not be wounded or lacerated.

4th. The wound should be kept open until active bleeding ceases, and the effused lymph has glazed on the line of approximation.

5th. The dressing should be the ordinary coldwater dressing, made of very fine linen, lightly applied.

6th. The surgeon should visit his patient and renew the dressing two hours after the operation.

7th. A careful and attentive nurse, duly warned as to any possible accident, should watch the dressing from minute to minute. The dressing of cold water should be exchanged for one of soft oiled linen the morning following the operation.

8th. As soon as the healing has well begun, all dressing should be discarded, and the parts bathed in tepid water after each voidance of urine.

9th. The operation should be done by a surgeon, and the condition of the child, as to his ability to undergo the ordeal, submitted to his direction.

To guard against hæmorrhage, even under these circumstances, a reliable styptic, tannine, Monsel's iron, pulv. matico, punk, cobweb, the so-called alum-iron, charpie, &c., should be left with those who are charged with the care of the child, with careful directions as to how, and under what circumstances, it is to be applied.

### Consumption of French Wines in England.

MR. SHAW, in a letter to the *Times* of Dec. 13th, says that "during the ten years previous to the reduction of the duties in 1860, the annual average consumption of French wines in this country was about one glass for each person, and it is now one bottle, the increase from 1859 to the end of 1870 being from 695,913 to 4,157,372 gallons, and will this year be nearly a million more. The increase is great, but our population has increased above three millions, and our wealth probably 50 per cent."

### Illness of the Prince of Wales.

NEVER, perhaps has a more sudden wave of sentiment passed over a nation than that produced by the illness of the Prince of Wales. The amendment that has taken place has been the event of the week, and there is something peculiarly gratifying in observing how thoroughly united the nation really is when an occasion like this appeals strongly to its inner feelings. For danger to one life to cause so deep a sensation, not only at home and in our own colonies, but positively throughout the civilized world, is enough to make us feel that that life represents something more to the nation than the pivot of the political machine. Truly, loyalty is not dead, and the British Constitution seems in little danger while so deep and wide-spread affection exists as that which has been exhibited. May the Prince's progress to perfect health be rapid, and may the unparalleled national feeling it has called forth inspire him with determination to be worthy of it!

Still, as we write, we are not unconscious that the dangers that lie in wait for the feeble life are by no means few. We entertain no misgiving as to the watchfulness and care that will still be exercised by his physicians, but we do not forget that in all cases there is a disposition on the part of friends to assume that the moment some crisis is over, all danger is past. This disposition on the part of the public has been very marked. The first favourable indication lead to the immediate conclusion that the Prince was in a fair way of recovery, and much as we hope the most favourable views may prove correct, it is simply absurd to imagine that a few days will suffice to restore the health that has suffered so great an inroad.

Convalescence may be very tedious—it may be interrupted by many sequences of the fever—still, we will hope for the best, though we cannot shut our eyes to the fact that our hopes may not be fully realised.

SMALL-POX is still very prevalent in Dublin. Last week Dr. Robert Mayne, a young physician of great promise, died after five days' illness, of a most malignant attack of the disease, which he contracted in the discharge of his duties, as physician to the Meath Hospital.

### Liniment for Fissure of the Anus.

VAN HOLSBECK has succeeded in curing anal fissures, which had resisted the division of the sphincter, with the following application: dissolve one part of tannic acid in 16 parts of glycerine. A tent wet with this preparation is to be introduced into the rectum night and morning. The bowels to be kept open.—*Medical News*.

### Londesborough Lodge.

IN discussing last week the origin of the illness of the Prince of Wales, we expressed grave doubts as to the conclusions that had been arrived at by our contemporaries, and we published a statement that invalidated them more than could have been expected. We are surprised that those conclusions should have been reiterated without the slightest attempt at re-enforcing the arguments that might somewhat support them, and we acknowledge that we remain as sceptical as ever. In fact, all that has been advanced goes to show how hasty and unjustifiable those conclusions were.

### Dysmenorrhœa.

DR. W. K. BOLING reports (*Nashville Jour. of Medicine and Surgery*), the case of a married woman who had never been pregnant, and who had never suffered in her monthly periods before marriage. A pil. of opium, camphor, and lupulin was prescribed, but the after-effect of the opium being disagreeable, she could not be induced to again resort to opium. She continued to suffer at each period for several months. She then, at the beginning of a pain, sat a few moments on a chamber in which a drachm of spirits of ammonia had been placed. In a minute the pain was gone, and did not return. The same result follows at each period since.

### The Transmission of Virus through the Atmosphere.

M. CHAVEAU has been engaged for a lengthened period on a series of experiments for the purpose of ascertaining the mode of transmission of infecting germs. He collected the virulent matter in a cup which, having placed it on a plate of glass and covered it with a glass bell, he submitted to a temperature of 40° centigrade, cooling the outside of the bell by cotton on which ether was dropped. Having collected the distillate, he inoculated side by side with it, and with the virulent matter from which it arose. The virus of small-pox was the subject of most of his experiments. As a result of these investigations, he has established the fact that the inoculable matter escapes with the distillate, inasmuch as inoculation with it always succeeded. Lastly, he repeated the experiment twice with the virus of epizootic typhus, which more subtly than any other infection, dissipates itself through the atmosphere.

### Gangrene Treated by Turpentine.

DR. LANGE mentions in the *Indiana Journal of Medicine*, a case of gangrene in which turpentine, after other remedies had proved ineffectual, not only saved the patient's life, but also nearly all the parts affected. A girl eleven years old had gangrenous destruction of the right cheek. The part was treated with turpentine oil, and the dressing changed every two hours.

THE mortality of Paris rose last week to 929.

It is reported that the cold was so intense in France last week, that even wine was frozen during transit in a train from Paris to Geneva.

MR COCK has resigned his examinership at the Royal College of Surgeons of England. There will, therefore, be an additional vacancy to fill at the January election.

A COMPETITIVE examination of candidates for appointment as Assistant Surgeons in the Royal Navy will be held in London in the course of February next.

By the will of the late Miss Wood, of Leith, the Leith Hospital, and the Royal Infirmary, become entitled to a legacy of £2,000 each.

The Seamen's Hospital authorities are making urgent appeals to the public for financial help. The expenses of removing from the old "Dreadnought" to their present quarters in Greenwich Hospital amount to nearly £2,000.

THE subject selected for competition for the Hastings Gold Medal offered by the British Medical Association for 1873 is—"On the Pathology and Treatment of Ovarian Diseases," and the award will be made at the Annual Meeting of the Association in that year.

IN the metropolis, last week 1,856 deaths were registered, being 158 above the average. The deaths included 104 from small-pox, and 51 from different forms of fever, of which five are registered as typhus, and 35 as enteric or typhoid, which shows an increase of 16 upon the previous week.

LAST week the total number of paupers in metropolitan workhouses was 34,836, and 86,638 received out-door relief, making a total of 121,474. Compared with the corresponding week in the years 1870, 1869, and 1868, these numbers showed a decrease of 18,495, 25,829, and 20,225 respectively.

WE regret to announce that small-pox is greatly on the increase at Nottingham. There are upwards of 400 patients in the town under treatment for the disease. A sanitary cordon has been drawn round the workhouse, and vaccination and re-vaccination are being carried on to an almost incredible extent.

SIR ALEXANDER ARMSTRONG, K.C.B., M.D., the present Medical Director-General of the Navy, to whom the service is already indebted for several sanitary improvements, has, *The United Service Gazette* understands, submitted to the Admiralty, the desirability of either lemon-juice, pickled cabbage, compressed vegetables, or other anti-scorbutics being issued as a ration to the crews of Her Majesty's ships simultaneously with the issue of salt meat. The present custom of the service is to issue lemon-juice only at such times as the captain may direct on the requisition of the surgeon, but there cannot be a doubt as to the benefit which would accrue to the health of the men by the issue of pickled cabbage or compressed vegetables in conjunction with the salt meat ration.

THE *Philadelphia Reporter* learns that the Rush Medical College was completely destroyed—while the Chicago Medical College and Mercy Hospital were not touched by the fire. The Faculty of the latter institution has offered the former the use of its building and course of lectures, until it is ready to resume its course, and if it should not resume this winter, the free benefit of the course to all students who have paid for their tickets in the Rush Medical College.

It is announced in the *London Gazette* that Sir Alexander Armstrong, M.D., R.C.B., Director-General of the Naval Medical Department, has been placed on the retired list of Inspectors-General of Hospitals and Fleets. This step is in accordance with the terms of the recent Navy Warrant, by force of which any officer who has passed five years without active service is *de facto* retired. It will not involve the removal of Sir Alexander Armstrong from the Directorship of the Naval Medical Department, which is a civil appointment.

AN admirable portrait of Dr. Thomas E. Beatty has been executed to the order of the Medico-Philosophical Club, by T. A. Jones, Esq., President of the Royal Hibernian Academy. The portrait represents Dr. Beatty in his robes as President of the College of Physicians, and having been presented to Mrs. Beatty, has been placed by her in the Hall of the College of Physicians, which it ornaments side by side with the portraits of Sir Dominic Corrigan and Dr. Robert Mayne.

#### MEDICAL DECLARATION RESPECTING ALCOHOL.

As it is believed that the inconsiderate prescription of large quantities of alcoholic liquids by medical men for their patients has given rise, in many instances, to the formation of intemperate habits, the undersigned, while unable to abandon the use of alcohol in the treatment of certain cases of disease, are yet of opinion that no medical practitioner should prescribe it without a sense of grave responsibility. They believe that alcohol, in whatever form, should be prescribed, with as much care as any powerful drug, and that the directions for its use should be so framed as not to be interpreted as a sanction for excess, or necessarily for the continuance of its use when the occasion is past.

They are also of opinion that many people immensely exaggerate the value of alcohol as an article of diet, and since no class of men see so much of its ill effects, and possess such power to restrain its abuse, as members of their own profession, they hold that every medical practitioner is bound to exert his utmost influence to inculcate habits of great moderation in the use of alcoholic liquids.

Being also firmly convinced that the great amount of drinking of alcoholic liquors among the working classes of this country is one of the greatest evils of the day, destroying—more than anything else—the health, happiness, and welfare of those classes, and neutralising, to a large extent, the great industrial prosperity which Providence has placed within the reach of this nation, the undersigned would gladly support any wise legislation which would tend to restrict, within proper limits, the use of

alcoholic beverages, and gradually introduce habits of temperance.

George Burrows, M.D., F.R.S., President of the Royal College of Physicians; Physician Extraordinary to the Queen.

George Bask, F.R.S., President of the Royal College of Surgeons.

G. E. Paget, M.D., D.C.L. Oxon., President of the General Council of Medical Education.

Thomas Watson, Bart., M.D., F.R.S., Physician in Ordinary to the Queen.

Henry Holland, Bart., M.D., F.R.S., Physician in Ordinary to the Queen.

Cæsar H. Hawkins, F.R.S., Sergeant Surgeon to the Queen.

William Fergusson, Bart., F.R.S., Sergeant Surgeon to the Queen.

James Paget, F.R.S., Sergeant Surgeon Extraordinary to the Queen.

Richard Quain, F.R.S., Surgeon Extraordinary to the Queen.

John Hilton, F.R.S., Surgeon Extraordinary to the Queen.

W. White Cooper, F.R.C.S., Surgeon Oculist in Ordinary to the Queen.

Edward H. Sieveking, M.D., Physician in Ordinary to the Prince of Wales.

George D. Pollock, Surgeon in Ordinary to the Prince of Wales.

Thomas King Chambers, M.D., Honorary Physician to the Prince of Wales.

Henry W. Acland, M.D., F.R.S., Regius Professor of Medicine, Oxford; Honorary Physician to the Prince of Wales.

Arthur Farre, M.D., F.R.S., Physician-Accoucheur to H.R.H. the Princess of Wales.

George T. Gream, M.D., Physician-Accoucheur to H.R.H. the Princess of Wales.

Francis Hawkins, M.D., Physician to the Queen's Household.

T. Spencer Wells, F.R.C.S., Surgeon to Her Majesty's Household.

T. G. Logan, M.D., K.C.B., Director-General of the Army Medical Department; Honorary-Physician to the Queen.

Thomas Longmore, C.B., Deputy Inspector-General, Army Medical Staff; Professor of Military Surgery, Army Medical School; Honorary Surgeon to the Queen.

J. Ranald Martin, Knt., C.B., F.R.S., Inspector-General of Hospitals; Physician to the Secretary of State for India in Council.

H. H. Massy, M.D., C.B., Deputy Inspector-General; Head of Sanitary Branch, Army Medical Department.

Thomas Crawford, M.D., Deputy Inspector-General of Hospitals; Head of the Medical Branch, Army Medical Department.

T. Graham Balfour, M.D., F.R.S., Deputy Inspector-General of Hospitals; Head of the Statistical Branch, Army Medical Department.

W. C. Maclean, C.B., M.D., Deputy Inspector-General; Professor of Military Medicine, Army Medical School, Netley.

E. A. Parkes, M.D., F.R.S., Professor of Hygiene, Army Medical School, Netley.

William Aitken, M.D., Professor of Pathology, Army Medical School.

William Johnstone Fyffe, M.D., Surgeon Major; Assistant Professor of Medicine, Army Medical School.

F. De Chaumont, M.D., Staff Surgeon; Assistant-Professor of Medicine, Army Medical School.

C. K. Hardie, M.D., Surgeon Major, Royal Victoria Hospital, Netley.

Henry Thompson, Knt., F.R.C.S., Surgeon Extraordinary to H.M. the King of the Belgians; Surgeon to University College Hospital.

James E. Adams, F.R.C.S., Senior Assistant-Surgeon to the London Hospital.

P. Allen, M.D., Aural Surgeon to St. Mary's Hospital.

James Andrew, M.D., Physician to St. Bartholomew's Hospital.

Henry Arnott, F.R.C.S., Assistant-Surgeon to St. Thomas's Hospital.

C. Bader, Lecturer on Diseases of the Eye, Guy's Hospital.

W. Marrant Baker, F.R.C.S., Assistant-Surgeon to St. Bartholomew's Hospital.

A. W. Barclay, M.D., Physician to St. George's Hospital.

T. A. Barker, M.D., Consulting Physician to St. Thomas's Hospital.

Robert Barnes, M.D., Obstetric Physician to St. Thomas's Hospital.

H. J. Barrett, Surgeon-Dentist, London Hospital.

Richard Barwell, F.R.C.S., Assistant-Surgeon and Lecturer on Anatomy, Charing-Cross Hospital.

W. R. Basham, M.D., Senior Physician to the Westminster Hospital.

H. Charlton Bastian, M.D., F.R.S., Physician to University College Hospital.

Edward Bellamy, F.R.C.S., A.K.C., Senior Assistant-Surgeon, Charing-Cross Hospital.

James Risdon Bennett, M.D., Consulting Physician to St. Thomas's Hospital.

Frederick Bird, M.D., Obstetric Physician to the Westminster Hospital.

P. Black, M.D., Physician to St. Bartholomew's Hospital.

G. Fielding Blandford, M.D., Lecturer on Psychological Medicine, St. George's Hospital School.

John S. Bristowe, M.D., Physician to St. Thomas's Hospital.

W. H. Broadbent, M.D., Physician to St. Mary's Hospital and to the London Fever Hospital.

B. E. Brodhurst, F.R.C.S., Surgeon, Orthop. Department, Guy's Hospital.

Charles Brooke, M.A., F.R.S., Consulting Surgeon of the Westminster Hospital.

Thomas Bryant, F.R.C.S., Surgeon to Guy's Hospital.

William B. Carpenter, LL.D., M.D., F.R.S., Registrar of the University of London.

Samuel Cartwright, F.R.C.S., Professor of Dental Surgery, King's College.

W. B. Cheadle, M.D., F.R.C.P., Assistant-Physician to St. Mary's Hospital.

W. S. Church, M.D., Assistant-Physician to St. Bartholomew's Hospital.

F. le Gros Clark, F.R.C.S., Surgeon and Lecturer on Surgery, St. Thomas's Hospital.

Edward Cock, Consulting Surgeon to Guy's Hospital.

Alfred Coleman, F.R.C.S., Dental Surgeon to St. Bartholomew's Hospital.

Holmes Coote, F.R.C.S., Senior Surgeon to St. Bartholomew's Hospital.

John Couper, M.D., Surgeon to the London Hospital.

George Cowell, F.R.C.S., Senior Assistant-Surgeon to the Westminster Hospital.

John Croft, F.R.C.S., Surgeon to St. Thomas's Hospital.

T. B. Curling, F.R.S., Consulting Surgeon to the London Hospital.

Edward Cutler, Consulting Surgeon to St. George's and Lock Hospitals.

Herbert Davies, M.D., Senior Physician to the London Hospital.

J. Hall Davies, M.D., Physician-Accoucheur to Middlesex Hospital.

Walter Dickson, M.D., R.N., Medical Inspector of Her Majesty's Customs.

Thomas B. Diplock, M.D., Coroner for West Middlesex.

Langdon Down, M.D., Physician to the London Hospital.

Robert Druitt, M.R.C.P., Lond., F.R.C.S., President Metropolitan Association of Officers of Health.

Dyce Duckworth, M.D., Assistant-Physician to St. Bartholomew's Hospital.

C. Hilton Fagge, M.D., Assistant-Physician to Guy's Hospital.

William Farre, M.D., F.R.S., President of the Statistical Society.

George T. Fincham, M.D., Physician to Westminster Hospital.

J. Cooper Forster, F.R.C.S., M.B., Surgeon to Guy's Hospital.

Tilbury Fox, M.D., Physician to Skin Department University College Hospital.

Henry W. Fuller, M.D., Senior Physician to St. George's Hospital.

George G. Gascoven, F.R.C.S., Assistant-Surgeon and Lecturer on Anatomy, St. Mary's Hospital.

G. Duncan Gibb, Bart, LL.D., Assistant-Physician to the Westminster Hospital.

S. J. Goodfellow, M.D., Senior Physician, Middlesex Hospital.

T. Henry Green, M.D., Senior Physician to Charing-Cross Hospital.

Robert Greenhalgh, M.D., Physician-Accoucheur to St. Bartholomew's Hospital.

## Literature.

## THE SCIENCE AND PRACTICE OF SURGERY.\*

THIS is a magnificently edited work, and must have cost its author immense labour and considerable expense. We trust that he will be repaid for both of these by a wide perusal of the volume before us. In his preface, Mr. Gant observes truly, that it is now many years since a new systematic work representing the science and practice of surgery, has appeared in this country. The work is descriptive, not theoretical. The whole is arranged under three heads. First.—Structural condition, with its signs or symptoms, and diagnosis. Second.—Causes and effects of the morbid condition. Third.—Course, termination, consequences, and prognosis. The surgical anatomy of some special parts is occasionally introduced, such as those implicated in hernia and in the ligature of vessels. Fourth.—Treatment is fully considered. The various kinds of surgical instruments are noticed and fully described.

The Introduction gives a preliminary view of the nature of surgery as a science and as an art; the latter chiefly regarding operations, anæsthetics, &c. Next follows the recognised division of pathology and surgery into two parts, general and special, the latter being divided into "injuries of and diseases of textures," and "injury and diseases of organs and regions." In the first part are treated of inflammation, tumours, degenerations, ulceration and mortification, scrofula, rheumatism, syphilis, erysipelas, pyæmia, glanders, tetanus, &c. In the second part the author speaks of wounds, diseases of bones, aneurism, deformities, excisions, and amputations. There are also chapters on diseases of the eye, ear and teeth, and other special branches of regional surgery. The last part of the work will make it well adapted as a surgical text-book for students, as it contains chapters on amputations, on stricture, and other operations commonly met with in hospital practice. The author refers to the elaborate treatise in the "System of Surgery," edited by Mr. Holmes, as having been most useful to him in editing this work, as also to his indebtedness to the recent works of Erichsen, Druitt, and Pirrie. He has embodied his Lettsomian lectures on "Excisional Surgery," as delivered before the Medical Society of London in 1871, in the work. There is an index to this work. The 470 wood engravings are, many of them, original and drawn by Mr. C. D'Alton. But the large proportion of the engravings have been made from the wood blocks of Messrs. Churchill, which have illustrated the works of Sir A. Cooper, of Liston, and Fergusson. His friends Mr. John Wood and Mr. William Adams have kindly given illustrations of the operation for which they are celebrated, and Heather Bigg has given the wood blocks from his manual on "Orthopraxy." There is a very important little chapter at the end of the works for students preparing for examination at the College of Surgeons of England, viz., "A Guide to the Examination for the Diplomas of Member and Fellows."

With regard to the author's views on various points which have recently attracted the attention of the profession, we find him saying in page 16 of the Introduction with regard to the administration of chloroform, "simplicity with efficiency is always a great recommendation, and thus the administration of chloroform by means of a piece of lint or a handkerchief can be accomplished at once. Even in hospitals inhalers are not commonly employed. I have seen chloroform administered in some thousands of cases without an inhaler, during upwards of twenty years, both in hospitals and private practice, without a single death, or even an approach to a fatal termination, when the requisite precaution for safety has

been observed." Bichloride of methylene has been administered, it seems, in six or seven thousand cases with only one death. Local anæsthesia is eligible in all superficial and limited operations such as puncturing abscesses, avulsion of the toe-nail, and excision of small tumours.

In the matter of syphilis, the author leans to the side of what is called the *unicists*, and thinks that "while the indurated chancre possesses the greater power of producing constitutional syphilis, yet that soft chancre may also occasionally pass this causatus relation." With regard to treatment, he observes that mercury has been, and still is credited with the most potent prophylactic influence. If mercury be not preventive of systemic infection, no other known medicinal agent possesses such influence in any perceptible degree. Blue pill, in doses of three to four grains twice or thrice a day, is praised as well as the iodide of mercury by Mr. Gant, whose experience in the treatment of syphilis must have been very extensive at the Royal Free Hospital, one of the venereal hospitals of London. In pustular eruptions, orchitis and periostitis, iodide of potassium is, he thinks, more remedial than mercury. He has prescribed it in some thousands of cases with advantage at the Royal Free Hospital.

Pyæmia, says Mr. Gant, is scarcely amenable to any treatment. Stimulants and tonics, with free ventilation, are recommended in such cases. Tetanus has no remedies worth much at present. Chloroform is useful, and may assuage the pain. Some foreign observers have recently had good results from very large doses of opium in tetanus.

Mr. Gant speaks with merited praise of the practice of occlusion of arteries by means of torsion, which has been specially investigated by Mr. Cooper Foster. At the seat of torsion, the two inner coats of the artery are torn across, and reduplicated up the vessel, perhaps in the form of a complete funicular sheath, one-fifth of an inch in length, and at the upper or smaller opening of this opening or funnel, a conical blood-dot forms, occupying the base and extending up the vessel. The twisted condition of the artery, itself usually a persistent change, and the reduplicated sheath of the two inner coats, above, acting as a valve, are quite sufficient provision against the recurrence of hæmorrhage at the time of operation, and subsequently different modes of torsion are practised. The artery may be drawn out for about half an inch by one pair of common serrated forceps, and its attachment seized by another pair of serrated forceps. The free portion is then twisted off by about a dozen turns of the former instrument, or the end of the vessel may be simply twisted several times, without detaching it, as recommended by Velpeau and Fricke. "This is the method," says Mr. Gant, "I ordinarily practise, scarcely ever employing ligature to any artery, of whatever size; it has been much practised also by my colleague, Mr. J. D. Hill, and it is, I believe, generally preferred."

In the treatment of aneurism, Mr. Gant observes that galvano-puncture is of comparatively recent date (1832). It is justifiable only, he thinks, or chiefly in cases of internal aneurism, or aneurism at the root of the neck; in fact, where compression, ligature, or any other method have failed or are impracticable. As to the cause of mollities ossium, the author says that it is unknown. The disease in no way arises from an imperfect formation of the osseous texture, and does not usually occur before the middle period of life, or subsequently; thus, also, differing from rickets. No known medicinal remedies have any curative agency. The chapters on fractures and dislocations are very full, and contain all that is known upon these matters. There are plenty of plates here to assist the student who is rather rusty in his anatomy. Chapter xxiv., "On Diseases of Joints," is full of useful remarks. Mr. Gant remarks that inflammation of the synovial membrane ensues occasionally from gonorrhœa, such sinovitis has been incorrectly named "gonorrhœal rheumatism," but "gonorrhœal sinovitis" would be a

\* "The Science and Practice of Surgery," illustrated by four hundred and seventy wood engravings. By Frederick S. Gant, F.R.C.S. London: Churchill, 1871, Pp. 1,266.

more accurate designation. Serum, rather than lymph, is effused into the joint, and the disease terminates without disorganisation in a few weeks. Or, it proceeds sometimes to ulceration of the cartilages, and continues for months or a year or two. In such cases, the joint may become ankylosed. In Chapter xxxvi., there is a very interesting account of deformities, whether acquired or congenital. Spasmodic contraction of the sterno-mastoid muscle is the most common cause of wry-neck. Tenotomy (Stromeyer, 1831) is the best treatment. Paralytic wry-neck may be treated by galvanism. Strabismus (operation introduced, 1840) is now treated by *sub-conjunctival* division of tendons, commonly the rectus. Club-hand arises either from spasmodic or paralytic conditions of muscles, and is to be remedied by tenotomy in some cases, aided by instrumental manipulation.

Simple contraction of the knee-joint may occur from some affection of the ham-string muscles. Division of the tendons may be required, and then the limb gradually extended. In talipes varus, the gastrocnemius, libialis anticus, and posticus muscles are chiefly implicated. These tendons should be divided, and Scarpa's shoe used. In flat foot, the peroneal tendons may often require to be divided, and those of the extensor communis digitorum, after which the foot may be placed in a Scarpa's shoe. In t. calcaneus, the tendons of the t. anticus, extensor pollicis, and longus digitorum may be divided.

In Chapter xxxvii., there is an interesting account of the excision of various joints, a subject to which the author has devoted a considerable share of attention and interest. Excision of the knee-joint is carefully described, and the same is done with regard to the elbow-joint. Diseases of the wrist-joint fit for excision are spoken of, and the circumstances which admit of excision of the tarsal bones considered. The chapters "On Amputation" are full and satisfactory. The chapter "On Injuries to the Scalp, Cranium, &c." is full, and there is a good *resumé* of the surgery of the eye, which occupies about fifty pages. There is, also, a chapter "On the Nose and its Diseases," although in this part there is but little novelty. Diseases of the cheeks and lips are then treated of, and hare-lip and epithelial cancer are well described. The latter disease occurs almost solely in men who are smokers according to our author, from the irritation caused by the pipe. Excision of the tongue is described. There are some excellent woodcuts of tumours of the jaw. Diseases of the larynx, trachea, and œsophagus, are well done, and the operative procedures well described. Then come disease of the spine and lateral curvature, and there are some capital plates of the supports required in treating such cases. The chapter "On Hernia" is well done, and there are some really excellent plates showing how trusses should be worn.

The chapter "On Hernia" is up to the knowledge of the hour, and the various illustrations of trusses will doubtless be of use to the general practitioner. Mr. John Ward's difficult, but satisfactory operation for the radical cure of hernia is well described, and there are several plates given, which show the knives and other instruments employed for the operation.

In his chapter "On Stricture," Mr. Gant says that experience has shown that not only may the male urethra be treated safely by Holt's immediate method; but that a light stricture, undilatable gradually beyond a certain degree, and any further distension of which would cause severe constitutional disturbance, may be forcibly dilated or ruptured up to the natural size of the urethra, and without producing any dangerous symptoms. The results of this procedure on Mr. Holt's hands have been eminently successful; and the experience of other surgeons has generally confirmed its value. Mr. Gant has not seen much constitutional disturbance follow the operation of splitting the urethra; but in one case, operated on in another hospital, extravasation of urine ensued, for which we treated the patient at the Royal Free Hospital, and he recovered. Many deaths have, however, ensued. Mr. Teevan says fifteen which have not been recorded.

In taking leave of Mr. Gant's handsome work, we have pleasure in saying that it is well worthy of the careful perusal of all students of the art of surgery. It is likely, we believe, to be much used as a text-book for students and persons preparing for examinations at the colleges, and we hope the author may reap the benefit of the vast literary labour which it must have entailed in the renown and more solid acquisitions which it may bring him.

#### PULMONARY CONSUMPTION.\*

WE have here an immense mass of well recorded experience, ably condensed into a moderate sized volume, and put into such form, as to be highly interesting to the reader, while it cannot but afford, even to experienced hands, a considerable amount of much that is of high practical value. The term "Phthioplasm" wasting or decaying formative material, is given by Dr. Williams, to that degenerating form of "bioplasm" or "germinal matter," which, deposited in the lung locally as the result of inflammation, or generally through the adenoid tissue of the lung in the form of miliary tubercle, causes its degeneration and destruction, so producing the disease known as pulmonary consumption.

It is interesting to read (p. 22) how the question, propounded by Dr. Williams more than forty years ago, as to what elementary part of the lung is affected to produce the constant shape and form presented by miliary tubercles, has now been pretty well answered by the researches of Drs. Sanderson and Wilson Fox. Miliary tubercles are modifications of the adenoid tissue. This view seems to Dr. Williams more correct than the notion of Virchow, that tubercle, as well as pus and all other new formations, has its origin in the cells of the connective tissue only.

Allowing this, Dr. Williams does not however admit that adenoid tissue is essential to the production of phthit sical consolidation from what has been called yellow tubercle, either in its crude or caseous stage.

Chronic consolidations of lung leading to caseation and softening, are admirably and concisely explained, and treated in Chapter X. Here we leave the suppurative element of consumption, which has occupied our attention in the preceding chapters, and come to consider those forms of consumptive disease of lung where the sarcophytes multiply and become concrete; if with much fibroid elements tending to contract and wither, if with but little fibroid, tending to caseation and excavation of the lung.

Justice is done to the researches of the late Dr. Addison, of Guy's, who was one of the first to show that grey induration of the lung was of inflammatory nature and origin, and not, as Lænnec believed, a degree or stage of tuberculosis of the organ.

In Chapter XV, we have family predisposition and certain other causes of consumption, traced out by Dr. Theodore Williams. The fact that tuberculous animals, as well as tuberculous human beings, are prone to beget tuberculous offspring seems well proved; and further, the author draws attention to the tendency that asthmatic parents have to produce phthit sical children. That such is the case our own observations prove, but it is, as Dr. T. Williams remarks, a fact hardly sufficiently recognised. Tables of statistics, which must have cost much patient toil, decidedly bring out the fact, that family predisposition hurries the onset of phthit sical. The disease sets in at an earlier age in those who are of phthit sical ancestry, than among those who are not. Dr. T. Williams seems to have been the first in this country to draw attention to this important fact, and his observations accord with

\* "Pulmonary Consumption: Its Nature, Varieties, and Treatment, with an Analysis of One Thousand Cases to Exemplify its Duration," by C. J. B. Williams, M.D., F.R.S., Senior Consulting Physician to the Hospital for Consumption at Brompton, and Charles Theodore Williams, M.A., M.D., Oxon., Fellow of the Royal College of Physicians, and Physician to the Hospital for Consumption at Brompton. Pp. 402. London: Longmans, 1871.

those made on a more limited scale, by M. Briquet. It is satisfactory to find from the cases given in this chapter, that the strongest hereditary taint does not hinder the beneficial effect of remedies if persevered with.

The duration of phthisis without reference to sex, seems but slightly influenced by family predisposition, but though the duration of the disease is not notably curtailed, yet statistics show that family predisposition has considerable influence in shortening the duration of life, such limitation amounting in males to more than six years, and in females to not quite five years. We must here remember, however, that those who come of a consumptive stock, are liable to be attacked earlier than others whose families are free from taint.

Passing over the notes of cases illustrating the various forms of pulmonary consumption and the chapter on the duration of the disease, which is an abstract of Dr. T. Williams's paper, read before the Royal Medico-Chirurgical Society, and published in Vol. LIV. of the *Transactions*, we come to the chapters on treatment.

Looking back on an experience of forty years in the treatment of consumption, it is in the ten years from 1840 to 1850, that a marked improvement was noticed in the effects of treatment. The reason appears to be, that the antiphlogistic began to give way to the tonic method. A mixture of dilute nitric acid with iodide of potassium and sarsaparilla, was for a time in great favour with Dr. Williams, till something better appeared. It seems to us that the above mixture would produce whatever good might be done by free iodine, for we know that the combination of iodide of potassium with ordinary nitrous ether, always turns brown, in consequence of the liberation of the iodine by the small amount of acid always present in *sp. etheris nitrosi*, and of course nitric acid would, by combining with the potassium, liberate the iodine freely in a mixture which contained iodide of potassium.

Cod liver oil stands well with Dr. Williams, he has used it much, and apparently with great satisfaction and success, and the reader will do well to attend to the hints given, as to the way in which to give the oil, and the way to prepare a delicate stomach for its reception.

Few, now-a-days, are likely to dispute the virtues of cod liver oil in phthisis, though some will think more of it than others, to us it has always seemed that the younger the patient, the more is the benefit likely to be derived from the administration of cod liver oil.

The hypophosphites so much lauded by Dr. Churchill, of Paris, have in the hands of Dr. Williams, proved decidedly beneficial in certain cases. How they act (says Dr. Williams), is uncertain, for Churchill's theory does not get the credit with Dr. Williams, that his practice does. A mixture of the hypophosphite with phosphoric acid, is a good deal used by Dr. Williams, and here it is presumed that the hypophosphorous acid is set free, and is the active ingredient.

A perusal of the cases recorded tend to show that this combination is a serviceable one.

Passing over the very valuable chapters on palliative, dietetic, and hygienic treatment of consumption, we come to the last chapter in the book, written like those immediately preceding it, by Dr. Theodore Williams.

This chapter is on climate, a subject to which the author has paid considerable attention. Just at present the climatic treatment, like many other points in connection with pulmonary phthisis, is unsettled, and therefore often unsatisfactory.

Places have been written up by interested parties in the most extravagant way, as being perfect in their climatic advantages; if the invalid wants bracing, he can have a bracing air, or if he wants soothing let him but move a few yards, and he obtains an air deliciously soothing to his irritable lungs; moreover, while warm in winter, the probability is that we are assured the place described is beautifully cool during the hottest summer. This is the way in which we often hear some special place spoken of,

when perhaps all that can with truth be said, may be that certainly the climate is a very elastic one, as far as its virtues are concerned.

In the chapter before us, however, there are none of the above faults to be found. Phthisis, the author tells us, occurs both in hot and cold climates, but the disease is not precisely the same in each case. The true tubercular phthisis running a rapid course is most prevalent in hot climates, at least so says Dr. Guilbert, and he has we know observed carefully in the matter. The phthisis of the colder climates is more an inflammatory disease tending to contraction and caseation of the lungs, and to run a chronic course.

These facts show what danger may accrue from moving a phthisical patient into a very warm climate; there being reason to think we may make him tuberculous and so hasten his end. Practically every one must know by this time, that in advanced consumption, the patient's death is very often materially accelerated by removal to a hot and relaxing climate.

Without going into lengthy descriptions of individual places, Dr. T. Williams gives us valuable hints as to the way in which climates are to be used. When much irritability of vascular system is present, then a soft marine climate is good. Where consumption originates in septic influences, a pure and dry climate should be tried at a good elevation, as up in the Alps or the Andes. These high bracing climates are presumed to have a vivifying influence on the bioplasm, and on all the vital functions.

This short chapter concludes with a few words on the folly and cruelty of sending hopeless cases of phthisis to die in a foreign land. We feel how impossible it is in a notice like the present, to draw attention to all the matters of interest contained in this book; we have no hesitation in saying that the work is one that may be said to mark well the present state of our knowledge both as to the nature, causation, varieties, and curability, of consumption. It certainly is a book on which Dr. Williams may look with some satisfaction after his forty years of work, and certainly he need not fear being placed among those great physicians, who at the close of an active life of practice, have had the uncomfortable reflection forced upon them in their retirement, as to whether they had done most of harm or of good by their physic.

## Foreign Medical Literature.

### HISTORY OF THE DOCTRINE OF CONSTITUTIONAL SYPHILIS.

By DR. FERRARI, of Bologna.

(Translated with notes by C. R. DRYSDALE, M.D.)  
From *Lo Sperimentale*, t. XXVIII.

ABOUT the first half of the 16th Century, physicians commenced to confound venereal and syphilitic diseases. Thus G. Vella (1508), and Antonio Brassavola (1551), the latter in a work on the "French Disease," referred all venereal diseases to the same origin, so that, until the days of Hunter, the whole doctrine of venereal diseases fell into the greatest confusion. It was from this epoch that we may say that the doctrine of unicity of venereal sores and gonorrhoea may be traced, and it was upheld by Swediaur, Vacca, Barbantini, and John Hunter, as it is in our day by Sperino, Ligneau, Lane, Gascoyen, and others. One author (Devergie, Senior) remarked that no better proof of unicity exists than the fact observed by him, that three men all had connection with the same woman, and that one contracted urethritis, the other an ulcer, and the third a different lesion. Swediaur relates that he treated three women for syphilitic ulceration of the tonsils after a gonorrhoea, of which they got rapidly well

—thanks to mercury; and Baumés relates how that five persons became affected with syphilitic eruptions after gonorrhœa.

Experiments, indeed, seemed to have confirmed some in this way of thinking, since Hunter having inoculated himself on the penis with gonorrhœal pus, saw arise two ulcers, followed later on by symptoms of constitutional syphilis. However, the experiments of Balfour, Tode, Bell, Bosquillon, Hernandez, and of the school of the *Midi* of Paris, were opposed to these views, by which it is now clearly proved that even the urethra may, in any part, be the seat of ulcerations, which are, in such cases, the origin of syphilitic infection. And to Ricord, it is that we owe the discovery of the hidden chancre in 1838. The idea of an urethral ulcer, indeed, is very ancient, since Celsus believed that gonorrhœa was derived from an ulcer of the urethra; and as Mayerne asserted during the last century. There can be no doubt, then, that gonorrhœa may be virulent when ulcers exist in the urethra.

Unicists, however, observe that hidden urethral chancres are most rare compared to the numbers of cases of syphilis appearing after gonorrhœa; in fact, of 380 inoculations made by Lafont Gouzy with pus from gonorrhœa, there was only twice any ulcer seen to follow; whilst Ricord, out of 4,692 cases of syphilitic eruptions, verified the existence of a previous ulcer in 4,011 cases, and, in 681 cases, an ulcer and a gonorrhœa together had preceded the eruptions. Ricord thinks that the hidden urethral chancre only occurs in one of a thousand cases of gonorrhœa. And in clinical experience, we know very well, how very rare it is to see syphilitic eruptions succeed to gonorrhœa alone. The identicists, however, say that Martins, out of sixty cases of syphilitic skin disease, noticed that gonorrhœa had preceded it forty-six times; and that Cazenave had noticed the same in eighteen cases out of sixty-two. But to this it is replied that such reasonings are erroneous, because the first of these authors had merely drawn his information from the words of the patients themselves; and Cazenave had taken for syphilitic eruptions, in many cases, the eruptions caused by the use of balsamic remedies. Thus, we may conclude that there is no nosological identity between gonorrhœa and ulcers for three reasons: 1. That pathological anatomy and experiment have proved now-a-days in a manner which admits of no doubt, the existence of the hidden chancre; 2. That in conjunction with the rarity of hidden chancres, is the rarity of syphilitic disease after gonorrhœa; 3. That these gonorrhœas have been recognised to be symptomatic of hidden ulcers by means of inoculation.

*Unity and Duality.*—Gonorrhœa being thus considered as an entirely local disease, the power of causing infection resides now, according to the mass of syphilographers, in the two forms of venereal ulcers; and thus arose the doctrine of unicity in 1838, which did not last long, however; for, in 1851, Bassereau proclaimed to the world the doctrine of the duality of syphilitic sores, one being entirely local, the other, according to the author, a proper virus. He proved his theory partly from history, asserting that, whilst in the ancient authors ulcers are mentioned, there was no mention of any special dyscrasia like syphilis in their writings, whereas, when syphilis at first appeared, Torella, Vigo, Botallus, and Fallopius said that the ulcer which preceded this disease, was very unlike that described in the writings of the ancients. These facts, which were thus demonstrated *à priori* by Bassereau, have been confirmed since then by many other observations, besides these of their author, by Clerc, Diday, Rollet, and Fournier, by all of whom the just nosological distinction between these ulcers has been shown. These differences have been thus expressed:—1. That whilst the one sore is usually solitary and rather unfrequent, the other is generally multiple and much more frequent. 2. The first is painless, the second generally painful. 3. Whilst the one sore secretes very little, is usually superficial, and with a process of adhesive inflammation, healing *without* a scar, the other has an abundant secretion, is excavated, with sharply cut edges, with its floor covered

with abundant granular exudation, and heals *with* a scar. 4. The one is generally indurated at its base, the other most frequently is soft, or has only the induration of inflammation. 5. The one is not inoculable on the same individual, says Bassereau, does not become diffused, and very rarely, indeed, becomes phagedænic, or gangrenous; the other is auto-inoculable on the patient, and is easily inoculated on the neighbouring parts, as also frequently complicated by phagedæna and gangrene. 6. The first has an incubation of twenty-five to thirty days, the second has no incubation. In the one, there are many of the inguinal glands enlarged, but these are indolent, and scarcely ever suppurate; in the other there is no necessary induration of the glands, but whenever there exists a mono-glandular bubo, it easily suppurates and becomes an ulcer. 8. The first kind of ulcer is only seen in the human race, the other is transmissible to animals.

These distinctions were derived from the following data. With regard to the frequency of the ulcers, it was observed at the Hôpital du Midi that, of 254 patients with "soft sores," 116 had from 3 to 6 sores; 41 patients had from 6 to 10 ulcers; and 8 patients had from 10 to 15 ulcers. Again, of 456 cases of "hard sore" noted by Fournier, 226 patients had only one ulcer, and 115 had more; but scarcely any had more than two or three. Clerc, of Paris, out of 267 patients, found in 224 cases, only one hard sore. And with respect to frequency, among the class of patients seen at the Hôpital du Midi, of 341 cases of chancre, 126 were "hard sores," and 215 "soft sores." Puche, indeed, made out that, of 10,000 sores seen at the Midi, only 1,955 were followed by secondary symptoms.

The induration of the ulcer is noticed beneath it, and there is a difference between this and the inflammatory swelling seen around soft sores, especially when induration is well-marked, when it is cartilaginous. Induration arises without any inflammatory symptoms, whilst the soft sore has notable swelling, redness, and other marks of inflammation. According to Robin, the induration consists of cellular tissue, with some cutaneous elastic fibres mingled with it; and Virchow affirms that the hard ulcer presents the same development as gummy tumours; and that there is a proliferation of the cellular tissue, in which the elements live for a time; finishing by softening, degeneration, and ulceration. "Path. des Tumeurs," Paris, 1869.

The induration of the infecting sore is a sign of greatest importance in the differential diagnosis of the two forms of venereal ulcerations. One of the most distinguished of modern writers on this subject, Dr. Bumstead, of New York, says that this induration is the only symptom we ought to look for in the two species of primary ulcers. The unicists, however, categorically deny the existence of this specific character of the infecting sore, because they have found it wanting in the female, in the majority of cases. For instance, they say that Melchior Robert, in four cases, found only once a distinctly indurated sore. Pironi, of 157 ulcers in women, only noticed one which was truly indurated; and H. Lee, of seventy-one infecting ulcers, noticed only nineteen which were hard. Dr. Ferrari, of Pisa, remarks that, in his wards for venereal cases, he has pretty often found this character absent, especially in the fourchette, or the vagina; but this he has rather ascribed to the special nature of the tissues concerned, than to induration being really absent. In fact, Virchow has demonstrated that in these organs, where there is a want of connective tissue, the cells and nuclei of the "sifiloma" would appear to be formed by the proliferation of the nuclei of the capillaries.

It may very well be, that this exception in the case of women is due to the fact, that the proliferation of the anatomical elements of the "sifiloma" takes place only at the expense of the nuclei of the capillaries, and hence it is very natural that hardness should be but little, or not at all appreciable to the touch; because the neoplasm is but little evident, on account of the small proliferation of these elements. Besides, according to Bumstead and

Pellizari, it is most marked in the balano-preputial sulcus and on the lip. The unicists, also say that the ulcer which becomes hard is no longer an ulcer; but a true manifestation of syphilitic infection. But in opposition to this idea of theirs, is the fact of confrontation, used by Bassereau, Clerc, Diday, Rodet, Fournier, and Caby. According to Signund, of Vienna, in seventy-one cases, the induration appeared on the 9th day; in eighty-four cases, on the 10th; and in twelve cases on the 19th day. Specific induration ordinarily remains for some time after the ulcer has been cicatrised, and, according to the statistical results of Puche, its presence is rarer after the third month, and very rare indeed after the eighth month, although the said writer has observed in eleven cases that the induration was perceptible from 390 up to 2,662 days after contagion, and he gives one when it remained nine years. Bumstead has likewise observed some specific indurations, which have lasted two or three years; and Ricord saw an induration in one case remain for thirty years. Babington also observes that induration may appear before the ulcer, but this is a doubtful opinion of his, according to some Mr. Berkeley Hill thinks so too. Clinical observation has shown clearly that, in the infecting ulcer there exists a period of incubation between the moment of contagion and the appearance of the ulcer, whilst in the other the appearance of the ulcer takes place in a few hours, or in two or three days at most. Diday, out of twenty-nine cases of infecting ulcers, had a mean of fourteen days of incubation; Chevalier in ninety cases, found the incubation 15-18 days; Clerc found it to be thirty days in different cases; and Castelnau found it to be thirty days in one case, whilst Bumstead found it to be ten days in some cases. The unicists, however, deny the existence of the incubation; and point to the observations of Fournier, Poncet, and Diday, which showed the incubation period *sometimes* to be about five days. They also speak of the observations of Langlebert, Ricord, Bassereau, Milsens, Robert, Zeleschi, and Davasse, from which it would seem that, even in twenty-four hours after inoculation, the infecting ulcer showed itself. But to these reasons of the unicists, we may first of all remark, that the number of cases cited is so small as to constitute rather an exception than a rule, and in the second place that the incubation was shown to be always pretty long, in cases when artificial inoculation was employed, just the cases when experiments might be made more accurately and precisely. Thus Delhomme inoculated from a true syphilitic ulcer in one case in 1850, and there was an incubation of 180 days. Rinecker, in 1852, found an incubation of twenty-five days. Baerensprung inoculated in 1859, and there was an incubation of thirty-three days. Danielssen, in 1853, saw a similar incubation of fourteen days. Rollet, in 1856, saw the incubation last eighteen days. Gibert, in 1859, saw syphilis when inoculated incubate nineteen days. Cullerier, in 1861, inoculated and saw an incubation of fifteen days. Feini, in 1861, saw a case of twenty-one days' incubation. Waller saw a case of thirty-four days' incubation in 1851, after inoculating with the *blood* of a syphilitic patient; and Gibert, in 1859, on a similar incubation which lasted thirty-five days. Pellizari, in 1860, made three inoculations with blood, and in one there was an incubation period of twenty-two days. Again, when the secretion of mucous tubercles was inoculated, Wallace, in 1835, made three inoculations, and the times of incubation were from twenty-three to thirty-six days. Gibert, in 1859, made two inoculations from mucous plates, and saw a period of incubation of eighteen and twenty-five days. Waller saw one which lasted twenty-five days; Guyenat, in 1859, one which lasted twenty-four days; Baerensprung, in 1859, one of thirty days; Lindwarn, in 1860, saw one which lasted twenty-six days; Galligo, in 1860, one which lasted seventeen days; Hebra, in 1861, inoculated with secretion from mucous tubercles, and the incubation period was sixteen days.

The secretion of pustular syphilitic eruptions was in-

oculated by Wallace in 1862 in two cases, and there was an incubation of twenty-nine days. Vidal found, in one such case, an incubation of twenty-eight days; and Rinecker, in 1852, also inoculated from a congenital pustular syphilitic affection, and found the incubation period to be twenty-eight days.

(To be continued.)

## Correspondence.

### MECHANICAL MEANS OF CURING CERTAIN DANGEROUS DISEASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The fact that our body consists of mechanical as well as vital properties is too much forgotten; and it has for long been considered by me, that we neglect too much the former powers, particularly when the system is deranged by disease. In fever, when the circulation is deranged by its increased rapidity, and by the congestion of particular organs: can this state be remedied so that the congestion may be relieved, and the feverish state diminished by restoring a more equable circulation; and do we possess mechanical means so as to diminish the extent of the circulation, and thus increase the power of the heart in cases of great exhaustion from loss of blood, &c.? The answer: these conditions can certainly be relieved.

Firstly, or secondly, by diminishing the extent of the circulation by stopping the arterial blood proceeding to one or more of the limbs, the quantity sent to the heart is increased and more vigour given to its action, by which the congestion in particular organs is removed. When the congestion of the lungs takes place in the course of fevers, a great difficulty of breathing occurs, and dangerous spasms are the consequence; might not this state be relieved by encircling the arms and legs near the trunk with a ligature? The blood continues to be sent to the limbs, but the ligature prevents its return by the veins, and an accumulation of blood takes place there, which relieves the breathing. The removal of the obstruction may be made at any time, but requires to be done with care.

THOS. A. WISE, M.D., F.R.S.

Norwood, December 12th, 1871.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR,

SIR,—You may perhaps think the following cases worthy of a place in your columns:—

May 28, 1871, I was called in to see W. E., a fine, plethoric young man, twenty-two years of age; found him labouring under violent headache, skin very hot, urgent thirst; pulse 130; tongue slightly furred, high-coloured urine; severe pain of loins, and pain all over; face suffused; nausea and vomiting, and pain of epigastrium. Has been ill about twenty-four hours; bowels pretty regular.

R Ol. Croc. tig. grs. iv.;  
Mucil. acac.;  
Secch. alb. āā. ʒij., M.

et Adde aq., font., ā ʒiv., sigae, one tablespoonful every fifteen minutes: until the bowels are opened.

Emp. lytt. nuoh.;  
Emp. lytt. epigast.;

R Nit. potass;  
Sp. æther nit.;  
Tinct. hyosey. utriusque, ʒij.

Aq. font., āā ʒvi.; coch. ij., amp. 2nds horas.

20th.—The oil operated in twelve minutes copiously, with four more evacuations during the night. The blisters rose well; headache gone; pulse 100. Very much better in every way; much less thirst.

Repeat the saline mixture.

30th.—Has no complaint except weakness.

Miss C. E., twenty-three years of age, a fine, stout, healthy young lady, was attacked about the same time with symptoms precisely similar. This was pronounced at once to be typhus fever, and was treated accordingly. It went through the regular stages of synochus, synocha, and ended in great debility. She was given up as hopeless. Petechia had appeared;

the extremities were cold; pulse imperceptible at the wrist. In this state, at midnight, bottles with warm water were applied, and a wine-glassful of pure whiskey was given. In a few minutes the pulse rose; the whiskey was repeated and repeated until the pulse rose full, and general heat restored. She finally recovered, and is now as hearty a lady as there is in England.

Query—Would not my mode of treatment have saved all she suffered?

Your obedient servant,

Clun, Salop, ALEX. LANE, M.D., R.N.  
Dec. 8, 1871.

P.S.—I should have added that in both cases; there had been severe rigors.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—When forwarding you a simple statement (omitting details) of what I considered a rare and most interesting case of twin birth, and which appeared in your impression of the 15th ult., I little dreamt it would call forth, for the edification of your numerous readers, the learned critique which appears in your issue of the 22nd inst., from the pen of Francis M. Luther, M.D., of Cappelquin. In the first place, I pass over as altogether unworthy of notice the unwarrantable liberty he takes in his opening sentence with the Doctor; in the second place, there are so many ifs in this literary and scientific gem that I cannot spare time to take them up in order, one by one, and will, just for brevity's sake, sum them all up under one head in the words of the old and familiar *avlage*, namely,—“If the sky should fall we would all catch larks.” Had the case been his—luckily (not “lucky,” please) for the patient it was not—no doubt he would “have completed the delivery in a few minutes, without any aid from Nature.” Extinguish, Nature, your ruschlight before this luminary! He would “have ruptured the second bag of water,” if he could have found it; after doing so, he would deliver, by the forceps, the head, “were it near enough;” or, “very easily,” run—not insinuate; no, no, that would be too slow—his hand within the uterus, along the body of the child—seize a foot—turn—bring down the foot—and behold, the delivery is completed! The marvellous rapidity with which all this is accomplished almost takes one's breath away; but this is the age of steam and railroads.

The last if but one, and I have done,—“If your correspondent's first suspicion (rightly suspected are my words) as to the existence of twin pregnancy, was shaken (but it wasn't) by the non-appearance of labour pains, after two hours' delay and exhibition of ergot, it was his bounden duty to remove the placenta.” Sir, had I attempted, under the circumstances, to remove the placenta, which was firmly attached and unyielding, and the funis unshrivelled, which was evident by repeated examinations, made both night and day all the time, as the patient resided not fifty perches from my own door—I say, had I attempted to remove the placenta before the second child was born—setting aside altogether the probability of its being united, which it almost always is in twin cases—I should inevitably, have brought on a fatal hemorrhage, for the simple reason that there could have been no contraction while the second child remained in utero.

The last if, I venture to say, is of more importance than all the rest put together, namely,—that the dispensing doctors (in certain quarters), too seldom avail themselves of the services of so last a man.

Thank Providence he was neither my consultant nor assistant in this case—a private one—or, instead of having to record three living, it would have been, one saved by Nature's efforts, and two—mother and second child—dead through unskillful art.

I am, Sir, truly yours,

R. G. SHEER, M.D.

Killyleagh, Nov. 25, 1871.

P.S.—From the birth of the first child until the birth of the second (three days) there was not the slightest constitutional disturbance, nor the loss of so much blood as scarcely to stain a folder.

R. G. S.

## Medical News.

The College of Surgeons of England.—At a meeting of the Council on the 14th inst., the reports of the Examiners

in Dental Surgery, and of a committee appointed to inquire into charges made against Mr. Washington Evans, a Member of the College, were received and adopted. Mr. Charles Hawkins brought forward a motion for placing the successful candidates for the Fellowship in classes, but after discussion the motion was not adopted. Mr. Gay called attention to the large proportion of rejected candidates at the preliminary examinations, and after a discussion of his notice of motion for inquiry into its causes, it was agreed, on a proposition by Mr. Simon, that the subject should be referred to a committee that had been already appointed to investigate the subject of the preliminary examinations. Mr. Erichsen moved that vacancies in the offices of professor and lecturer to the College be advertised before the elections.

Royal College of Physicians of London.—At an extraordinary meeting of the College yesterday, the 18th inst., W. John Francis Murphy, of Queen's College, Cork, passed his primary professional examination; and the following gentlemen having conformed to the Bye-laws and Regulations and passed the required examinations, were granted Licences to practice Physic, including therein the practice of Medicine, Surgery and Midwifery.

Francis James Baily, M.R.C.S., 51 Grove st., Liverpool.  
Thomas Hughes Brabant, M.R.C.S., North Audley street, W.  
William Ward Carr, M.B., Lond., Lee grove, Blackheath.  
Frank Coomber, M.R.C.S., 51A Trinity square, London.  
Arthur Evelyn Davies, M.R.C.S., Newport, Monmouthshire.  
Robert Eardly-Wilmot, M.R.C.S., King's College Hospital.  
George Cooper Franklin, M.R.C.S., Victoria Park Hospital, N.E.

John Fraser, M.D. Toronto, Strabane, Ontario, Canada.  
James Elliot Graham, M.D., Toronto, Canada.  
John Lamond Hemming, M.R.C.S., 10 Southwick place, Hyde Park.

William Hamerton Jalland, M.R.C.S., Guy's Hospital.  
George Thomas Langridge, M.R.C.S., 7 Myddleton square, E.C.

Frederick Arnold Lees, M.R.C.S., Meanwood, near Leeds,  
Walter Augustus Parker, M.R.C.S., 55 Cathcart road, Brompton.

Howell Rees, M.R.C.S. Ystalyfera, Swansea.  
Edward Roger Rowland, M.R.C.S., 1 St. Georges place, S.W.

Henry Ryley, L.R.C.P., Edin., Fulbourn, Cambridge.  
Edward Sergeant, M.R.C.S., St. Thomas's Hospital.  
William James Todd, M.R.C.S., 4 Gloucester road, N.W.  
Edward George Younger, M.R.C.S., Holly Mount, Blackheath, S.E.

Douglas William Duke, who passed his examination in medicine, July 1871, and has obtained a recognised qualification in surgery.

Royal College of Surgeons of England.—The following Members, having passed the required examinations for the Fellowship on the 22nd, 23rd, and 24th ult., were, at a meeting of the Council held on the 14th inst., duly admitted Fellows of the College:—Henry Trentham Butlin, L.R.C.P. Lond., Camborn, Cornwall, diploma of Membership dated Nov. 1867; Junius Hardwicke, L.K.Q.C.P. Irel., Rotherham, Yorks, June, 1844; Charles Higgens, L.R.C.P. Lond., L.S.A., Hambledon, Hants, April, 1868; Chas. James Oldham, L.R.C.P. Lond., Norfolk sq, Brighton, Jan. 1870; Herbert William Page, M.B. Cantab., Carlisle, Nov. 1869; Samuel Bowen Partridge, L.S.A., Bengal Medical Service, Aug. 1851; Richard Rendle, L.S.A., Forest hill, April, 1868; William Sanderson Wyman, M.D. St. And., L.S.A., Upper Richmond road, Putney, April, 1862. Four other candidates were examined, but failed to satisfy the Court of Examiners, and were referred for a period of twelve months' further professional study.

Apothecaries' Hall, London.—At a Court of Examiners, held on the 14th instant, the following gentleman received the L.S.A. Diploma, viz.:—Messrs. John Routledge Bosworth, of Sutton, Surrey; Francis Dorrell Grayson, of Henley-on-Thames; John Delprat Harris, of Exeter; Frederick Fraser Hopkins, of Henley-in-Arden; Edward Milner, of Birmingham; William Arthur Mosely, of Nassau, Bahamas; Isaac Pitt, of Birmingham; and the following passed the primary professional examination, viz.:—Messrs. Alfred Ernest Cave, of the London Hospital; George John Eady, of King's College; William John Gard, of Guy's Hospital;

Alfred Vavasour Griffiths, of Queen's College, Birmingham; Francis James Jopnes, of King's College; William Edmund Parker, of Queen's College, Birmingham; and Henry Birt Vincent, of St. Bartholomew's Hospital.

University of Dublin.—The following degrees have been conferred:—*Bachelor of Medicine*.—Jacob Robertson Headlam O'Connor, John Godfrey Rogers, David Kennedy, Thomas Drapes, Patrick John Molony, Thomas Blair Worthington, William Mark Whittaker, Richard Henry Quill, Henry John Tweedy, Maurice Blunden, Thomas Hamilton Moorehead, James Armstrong, Henry Comyn, Andr. Francis Dobson, Richard White, George Gibson, Thomas W. Browne, Christopher Elliott, Otway Peter Browne, John Waugh. *Master in Surgery*.—Patrick John Molony, John Godfrey Rogers, Jas. Armstrong, Richard Henry Quill, Thomas Blair Worthington, Edward Mazier Courtenay, Francis Geo. Mayberry, John Waugh, Otway Peter Browne, Henry Comyn.

Those who have authority in Scarborough, and are interested in its well being, should take into immediate consideration its sanitary condition. Mr. G. P. Dale, F.R.C.S., who has been endeavouring to remove a stigma from Londesborough Lodge, has thrown a lime-light into the ordinary lodging houses of Scarborough; and a pretty state of things his statement points to. The matter should be officially inquired into, and the evils thoroughly combated, if the people of Scarborough wish their gay place to remain in favour. In striking confirmation of the impression thus conveyed, Mr. William Cadman writes:—"Three times I have called the attention of the Scarborough authorities to their manure dépôt. The sad and much-to-be-lamented result of the Prince of Wales's visit will, yes, must,—rouse them. Scarborough (I believe I may say) is seldom, if ever, free from fever. Now, all the filth, ashes, &c., from the town, which must contain the poison generated by sewage, is carted through the town, and deposited about half a mile, or a little more, in the valley above Lord Londesborough's Lodge. The wind is mostly down or up this valley. When down, the poison must pass into and about Londesborough Lodge. The Convalescent Hospital is also very near this depot, and the immediate neighbourhood is seldom, if ever, free from fever. Any one having to drive to Seamer must pass this depot. The Londesborough party had to do so, and must have felt the sickening effect. Also a dreadful smell ascends from the drain along the sands past the Grand Hotel. This effluvia with an easterly wind, must ascend to Londesborough Lodge; the westerly wind bringing the poison from the depot." Mr. Dale and the professional gentlemen acting with him, who say, apparently with much satisfaction, that the fall of the drains in Londesborough Lodge to the main sewer "is very great," show that the arrangement is eminently qualified to discharge the sewer gases into the house; in fact, if the drains are not ventilated externally,—and we do not hear that this is the case,—that result at times cannot be avoided. No one for an instant thinks of attaching the slightest blame to Lord Londesborough, or to insinuate that his house is any worse than scores of others. It is of the utmost importance that the truth should be arrived at.—*Builder*.

## OBITUARY.

### DEATH OF DR. MAYNE, OF DUBLIN.

THE profession in the Irish metropolis has been much shocked by the untimely death of Dr. Robert Mayne, Surgeon to the Meath Hospital, which occurred on Saturday morning last. Dr. Mayne was the son of the late much esteemed Dr. Robert Mayne, of Gloucester street, and on the death of Dr. Strong, about a year and a half since, he was selected to succeed to the Surgeony to the Meath Hospital. The talent which he had evinced in that capacity, and his youth, strength, and energy, gave great hopes as to his future career,—hopes which have been unhappily blasted by his melancholy death. In the beginning of last week he was struck with small-pox, which speedily showed a most virulent hæmorrhagic tendency, to control which all efforts were vain; and the attack ended, as we have said, in his death, on last Saturday.

## IRISH POOR-LAW VACANCIES.

Kilbrush Union, Cragaknock Dispensary District.—Salary, £100; vaccination and registration fees, £8 1s.; annual number of dispensary tickets, 611; annual number of visiting tickets, 215; average of district, 37'310; population of district, 9,689; date of election, 1st January.

Lismore Union, Lismore Dispensary District.—Salary, £100; vaccination and registration fees £9 2s.; annual number of dispensary tickets, 1,691; annual number of visiting tickets, 302; average of district, 26'021; population of district, 6,240; date of election, 2nd January.

Thomastown Union, Knocktopher Dispensary District.—Salary, £95; vaccination and registration fees, £5 4s. 3d.; annual number of dispensary tickets, 494; annual number of visiting tickets, 171; average of district, 28'357; population of district, 5,448; date of election, 11th January.

## NOTICES TO CORRESPONDENTS.

### NOTICE TO OUR READERS.

IN consequence of Christmas Day falling on Monday,—the day on which we usually go to press—and the day following being kept as a General Holiday, Subscribers will not receive the Journal until Twenty-four hours later than usual. The same Number will also contain the Half-yearly Index.

IN deference to the wishes of several correspondents, the MEDICAL PRESS AND CIRCULAR will, in future, be printed upon TONED PAPER.

M. A. B.—Thanks.

Dr. W.—We shall be glad to receive further cases, in illustration of the treatment you mention. Your extensive experience in India entitles your opinion to great weight, and the present time is most opportune.

Dr. D. P.—The letter has been forwarded to the correspondent named.

STUDENT.—You will find full particulars in our last Students' number.

A. G. L.—Dr. Letheby. "On Food," is announced as shortly to be published by Messrs. Baillière, Tindall, and Cox.

Mr. F. R. H.—We decline to insert your advertisement in our columns. It is a form of quackery we strongly object to.

G. W.—1. Yes; 2. By Mr. Bellamy, of the Charing-cross Hospital.

Dr. DE PASCALE, Nice.—Your letter and enclosure received, and shall be attended to. We regret to hear of the accident.

## VACANCIES.

Stockwell Fever Hospital. Resident Medical Superintendent. Salary £400 per annum, with residence. (See advt.)

North Wales County Lunatic Asylum. Assistant Medical Officer. Salary to commence at £80, with board and residence.

King's College, London. Professorship of Forensic Medicine.

Wandsworth Board of Works. Medical Officer of Health. Salary £50.

St. Marylebone, Middlesex. District Medical Officer. Salary £20.

Sunderland Infirmary. Junior House-Surgeon. Salary £60.

Liverpool Dispensaries. Assistant House-Surgeon. Salary £108.

Manchester Royal Infirmary. Junior House-Surgeon. Salary 80 guineas.

Newark Hospital. Resident Medical Officer. Salary £100.

Thomastown Union, Stoneyford. Medical Officer. Salary £95.

(See advt.)

## MEETINGS OF THE LONDON SOCIETIES.

WEDNESDAY, Dec. 20th.—SOCIETY OF AILTS, 8 P.M. "The Study of Botany." By James Collins, Esq.

Friday, Dec. 22nd.—QUECKETT MICROSCOPICAL CLUB, 8 P.M.

## OPERATION DAYS AT THE LONDON HOSPITALS.

WEDNESDAY, Dec. 20.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.  
ROYAL FREE HOSPITAL.—Operations, 2 P.M.

#### APPOINTMENTS.

BENTLEY, A. J. M., M.B., C.M., Resident Physician to the University Clinical Wards of the Royal Infirmary, Edinburgh.  
BISHOP, J., Resident Physician to the Royal Infirmary, Edinburgh.  
BRAITHWAITE, J., M.D., Assistant-Surgeon to the Leeds Hospital.  
CARTER, A. H., M.B., Physician's Assistant, and Pathologist to the South Staffordshire General Hospital, Wolverhampton.  
DE MERIC, H. E., Junior House-Surgeon to the Royal Free Hospital.  
DOBSON, N. C., F.R.C.S., Surgeon to the General Hospital, Bristol.  
GLYNN, T. R., M.B., Physician to the Liverpool Royal Infirmary.  
LINDSAY, J. M., M.D., Physician-Superintendent to the Derbyshire Lunatic Asylum, Mickleover.  
M'CORMACK, M. J., M.B., Medical Officer of Health for Lambeth.  
MARSHALL, H., M.D., Consulting Surgeon to the General Hospital, Bristol.  
SLATER, J. S., House-Physician to St. Thomas's Hospital.  
TAYLOR, D. T., M.B., Resident Medical Officer to the Small-pox, Fever, and Lock Wards of the Royal Infirmary, Edinburgh.  
VOSE, J. R. W., M.D., Consulting Physician to the Liverpool Royal Infirmary.  
ARMY MEDICAL DEPARTMENT.—Staff Surgeon W. T. Paliologus, from half-pay, to be Staff Surgeon, vice T. S. Barry, deceased.  
Assistant Surgeon J. F. Beattie, M.D., from 79th Foot, to be Staff Assistant Surgeon, vice H. Nugent, placed upon half-pay.

#### Marriages.

HIGGS—LOWTHER.—On the 11th inst., at Harston, Leicestershire, Frederick S. Higgs, M.B., Surgeon, of Heighington, Lincoln, to Lucy Lowther.

#### Deaths.

COWDELL.—On the 15th inst., at Dorchester, Charles Cowdell, Esq., M.D., physician to the Dorset County Hospital, aged 56 years.  
RAINES.—On the 13th inst., suddenly, at Clarence House, Hull, Charles Raines, M.R.C.S.E., aged 21.  
WILLIAMS.—On the 8th inst., at Sudbury, Suffolk, Caroline Anne, the wife of John Williams, M.D., aged 31.

#### THOMASTOWN UNION.

##### KNOCKTOPHER DISPENSARY DISTRICT.

**MEDICAL OFFICER WANTED.**—The COMMITTEE of the above District will, at their Meeting to be held at Stoneyford on THURSDAY, the 11th day of JANUARY, 1872, at the hour of Eleven o'clock, A.M., proceed to Elect a Medical Officer, having the proper qualifications (in the room of Dr. THOMAS BRADLEY, who resigned), at a Salary of Ninety-five Pounds per annum, exclusive of Registration and Vaccination Fees.

Personal attendance of Candidates will be required.  
Applications, enclosing Testimonials and Qualifications, will be received up to Half-past Ten o'clock, A.M., on the abovenamed day, by JOHN BRADLEY, Hon. Sec.  
Inisnag, Stoneyford, December 12, 1871.

#### UNIVERSITY OF LONDON.

The following are the Dates at which the several EXAMINATIONS in the UNIVERSITY OF LONDON for the year 1872 will COMMENCE:—

MATRICULATION.—Monday, January 8, and Monday, June 24.  
BACHELOR OF ARTS.—First B.A., Monday, July 15.  
Second B.A., Monday, October 28.  
MASTER OF ARTS.—Branch I., Monday, June 3; Branch II., Monday, June, 10;  
Branch III., Monday, June 17.  
DOCTOR OF LITERATURE.—First D.Lit., Monday, June 3  
Second D.Lit., Tuesday, October 8.  
SCRIPTURAL EXAMINATIONS.—Tuesday, November 26.  
BACHELOR OF SCIENCE.—First B.Sc., Monday, July, 15.  
Second B.Sc., Monday, October 28.  
DOCTOR OF SCIENCE.—Within the first twenty-one days of June.  
BACHELOR OF LAWS.—First LL.B. } Tuesday, January 9.  
Second LL.B. }  
DOCTOR OF LAWS.—Thursday, January 18.  
BACHELOR OF MEDICINE.—Preliminary Scientific, Monday, July 15.  
First M.B., Monday, July 29.  
Second M.B., Monday, November 4.  
BACHELOR OF SURGERY.—Tuesday, November 26.  
MASTER IN SURGERY.—Monday, November 25.  
DOCTOR OF MEDICINE.—Monday, November 25.  
EXAMINATION FOR WOMEN.—Monday, May 6.  
The Regulations relating to the above Examinations and Degrees may be obtained on application to "The Registrar of the University of London, Burlington Gardens, London, W."

WILLIAM B. CARPENTER, M.D.,  
Registrar.

December 8, 1871.

#### MALVERN COLLEGE.

The NEXT TERM will commence on Thursday, 15th January.

**TO APOTHECARIES.**—An Established House in Dublin is open to treat with a party as Junior Partner; capital, £500. Apply to R. SMITH, Esq., 17 Eustace street, Dublin.

**QUEEN'S COUNTY.—TO MEDICAL MEN.**—Desirable Investment for a General Medical Practitioner. Auction on FRIDAY, the 22nd day of December. To be sold by PUBLIC AUCTION, at the Court House, Maryborough, at the hour of Eleven o'clock, A.M., on the above-named day, if not previously disposed of by private sale, the following property:—That very large and commodious dwelling-house, with stabling, out-offices, and garden, situate in the best part of the main street of the town of Maryborough, which is the Assize Town of the Queen's County, where the late Thomas Pilsworth resided, and successfully carried on for forty years the business of an apothecary and druggist. The shop is well fitted with the fixtures usually found in a respectable medical establishment, and the purchaser can have them at a reasonable valuation. This is a desirable investment for an apothecary and general medical practitioner. The premises are held under a lease for an unexpired term of seventeen years, from the 25th March last, at the abated rent of £20 per annum. From the situation and extent of the premises they are admirably suited for a hotel or other public business.

HENRY ODLUM, Auctioneer, Monntmellick.

For further particulars apply to John Roe, Solicitor, 27 Up. Sackville street, Dublin, and Rockview, Maryborough, by whom proposals for private sale will be received up to the 23th inst.

#### TO MEDICAL PRACTITIONERS AND APOTHECARIES.

##### IN BANKRUPTCY.

IN THE MATTER OF JOHN JOSEPH CLORAN, OF MAIN ST., LOUGHREA, IN THE COUNTY OF GALWAY, APOTHECARY AND DRUGGIST, A BANKRUPT.

**THE GOODWILL AND INTEREST in the Business and Premises known as the MEDICAL HALL, LOUGHREA, in the county Galway, with the STOCK-IN-TRADE therein, will shortly be offered for Sale, and an opportunity thus afforded to Medical Men of purchasing a first-class Business, with one of the best connections in the West of Ireland attached.**

The Business has not been suspended, but is being actually carried on. Full particulars will appear in future advertisements, and in the meantime persons requiring information are referred to

MR. WILLIAM WEBB, Manager of the Apothecaries' Hall of Ireland, Mary st., Dublin; or to

Messrs. OLDHAM and EATON, Solicitors, 42 Fleet st., Dublin.

**STOCKWELL FEVER HOSPITAL.**—The Managers of the Metropolitan Asylum District require the services of a RESIDENT MEDICAL SUPERINTENDENT for the above Hospital. The appointment will be made upon a probation of three months, and the salary is £400 per annum, with an unfurnished residence (detached from the Hospital building), and coals and gas.

Applicants must possess a Medical and Surgical qualification as required by the Regulations of the Local Government Board, and produce satisfactory testimonials of their qualifications for the appointment.

Forms, on which only applications will be received, may be obtained at the Offices, No. 37 Norfolk street, Strand, where the applications, accompanied by testimonials, are to be delivered by or before the 1st January, 1872.

By order,

W. F. JENN, Clerk to the Board.

37 Norfolk street, W.C., 6th December, 1871.

#### NAVAL MEDICAL DEPARTMENT,

ADMIRALTY, SOMERSET HOUSE, December, 1871.

A Competitive Examination of Candidates for appointment as Assistant Surgeons in the Royal Navy will be held in London in the course of February next, of which further particulars, as to date, &c., will be duly announced.

Candidates having the necessary qualifications to practise Medicine and Surgery, under the Medical Act, and who are not above twenty-eight years of age, are eligible to attend.

Application for admission to this Examination should be made in writing, without delay, to the Director-General of the Medical Department of the Navy, Admiralty, Somerset House.

A. ARMSTRONG,

Director-General.

#### COKESTOWN HOUSE, INSTITUTED FOR

#### THE MEDICAL TREATMENT OF THE INSANE OF BOTH SEXES.

This highly respectable Mansion in no respect resembles, either internally or externally, what is usually known as an Asylum.

The Demesne, Conservatories, Graperies, and Grounds are unusually extensive, and in good condition.

There are Billiard Tables for both sexes, with indoor and outdoor amusements, including Vehicles.

Cokestown House is within three miles of Carrick-on-Suir Station, with a like distance from Fiddow, both on the Waterford and Limerick Lines, and in connection with the G. S. & W. and Kilkenny Lines.

For terms, and Form of Admission, apply to the Resident Physician, JOHN PEPPARD, M.D., &c.

Cokestown House, Pittown, co. Kilkenny.

#### CADBURY'S COCOA ESSENCE

† Absolutely genuine, economical, being about three times the strength of the Homœopathic Cocos and French Chocolates ordinarily sold; suitable for the weakest stomach, owing to two-thirds of the Fatty Matter, which forms 50 per cent. of the Nib, being removed. "The richness is thus overcome in a manner far preferable to the impoverishment of the Cocoa by dilution or Adulteration."—*The Lancet*. "Cocoa treated thus will, we expect, prove to be one of the most nutritious, digestible, and restorative of drinks."—*British Medical Journal*.

WITH TITLE PAGE AND INDEX.

## INAUGURAL ADDRESS

READ BEFORE THE SURGICAL SOCIETY OF IRELAND,

By JAMES WHARTON, M.D., F.R.C.S.,

President of the Royal College of Surgeons in Ireland.

MR. VICE-PRESIDENT AND GENTLEMEN,—I am called upon by virtue of the exalted office to which I have been chosen, as President of this college, to occupy the chair upon this occasion. I shall not engage your attention beyond a very brief period, barely sufficient indeed, for the purpose of inaugurating *pro forma*, the coming session of the Surgical Society of Ireland.

This society, as you are doubtless aware, has, like the college which has fostered it, been established for the cultivation, and consequently, the promotion and development of surgery.

In the prosecution of this duty its labours have not been in vain, but on the contrary, have tended directly to place upon a safe, and therefore, a practical basis, some of the most important of its resources; and to establish the pathology of certain lesions and affections previously unrecognised, or, at the best, not clearly understood.

Permit me to enumerate some instances in proof of these statements. So long as thirty years ago, Robert Williams, contributed a paper on the treatment of bursal tumours, by means of subcutaneous incision of their sacs. At the same period Robert Smith, exhibited specimens of chronic rheumatic arthritis of the articulation of the lower jaw; and somewhat later, the same surgeon, a specimen of impacted fracture of the anatomical neck of the humerus, which he described as unique. Operation for hare lip, so early as the fourth day after birth, successfully performed by Dr. Dawson, of Dungannon. Contributions by John Houston and Robert Adams, on strangulated congenital hernia, occurring in the one case at the 26th, in the other, at the 42nd year of the patient's age. Excision of the head of the humerus, by Dr. Badely, in 1842. A year later, the treatment of vascular tumours of the rectum with nitric acid, by John Houston; and of aneurism by compression, by Dr. O'Bryen Belling-

ham, with the treatment of which formidable disease his name is so honourably identified. The pathological condition of an artery after compression for the cure of aneurism as shown by J. W. Cusack.

The exhibition of various instruments and appliances, at different periods, for specific purposes, as for ligature of deep-seated arteries; for pushing back the eperon in operations for artificial anus, and for dividing the stricture in strangulated hernia, by Leonard Trant. For facilitating the reduction of dislocation of the humerus, by Dr. Gray, of Galway; and of dislocation generally, for compression of arteries, for hernia, and for removal of the lower jaw by Francis P. Strange. For examination of cavities with external openings, and of the urethra, whereby stricture situate as far as the bulb, may be exposed to view by means of reflected light as in the endoscopes of the present day, by Dr. Massy. It were an easy task to prolong this list, but I must resume.

In the use of the term surgery I do not intend to restrict it to its original acceptation, which dates from a very remote antiquity, many centuries antecedent to the Christian era, but to view it according to its true significance, as a component part of medicine (thus differing from Hippocrates), embracing and embodying all subjects, which reflect light upon the art and science, the diagnosis and prognosis, as well as the treatment of those ills which come under the daily observation of the practising surgeon.

Thus regarded the society over which I have the high honour of presiding, should afford opportunities for its comprehensive and philosophic study, and most assuredly it complies with this requisite condition.

If we glance at the curriculum, to use a school phrase, we shall find it includes topics for consideration and discussion, which, apart from their intrinsic merit, are of special interest when brought to bear upon the practice of a profession, which is, as I believe, of all secular vocations, the most noble, because the most philanthropic and useful that can employ the time, stimulate the industry, and consecrate the talents of those who have adopted it.

A list of the subjects that may be brought under

notice on the occasion of the society's meetings will be found on the back of the title-page of its bye-laws, from a review of which it will be manifest that as there is a large field to select from, so is there no branch of science connected or affiliated with medicine which may not, in this room, be introduced, even in the absence of the author of a communication, and with or without discussion should he so desire. This arrangement is admirably suited to the case of those who residing, it may be in the country, find themselves unable to be present or take part in the usual proceedings. I would it were more frequently taken advantage of by our brethren at a distance, so that the results of their experience might be recorded for our own and our successors' good.

The wide scope the society thus offers, places it in a peculiarly prominent position, because it invites its members, at home or abroad, according to their respective pursuits and acquirements, to engage its attention, while they present their views or experience, even upon themes for which special societies have been founded and supported. This it effects not in any spirit of antagonism or rivalry, but in the bond of brotherhood and good-will, regarding and recognising their members as fellow workers and fellow labourers, seeking with them to advance the best interest of medicine, and to raise it to that standard of excellence whereby its true position may "be known and read by all men," and its practice conducted with clearness and precision, to the confusion of all organised empiricisms.

Gentlemen, although this and kindred societies have done much and good work, yet much remains to be done. Medicine is progressive and must be so regarded. From its very nature it cannot be allowed a stationary existence, it must either recede or make way. Hybernation, if I may so express myself, is not suited to its constitution. It must be true to its engagements, or, tacitly it may be, confess its inability to fulfil its lofty mission. I do not mean, as an agent, merely to combat disease, or to oppose its progress, but as a means and an effectual means, of which there is abundant proof, of promoting christianity and civilisation, with their attendant and consequent blessings. Of these, it is not my province in this place and at this time to speak, but rather, of the provision afforded by this society for the promulgation of sound opinions upon questions of professional and of public interest. For instance, how incomplete, and therefore unsatisfactory is the local and constitutional treatment of cancer; and how deserving of further investigation. One of my predecessors indeed, in this chair, Richard Carmichael, applied his vigorous intellect to this subject; and more recently, Maurice Henry Collis, cut off, alas, in the prime of manhood; yet the management of this dire affection has not yet received that amount of attention it so eminently deserves. And here, in passing, I may be permitted to remark that tannic acid, liberally used as a daily dressing in open cancer, is an application of great efficacy. I do not hesitate to recommend it with some degree of confidence, and to promise that it will not, at all events, be wholly disappointing. This acid, I feel persuaded, is possessed of some quality independently of its astringency, so that I regard it as well worthy of exhibition in several forms of cachexia, by virtue of some inherent property, whereby it promotes assimilation. For this latter opinion, I feel sure there is an authority, though I am unable to name or refer to it at present. In the same manner, the attention of the society could, with great benefit, be directed to the most approved method of arresting hæmorrhage from divided arteries, particularly with reference to torsion and its applicability to the main artery of a limb. This practice has been had recourse to, extensively I believe, in one of the Metropolitan hospitals, Dr. Steevens', and perhaps in others. So, may I allude to the section of the neck of the femur, as recommended by Mr. Adams, and Dr. Sayer, of New York, for the purpose of remedying the deformity arising from bony ankylosis of the hip-joint. To the latter

named, this college and society owe a deep debt of gratitude for the presentation of his work upon this subject, and of the model illustrative of the effect of his operation, as derived from *post-mortem* examination. The treatment of croup, as regards the admissibility of tracheotomy, advocated by so high a name as that of Trousseau, would be well worthy of a communication, not only, as it were for its own sake, but because the doctrine itself is so diametrically opposed to the teaching and practice of one of the most distinguished of my predecessors, William Henry Porter, and indeed, so far as I can judge, to the generally received opinion of the Dublin school.

The foregoing are a very few of the examples to which many might be added, as suggestive of the benefits which may be accomplished by the instrumentality of this society, I shall allude to one only, and which, as it affects the common weal, justly holds a place in the society's programme. I refer to Hygiene, than which no question can be of greater importance, or more deserving of the earnest consideration of those who would strive to ameliorate the condition of their fellows, and to advance the cause of social progress. This college, mindful of the important trusts committed to it by Royal Charter, has not failed to show its interest in sanitary science, by appointing Professor Cameron to deliver a course of public lectures on this subject, year by year. By this means, as well as by the course recently taken by the University of Dublin, which now issues a diploma in state medicine, it may be hoped that by the joint efforts of these two educational bodies, the cause of hygiene will come to be regarded in its proper light, as entitled to hold a dignified position in the curriculum of all licensing authorities. I am, indeed, to some extent at all events, aware of the magnitude and the difficulties of so important a subject, but this consideration, so far from presenting an obstacle to the elucidation of its principles in this room, should have an effect of an opposite kind, because amongst the members of this society will be found able supporters of its laws, and strenuous advocates in favour of their diffusion. Gentlemen, I must be true to my promise, not to occupy your time, and therefore hasten to bring these remarks to a close, in remembrance that the business of the evening is yet to be transacted. I have to thank you very heartily for the patience with which I have been listened to, and to express a hope that on this and every other evening in which it may be our privilege to meet and confer together, I shall not be wanting in my duty towards you; that the session now about to commence, may not be inferior to any that has preceded it, and that as hitherto, its transactions shall be conducted with calmness and good faith, worthy of its past history and traditions worthy of the common object it has in view, and worthy too, of the members of this learned, long established, and distinguished society.

#### THE RADICAL CURE OF HERNIA.\*

By JOLLIFFE TUFNELL, Esq., M.R.I.A., F.R.C.S.,  
Surgeon to the City of Dublin Hospital.

THE following case is one illustrative of the efficiency of Syme's modification of Watson's (or rather Gerdy's) operation for the radical cure of reducible hernia, and the cast upon the table gives the appearance of the parts, two months after its performance.

The patient was a man, thirty-seven years of age, of small stature, and particularly nervous and excitable temperament, but of very sober habits. He had had laxity of the abdominal rings from childhood, with tendency to rupture on both sides, but in February 1859, whilst running against a head wind to give notice of a fire and exerting himself violently, the hernia came down at the left side. Subsequently, he had an attack of bron-

\* Read before the Surgical Society of Ireland.

chitis, and this was followed by winter cough, which, annually returning, had the effect of confirming the protrusion, and at last of rendering the hernia totally irreducible. He had worn a truss at first, but it only partially acted, the intestine being down, as a general rule, with the truss pressing on the bowel.

Early in 1869 he came under my care. He was then suffering from a large scrotal entero-epitocoele at the left side which was perfectly irreducible, he had also incipient hernia upon the right side. The action of the bowels was much interfered with; he was continually suffering from dragging pains in the abdomen, and unfitted for the performance of his duty as an inside servant. By placing him in bed, and keeping him on a very low diet for nine weeks, the omentum became so far absorbed that the hernia could be returned; but no truss that he procured prevented the intestine (for any length of time) from protruding. He tried several of the ordinary forms, as well as the scrotal or block truss, the moc-main, and Salmon and Ody's, but each failed to act, and finding himself totally incapacitated for his employment he begged to have the radical cure performed. Accordingly, upon the 18th of May last, his bowels having been cleared by castor-oil on the preceding day, and by a lavement of tepid water on the morning of the operation, he was placed fully under the influence of chloroform. Previous to this I should mention that I had had prepared a piece of ebony, about three inches long, and of the dimensions of my forefinger, and coated it with gutta-percha. Near its apex a fine hole had been drilled, and through this hole a piece of Arnold's strongest ligature silk was drawn, leaving eighteen inches on either side. This plug was well smeared with cantharides ointment thinned down to the consistence of honey with glycerine. To return to the operation however, the hernia was thoroughly reduced, and retained in the abdomen by my colleague Mr. Croly, who was much in favour of this mode of procedure, and strongly advocated its adoption, a finger carefully pressing up the gut and keeping it from coming down.

Following the directions of Mr. Syme, with some slight modifications, I placed the fore-finger of my left hand upon the scrotum of that side, about an inch below the root of the penis, and with the pulp of the finger looking upwards, I lifted this portion of the scrotum, carrying it onwards through the external abdominal ring, and for a short distance up the canal. I then took a long vesico-vaginal needle mounted in a handle, through the eye of which one end of the ligature had been threaded, and guiding it along my fingers, carried it to the very top of the invaginated skin. I then depressed the handle, and forced the point out through the abdominal parietes towards the right, or umbilical side. The ligature having been freed, and the needle withdrawn, it was again threaded by an assistant with the remaining end of the silk, and the same procedure adopted upon the left side, the point of the needle brought out, and emerging through the skin at the distance of an inch from the first puncture, the ligature disengaged, and the needle withdrawn. The two strings were now pulled upon, so as to bring them perfectly fair, and the apex of the plug caused to press against the back of the finger which was still in the inguinal ring, and as it was carefully withdrawn so as not to disturb the invaginated skin, the plug was drawn up in its place, secured by being very tightly tied over a piece of gutta-percha of equal size, laid upon the abdominal wall, and upon which the two ends were firmly knotted. The other extremities, both of the plug and gutta-percha, were also tied together, and the integument and invaginated skin thus firmly compressed between them.

A grain of opium was now administered to the patient, and ordered to be repeated every third hour, if suffering much pain. In spite of the opium which was regularly given, there was great uneasiness, the feeling being that of intense constriction at the ring. Vomiting, too, occurred, but this apparently arose from the chloroform, and stopped spontaneously. The pulse rose rapidly after a few hours, and the heart's action continued to be very quick for the first

two days, with white and furred tongue. The urinary secretion was scanty, very high coloured, and passed with difficulty, in consequence of the horizontal position maintained by the patient. Upon the 20th of May, forty-eight hours after the operation, the abdomen was slightly painful on the lower and left side, but, there was not any tympany, or other peritonitic symptom. Redness showed itself around the point of exit of the internal ligature and purulent secretion followed. The scrotum was now directed to be kept smeared freely with lard, in order to prevent excoriation from the cantharides ointment that might come down with the purulent discharge oozing from the invaginated skin.

The diet for the first forty-eight hours was confined to ice, iced milk, and chicken broth. Upon the 21st of May slight rigors supervened, but these passed away, and the patient became quiet and tranquil, taking the opium only at intervals.

Upon the 26th, the bowels not having acted since the operation a tepid lavement of plain water was administered with good effect.

Upon the 30th of May twelve days after the operation, the ligatures were cut and the plug withdrawn from the inguinal canal; the counter-pressure was also removed. Purulent secretion had, for some days, been making its way freely down the plug. A pad and figure of 8 bandage were now daily applied firmly to the groin, affording a feeling of comfort and relief to the patient.

Upon the 30th of June the passage up the canal was pervious only for half an inch, a piece of wax bougie, when introduced thus far, creating pain, and being followed by bleeding from the breaking up of granulations. Upon the first removal of the plug, the same piece of bougie passed up freely for three inches.

Upon the 21st of June the patient was allowed to leave his bed, and walk about, and upon the 27th to return home. The pad and bandage were still daily carefully applied and worn until the 10th of July, when one of his old trusses, that would not formerly command the hernia, was taken into use.

Upon the 20th of July the patient came to me, stating that he was again at his business, doing it without any inconvenience. The bowels were also acting spontaneously each day.

Dec. 5th, 1871.—In order to be enabled to report to the Society the result of this case, I visited the individual to-day, and carefully examined the parts. Upon the left side there is now not the slightest trace of rupture, or even tendency to it; whilst upon coughing, impulse can scarcely be felt against the internal ring. The orifice of the invaginated scrotum has totally disappeared, and in its place is a cicatrix of circular form and of about the size of a vaccine mark. In a line from this, leading to the internal ring is a dense elevated structure marking the course of the canal, now filled with the invaginated tissues consolidated together. The hernial tendency upon the right side (which has not been artificially supported), has increased, so that the rupture has nearly become scrotal. The patient has accordingly been recommended to wear a double truss in future instead of the single, which I have advised him to continue, as its presence is not productive of any annoyance, and he still suffers from chronic cough as heretofore.

The advantages claimed by Mr. Syme for this mode of treating reducible hernia, with a view to its permanent cure, are certainly borne out by this case. It illustrates, "1st. That it may be executed by means which are in the possession of every surgeon, instead of the complicated, expensive, and not easily manageable apparatus, hitherto deemed indispensable. 2nd. That it may be accomplished with much more certainty through the secure guidance of a finger, than by trusting to a piece of wood for gaining admission within the tendinous ring. 3rd. That the two threads co-operating in their effect, render the chance of adhesion between the textures much greater than when attempted by the mere puncture of a needle."

## VACCINATION, RE-VACCINATION, AND INOCULATION IN INDIA.

BY JAMES C. DICKINSON,

Late Bengal Medical Service; Surgeon to the St. Mary-le-bone General Dispensary.

THE subject of vaccination, affecting as it does the deeply interesting question of public health in India, is worth studying by those who intend to pursue an Indian career. The beneficial operation has met in times past with very great opposition, and is still looked upon by the natives of many parts of India with distrust. It is objected to by some on religious grounds—others from tradition, superstition, or because they are priest-ridden. Inoculation again is preferred and practised by many, and on more than one occasion has received an unhealthy stimulus from the circumstance of vaccination having completely failed.

It has always been my opinion that vaccination to be successful in its results should only be performed during the cold season, *i.e.*, from the middle of October to the end of February, or thereabouts. In my own practice, I have never met with successful results in the hot weather. On the other hand, it has been asserted that vaccination succeeds all the year round, by men well-qualified to speak on the subject of seasonal vaccination. "Vaccination"—they say—obeys the same laws that govern variola, and from a series of tables very carefully drawn up by the late Dr. Bedford, we learn that, whilst in Bengal, the maximum of successful cases of vaccination occurs in the month most favourable to the spread of variola, the remaining seasons are, by no means, unfavourable. In the Upper Provinces, whilst the results in January and March are inferior to those obtained in Bengal, the remainder of the year is marked by almost total failure; thus assimilating, as far as we know, to the habits of small-pox, and finally that in the hill provinces no great change takes place throughout the twelve months." Considering the question of reason as still *sub judice*, I may observe that it is the invariable custom of surgeons in charge of European regiments to vaccinate and re-vaccinate in the cold weather. The Superintendent of vaccination also makes his annual tour round the circle, over which he presides—in the cold season, and the civil surgeons, also of each station, send out at this period their native vaccinators into the neighbouring villages. Careful supervision is exercised by the civil surgeons over the operations and returns of the native vaccinators—the former are examined to the extent of about ten per cent.—and the latter (the returns) are made into a monthly return, which, together with a report on the results of the operation—the efficiency of the vaccine matter, and any practical suggestions that may occur to him are forwarded to the superintendent. This statement briefly represents the machinery by which vaccination is carried out in India. There are, however, difficulties which militate against the operation being completely successful.

*The Lymph.*—This cannot always be depended upon, and is not always obtainable. Many surgeons get a direct supply of tubes of fresh lymph direct from England, and this, I consider, the best source. The superintendent supplies lymph on application, which is generally sent between glasses; or sometimes if it be at the commencement of the cold season, two or three scabs are sent packed in cotton wool, and sometimes ivory points.

The "scab" from a vaccinated arm is, I think, the favourite and recognised medium for preserving and transmitting lymph in India, and I have frequently received excellent ones from England. The "scab," when wanted for use, is moistened with water on the back of a plate. I may here observe that all statistics in reference to successful operations, in so far as I know, tally with the observations made in England: *viz.*, when the lymph is taken direct from the child about 90 per cent.; from tubes, 50; from scabs, 30; and from points about 10,

Possibly these figures may not exactly coincide with later observers, owing to the improvements that year by year take place in this department.

Arm-to-arm vaccination, as understood in England, is scarcely ever successfully carried out in India. I have, however, succeeded in establishing it in those villages bordering on large cities, as Benares or Delhi, where vaccination had been pursued for a number of years, and a certain number of converts had been made, as well as from the circumstance that the large proportionate number of vaccinations occur among the poorer classes, as the coolies, and the fact of their residence being in proximity to the Government vaccinators.

Moreover, in those countries where the operation is novel, and but little understood if not feared, such a thing as arm-to-arm vaccination is simply impossible, and hence it is that lymph in one of the forms just mentioned has to be used. The subject of re-vaccination, which, in India, received so great an impetus on the outbreak of the epidemic in 1864, is now recognised not only by the Europeans, but by many natives as a necessary and salutary operation. While the epidemic just alluded to prevailed in Calcutta, I attended a number of patients, besides being engaged in the shipping practice on the Hooghly, and notwithstanding I was daily brought in contact with many very serious cases of small-pox, I never contracted the disease, which I consider due to the circumstance of my being re-vaccinated at the *very commencement* of the outbreak. Re-vaccination, in my opinion, to be successful, should always be performed in the cold season. *En passant* I may observe that, since my return to England, my views as to the importance of vaccinating in the cold season, have received singular confirmation, inasmuch as some cases of vaccination and re-vaccination both in the child and adult were unsuccessful. They occurred in those very hot months of July and August, 1870.

And I would venture to lay some stress on this point, inasmuch as I think that, if attention were more particularly directed to this circumstance, some practical rules might be drawn up in reference to the advisability of all who can being vaccinated in England in the spring and winter.

Re-vaccination to be successful must be performed with moist (fresh) lymph, and if it takes properly, need not be repeated for some years at least. There is a great outcry about the evil results or after effects of re-vaccination. In my own practice, "intense itching" I found the most troublesome affection, and in a climate like India it gives rise to restlessness, want of sleep, &c., just as "prickly heat" does.

Porriço contagiosum I have seen in a few instances. Erysipelas of a very severe and alarming character happened in one case, but I satisfied myself that it was caused by drinking to excess.

Inoculation is still practised to a very great extent in India, though now that the Government are employing every legitimate means to spread vaccination, it is less common than heretofore. There was a time when the question was agitated as to whether inoculation ought not to be recognised, and the late Dr. Bedford published 184 cases of the sequelæ of small-pox, of which only seven were produced by inoculation.

Happily, however, the days of the "Ticcadares" (Inoculators) are numbered, and the education which the various medical schools of India afford, enable the natives to calculate the relative advantages of the sequelæ of inoculation, and the fact that every person infected by small-pox, whether by artificial or natural means, becomes the focus of contagion. I mentioned that some natives objected to vaccination, and I may add inoculation from false prejudice or tradition. They are called the "Itsha" families. Hindus who totally refrain from having recourse to any kind of protection whatever, on a tradition that in the days of yore, their ancestors were visited by small-pox without inoculation, which they interpret Itsha, or a favourable visitation of the goddess

Seetula, have thence made it a family rule never to adopt any kind of protection, by which they apprehend that the goddess will be incensed, and it is chiefly in these families that the malady first appears and spreads far and wide.

### LABOUR WITH PLURALITY.

By JOHN A. SPENCER,

Medical Officer Crossroads Dispensary District, Co. Donegal.

CASE seen at five o'clock a.m., 15th Nov., 1871, at Erra-rooey. Mrs. J.—, primipara, et. twenty-three, under-sized, light-haired, delicate-looking, tongue clean, pulse, 95. There had been vomiting; bowels costive; had passed urine shortly before; sounds of the foetal heart could not be detected, the waters, it was stated, had come away at midnight. The "handy woman" in attendance mentioned that the foot was coming with the head, and that she had tried to put the former up; a vaginal examination, however, disclosed the true state of affairs, the left foot protruding at the vulva, the breech presenting.

The friends were informed of the existence of a "cross birth;" the rectum was emptied by a purgative enema, and the woman was delivered of a small female child, which showed some signs of life at birth, but which died in spite of efforts prolonged for an hour.

On tracing up the cord to seek for its insertion, a "bag of waters" was found, instead of a placenta, and the head of a second foetus was diagnosed; the binder was loosely applied, and there being no indication to the contrary, the membranes were ruptured; after an hour's delay, a turpentine enema was given, which had no effect; three hours subsequently, no change having taken place, twenty-five minims of tincture of ergot were administered, and with an hour's interval, twenty minims more; the preparations necessary for the use of the forceps were now made. The head of the foetus at this time, was high up; the occiput was closely applied to the pubis, and the edge of the os—relaxed from previous distension could be felt around the vertex. More than two hours having elapsed since the exhibition of the first dose of ergot, the forceps (a short pair, 8½ inches, the only instrument at hand) was applied antero-posteriorly, and traction made in the proper direction; when the head, by these means, had been brought down a little, the blades were withdrawn, and re-adjusted in the usual obliquely-lateral way, and the woman was delivered at five o'clock p.m., of a healthy female child; throughout the entire "labour" there was little or no assistance from the uterus. No difficulty with the placenta; no after-pains. Mother and child are now doing well.

*Observations.*—The following points connected with the case, may be considered worthy of notice.

The inertia of the uterus from beginning to end was remarkable; the turpentine had no effect, neither had frictions, nor even the forty-five minims of the tincture of ergot (this same tincture was given to a patient not long since, after removal of the placenta, and she stated that she felt as much pain as if she was "going to have another child").

Although more than two hours passed from the time the first dose of ergot had been given, till the child was born, the latter did not appear to have suffered in any way; the fact that the ergot did not produce any appreciable effect on the uterus, may reasonably be offered in support of the opinion held by Dr. Hosack and Dr. Meigs, of Philadelphia, by Dr. Denham,\* late master of the Rotundo Hospital, and by others—that ergot acts injuriously on the child, only by causing contraction of the uterus.

It has been said, that in twin births, the breech is the most favourable presentation for the second; there is

reason to attribute the death of the first child (the breech in this case) partly, if not altogether, to pressure on the cord of its placenta, by the head of the second foetus in utero.

"Unequal development."—The first child was very small, and appeared to be badly nourished; the second, remarkably well developed, and large in proportion to the size of the mother.

The conduct of the labour after delivery of the first child, is a subject for consideration; it was based on the circumstances of the individual case, as well as on the laid-down rules, and in determining on a course of action, the following points had chiefly to be borne in mind:—First.—The moral impression of protracted delay on this young woman (whose friends, it must be remembered, had sent for a medical man as a *last resource*). Second.—The delivery of the first child having been artificial.\* Third.—The existence of uterine inertia; and fourth.—The risk of flooding.

Denman, writing on this subject, says: "I advise that the membranes should be ruptured soon after the birth of the first child . . . if the pains are feeble, or are altogether gone, there can exist little or no impediment to turn" . . . and again: "Where the birth of the second child is retarded by inertia, a dose or two of ergot, so as to stir up uterine action may be given; but if the specified time have elapsed, and our expectations be disappointed, we should not delay resorting to more certain means of finishing the delivery." Dr. Churchill says that we should not allow the passages to "recover their distension." Dr. Collins advises that the binder should be loosely applied after the birth of the first child, and that we should not leave the house till the second child is born; and further states, that "if after the lapse of half-an-hour, the membranes of the second child remain intact, they may be ruptured with advantage," if this does not succeed, he recommends turning—after a lapse of two hours, with no progress, or the forceps, "if the head is sufficiently low down."

Dr. Murphy says: "The too great distension of the uterus may weaken its tone, and if so, flooding may follow the delivery of either child." . . . "Delivery of the second child should be effected at once. You may give the uterus a little time to recover itself."

Here, the delivery of the first child was effected at about half-past eight in the morning; the membranes of the second were ruptured between nine and ten o'clock; the first dose of ergot was given at a quarter to two, and at five, the second child was born. With great respect for the opinions and deference to the experience of those authors above quoted, who advocate the operation of turning in such cases as the one under consideration, the writer thinks that the shock of this procedure is severe; and that the use of the forceps, by which the efforts of nature can be imitated, and those of the operator modified in accordance with the woman's powers of endurance, is better adapted to meet the emergency; that it is the *safer* practice in a remote country district there can be but little doubt.

### REMARKABLE FORMS OF DERMIC GROWTHS.

By J. MORGAN, M.D., F.R.C.S.I.,

Surgeon to Mercer's and to the Westmoreland Lock Hospitals, Professor of Surgical and Descriptive Anatomy R.C.S.I.

THE remarkable excrescences known as fici, strawberry, cockscorb, or warty excrescences, without doubt, occur most frequently in subjects suffering from constitutional infection; but whether they are capable of communicating syphilis, or any form of sore, is by no means proved. Patients who suffer from these pertinacious growths admit, as a rule, their origin from a suspicious intercourse; but, on the other hand, cases will occur where the interval of

\* "On the Effects of Ergot of Rye." *Dub. Quart. Journ. Med. Science.* New Series, No. xxi., Feb., 1851.

\* Dr. Meriman. Dr. Cook "Manual of Obstetrics," p. 181.

time has been too lengthened to allow of such a conclusion. I have certainly seen prodigious vegetations in men where there was no evidence of the female having had similar products, or having been in any way affected by venereal; and cases occur, where frequent intercourse with a patient suffering from these vegetations fails to give any disease. Persons of both sexes whose purity seems undoubted, occasionally, though rarely, suffer from vegetations, and the evidence certainly seems to show that there is no necessary connection between the growths and constitutional affection. But, on the other hand, instances have occurred to me of patients under hospital treatment, where some considerable time after the healing of the primary sore, and while still under observation, these vegetations have appeared in quantity, as the only constitutional sign, and then a rash, or some other evidences, of the taint would show itself. This I have witnessed repeatedly. There seems to be no difference in conduct or appearance between the vegetations from whatever cause they may arise; but there is a form accompanying the *later* syphilitic manifestations which is of extreme interest. The diagnosis between it and that dependent on malignant disease is a matter of some difficulty, as the syphilitic may much resemble the cancerous cachexia, and the accompanying evidences of taint, may be few, or be dubious, the similitude to malignant disease is sometimes most remarkable both in aspect and general history. The ordinary strawberry or foliated vegetations occurring about the genitals of either sex, present such characteristic appearances, that they can hardly be mistaken, if occurring in those who are at all young and in comparatively vigorous health, but when the patient becomes broken down by a long round of syphilitic manifestations, or from the stealthy deteriorating influence of the constitutional poison, then, the question of diagnosis becomes of some difficulty, and the probable result to the patient is one of great solicitude. Some remarkable examples have come under my notice, which I think are worthy of attention, and illustrate the great tenacity of such growths. The latter case I had under observation not only months but for years—the vegetations were situated chiefly in the fold of the groin, they were sessile, separable into packets, and when examined in detail appeared like coarse brush-like vascular bundles, much firmer than ordinary vegetations, and in places eroded at their base. There was an abundant secretion of sanious pus, and the appearances were those indicating a transition to the epitheliomatous character, and the following instance shows the position of these growths, with their general figure as situated in one groin:—

A patient, *æt.* twenty-eight, had been infected about seven years previously with sore and several suppurating bubos, had various constitutional evidences in the shape of pains, nodes, and sore throat, but never believed she had any rash. During the last four years, the labia had become enormously hypertrophied, and were removed by two separate operations. Remarkable vegetations grew from the groins and folds of the thigh, which endured persistently during two and-a-half to three years. Nothing could exceed their obstinacy—escharotics, and even removal by the knife, affording but temporary relief. The growths would persist, and sometimes become skinned over. A sheet of ulceration extended within the labia. The discharge was tolerably profuse, and acrid, sometimes excoriating the thighs. The patient finally died, though in tolerably good condition of body, of extensive syphilitic ulceration of the larynx. On examination of the growths they presented a transition appearance between epitheliomatous and vegetative excrescences. The mammillated and irregular appearance was very peculiar. The accompanying cachexia and the absence of any rash might have left very reasonable grounds for classing the vegetations as malignant.

These growths may present a very persisting and peculiar form from the anus, in late syphilis, and, in like manner, will endure for very many months in spite

of treatment. At the anus they seem to grow from the very margin, and are divisible, as in the last case, into bundles of firm consistence, and on a rather thickened base. They will sprout out at times, and at times diminish in size, apparently independent of any treatment.

Chronic vegetations of the groin of extreme obstinacy, occurring in the latter stages of syphilitic infection.

The following illustration shows an example of this very remarkable affection in a gentleman who gave every care to the treatment of this local disease, but not to the original infection. The growth had existed for nearly two years, and was slowly increasing in size, but from its position and liability to be rubbed, made the patient extremely miserable. The irregular and tufted appearance was very characteristic, the bundles being capable of separation, and being seized between the finger and thumb, there was no pain of a darting or a burning kind. The patient suffered from nodes and severe pains, and skin eruption, and was extremely debilitated. There was no specific glandular enlargements.

Remarkable chronic vegetations from the anal region, associated with a syphilitic taint.

In these two instances, which I had under observation at the same time; the appearances, structure, and conduct of the growths were identical, and in both cases very nearly the same stage of the syphilitic cachexia had been reached. In the female, *post-mortem* examination showed, in addition to the ulcerated larynx, extensive amyloid degeneration of the liver.

The removal of such tumours, if persistent and doubtful, is best effected by the knife or *écraseur*, where practicable the use of strong caustics, if vigorously and incessantly applied, will succeed in checking them, but seldom answers, as does the more direct operative interference.

Specific treatment seems to have little influence, but the yellow wash with opium and tannin has proved the most useful local application. Injecting the persulphate of iron solution in quantity by the hypodermic syringe into the centre of the growths is also advantageous, and will succeed where a small size only has been reached.

A form of round, smooth tumours, with a slight central depression, and a shining surface, occasionally occurs, more particularly in women, and seems intermediate between true warty and vegetative formations. Huguier has styled this affection, *dermoptosis*; others, an *acne varioliformis*; and it seems to be caused by an hypertrophy of the superficial sebaceous follicles, forming in time, fibrous or adeniform tumours of the skin; it is, in fact, a cutaneous hypertrophy and is most chronic and persistent.

I have recently met with a case of a transition between this form of disease and the chronic vegetative growths, I have just now alluded to and illustrated, which is very interesting, and is even more allied in appearance to a cancerous growth of the epitheliomatous form. The following illustration gives an exact measured representation of the natural size and appearance of this morbid growth, which was situated on the verge of the anus; the surface was curiously mammillated, and at some parts was covered with a thin opaline skin, and at other places ulcerated and wartlike.

Remarkable and rare syphilitic epidermic growth. Natural size.

The patient was infected about six years previously, and more than two-and-a-half years since first suffered from this remarkable excrecence; very shortly after, another formed on the back of the thigh, about the size of a florin, and another, nearly as large, on the belly. The latter presented more of a distinctly warty appearance than did that near the anus, and they felt hard where they were implanted. The syphilitic peculiarity of nocturnal pain was then intolerable, but at other times there was not much inconvenience. Nothing could exceed the pertinacity of these growths: the best directed treatment—iodide of potassium, or mercurial applications, were equally inert; arsenic had no effect; the knife and strongest caustics were alone of use, and owing to the extent of surface, these could be used but on a limited scale; the application of the carbo-sulphuric paste was

the most efficacious, when freely applied under the influence of chloroform; by perseverance, the growths were considerably reduced when the patient was last seen. The condition and the health generally were tolerably good, there was no other skin abection.

## Transactions of Societies.

MEDICAL SOCIETY OF LONDON.

MONDAY, DECEMBER 11.

DR. FREDERICK SIMMS in the Chair.

MR. CHURTON, of Erith, showed the head of a foetus, born in the seventh or eighth month. There was an absence of the cranial cavity. The brain, which was dark coloured, was contained in a pouch at the back of the head. The face resembled a newt's somewhat in appearance. The woman had been frightened when in the third month of her pregnancy by a newt crawling up her hand, which was placed on her hip. She looked into the newt's face, and was much frightened. He had known a mark like a blackbeetle on a child, attributed by the mother to a fright from a blackbeetle.

DR. KELBURNE KING, of Hull, sent up a communication to the Society, principally with a view of calling attention to what seemed to him to be the best method of performing the operation of excision of the scapula, so as to reduce to a minimum the danger of hæmorrhage; and because the operation has not been performed so often as to render individual cases devoid of interest.

Case I.—In the summer of 1869, H. R., æt. twenty-six, applied at the Hull Infirmary, suffering from a tumour of the scapula. He had noticed it some months, it was painful only when pressed upon by his clothing. There was felt above the spine of the scapula a round perfectly hard and solid tumour about the size of an orange, not painful to the touch, nor moveable, but firmly attached to the supra-spinous fossa, from which it sprang. Gradually it extended over the middle of the spine into the infra-spinous fossa—the use of the arm was now much limited. The pain, though not severe, was constant, and prevented sleep, and his general health began to suffer. The tumour appeared to be of a bony non-malignant character, so on October 20th, 1869, the following operation was performed—An incision was made along the whole length of spine of the scapula, and the attachment of the trapezius divided. Owing to the size of the tumour the bone was easily pulled forward, and the supra-scapular artery was divided and ligatured. Then placing the forefinger of the left hand on the axillary border of the scapula just behind the triceps muscle, when the pulsation of the dorsal artery could be felt, he entered the knife at the acromial end of the first incision, and cut downward to his left forefinger, and about two inches past along the axillary border of the scapula. Still pressing his finger on the dorsal branch he cut through the deltoid, and so exposed the scapular muscles, the long head of the triceps, and the scapular vessels and nerves. These last were quite out of the way, and still feeling the dorsal branch with the finger, he passed a needle set in a handle, and armed with a ligature, round the vessels and sufficient cellular tissue, and tied a firm knot—the subsequent steps of the operation were bloodless. The base of the acromion was divided by bone forceps, and the neck of the glenoid cavity by a saw; the tumour was lifted up and separated from its attachments by cutting from without inwards, three branches of the posterior scapular artery

were ligatured. The wound was dressed with carbolic oil, the ligatures came away without hæmorrhage, but there was a tendency for the lower flap to fall. The man went into the country, but died soon after of tubercular disease of the lungs.

Case II.—C. A. M., æt. eight. The origin of the disease in this case was referred to a blow, having been knocked violently against a lamp-post eight months before. Admitted May 24, 1871. The tumour, which until then had attracted little attention, caused a perceptible swelling over the whole of the scapular region, most distinct above the spine, where it formed a considerable projection, which on strong pressure, yielded with a soft crackling sensation. An incision having been made, the finger passed into a bag of fragments of bone and soft curdy matter—the last under the microscope was found to consist of large cells containing many and large nuclei. The child's health becoming much worse excision of the scapula was done on 17th June. The operation was similar to the one already described, very little blood was lost. Health improved, but the wound was prevented from healing up entirely by the projection of the clavicle; and in another such case he would recommend the removal of the outer portion of that bone.

After referring to descriptions of the operation by Mr. Skey, Sir W. Fergusson, Mr. Syme, and Mr. Holmes, and the stress laid upon the occurrence of hæmorrhage, Dr. Kelburne King contended that it was better to put all risk of danger out of the question by securing the vessel behind, or rather internal, to the border of the scapular head of the triceps muscle at an early stage of the operation.

DR. ROUTH read a communication on

#### THE CONTAGIOUSNESS OF TYPHOID FEVER.

The year before last a lady and her maid were travelling on the Continent. The maid suffered from a mild attack of typhoid fever. On her return to England the lady (æt. forty-two) took the infection, and had a characteristic attack of the same disease, her case being a severe one. The house was good, and the drains were sound, disinfectants were freely used. Four members of the family were attacked—the governess, and the eldest girl who slept in the room with her, the housemaid and cook who waited on them. Dr. Routh contended that the typhoid was imported from the Continent, and disseminated by some infection in this country, as there was no evidence of fresh infection.

In the discussion which followed, DR. RICHARDSON said that he remembered that in the Glasgow Royal Infirmary, so far back as 1846, cases of typhoid, now so called, were distinguished from cases of typhus, by their non-contagious character. Since that time he had never known an instance in which he traced typhoid to contagion in the common sense of the word. This was also the opinion of the late Dr. Barker, who had a large experience of typhoid, and ultimately fell a victim to it—the authorities do right in considering the case of H. R. H. the Prince of Wales as non-contagious.

Dr. Thorowgood, Dr. Broadbent, Mr. de Meric, Mr. Roger Harrison, Mr. Hanworth, Mr. Brudenell Carter, and others took part in the discussion.

#### THE SURGICAL SOCIETY OF IRELAND.

THE opening meeting of this Society for the Session of 1871-72, took place on the evening of Friday, December 8th, in the Albert Hall, Royal College of Surgeons. The President of the College, MR. WHARTON, in the chair.

The SECRETARY (Dr. Richardson) having read the minutes of the previous meeting,

The PRESIDENT delivered the Opening Address, which will be found at page 567.

MR. H. G. CROLY exhibited a specimen of a rare affection which he met with within the last few weeks, viz.,

#### POLYPUS OF THE RECTUM.

A girl, æt. nine years, healthy looking, was brought by her mother to the City of Dublin Hospital among the extern patients. The mother stated that the child had had repeated hæmorrhages from the bowels for a year; and on hearing the history of the case he expressed his opinion that there was a tumour in the rectum, probably of the nature of polypus. The child was placed sitting over warm water, and told to force down, when two tumours became protruded, the larger one being very vascular, with a narrow long pedicle. The child was placed on her side, and he (Mr. Croly) was about to place the chain of an æraser over the tumour when he found that the latter came off in his fingers upon twisting

it. There was hæmorrhage, and the smaller tumour came away almost more easily than the first one.

MR. CROLY said he had another specimen to exhibit, which was one of some interest, being a good example of what was known as

#### CHRONIC MAMMARY TUMOUR.

The patient, a woman, æt. thirty-five, was admitted to the City of Dublin Hospital at the end of last November. She had in the left breast a tumour lobulated and moveable; this tumour became painful during menstruation; there was no contamination of the lymphatic glands, and no appearance of cancerous cachexia. The tumour was two years growing. On examining the right breast he found a small tumour. He thought it belonged to the class of chronic mammary tumours, because of the history of the case and the peculiar feeling of the tumour. He had a consultation with his colleagues for the purpose of considering the propriety of removing it. The woman however was attacked with symptoms of hysteria of a very aggravated form. Her husband said she was of an excitable temperament, and within a week afterwards she was seized with very severe maniacal symptoms, and gradually sank and died before any operation was performed. He removed the tumour after death, and on raising it up found it moved completely on the pectoral muscle, and contained a number of cysts underneath, and on section it showed the characteristic appearances of these mammary tumours. The small tumour on the right breast was also characteristic.

MR. CROLY also exhibited the section of the femur and tibia of a young man, whose thigh he amputated within the last fortnight for disease of the knee-joint. He had displacement outwards of the fibula and the tibia, and complete disorganisation of the joint. The popliteal space was filled with matter, and the boy had symptoms of hectic. He amputated the thigh at the lower third, and the specimen now before the Society showed the destruction of the cartilages of the knee-joint and the infiltrated tissues of the popliteal space.

DR. JOLLIFFE TUFNELL read a paper on

#### THE RADICAL CURE OF HERNIA,

which will be found at page 568.

MR. G. H. PORTER said that in the only case in which he had performed this operation some years ago, as referred to by Mr. Tufnell, he had found it most satisfactory. The simplicity of the operation was a great advantage. He thought they were often more afraid than they need be of passing a needle through the peritoneum. In his case there was very little inflammation, and in Mr. Tufnell's case there was also very little inflammation. It was an important operation, and one that they ought to perform more frequently than they were in the habit of doing; for although they might fail to cure the hernia, they put the patient in a better condition, in a condition to be comforted by a truss, which, without the performance of the operation, would not be found effectual for its purpose.

MR. BUTCHER said the subject of the management of hernia was one of the greatest importance. With regard to the operation Mr. Tufnell had so carefully described, he thought a great deal might be done by operative interference in hernia. At the same time he would be exceedingly cautious of going up as far as the internal ring. If they could shut up the compartment below the internal ring, a moderately pressing truss would be found sufficient to control the hernia. He thought it important to say that it was their duty to avoid puncturing the peritoneum. They could not look on the lining membrane of the scrotum as peritoneum; he thought it was changed altogether in its character; and if the hernia came down, he thought if it were pushed well up and the needle inserted as Mr. Tufnell had described, a satisfactory issue would be obtained. He was not speaking without some consideration and information on the subject. Not long ago he operated on a gentleman with great success in that way. It was necessary that this gentleman should be in the saddle every day, and important to relieve the uneasiness he suffered even from the best constructed truss—and he believed the best trusses made were those of Mr. L'Estrange, but even with the best truss in some instances the hernia will force itself down. He operated on this gentleman, but he kept down well below the internal ring, keeping back the intestine, and the result was most satisfactory; and now with the slightest pressure of L'Estrange's truss the patient is able to take the most violent exercise. He (Mr. Butcher) did not approve of the invagination, and the shoving up, and the perforating of what came down below

the ring. They must keep below that, and if so the operation as Mr. Tufnell had described it, would be found a very successful one, and one from which no serious consequences need be apprehended.

MR. CROLY said the patient had tried every truss that could be worn, and had spent much money in instruments, but the hernia was not anything the better of them. He happened during a part of the time to be under his (Mr. Croly's) care but he thought it better that the operation should be done by the gentleman under whose care he had first been. It was a fact of considerable importance to remember that out of thousands of operations done on the same principle by Würtzer there was not a single death from the operation. They were not to conclude at all that by the operation for the radical cure of hernia in Würtzer's or Syme's operation, the peritoneum was to be wounded. In certain forms of hernia, there might be a risk of injuring the tunica vaginalis, but in ordinary cases the peritoneum was not injured by the needle which merely pinned together the invaginated portions. Würtzer recommended the smearing of the invaginated skin with unguentum cantharidis, in order to cause ulceration and ultimately adhesion. He thought it a great pity that in Dublin the operation for the radical cure of hernia was not more often performed. The operation of Mr. Syme was a simple operation, and in the great majority of cases a safe one.

MR. L'ESTRANGE said he had great experience of hernia, and he believed that a radical cure could be effected in many cases without operation. He could produce examples of radical cure from all parts of the world—in individuals from the age of three to sixty-eight years, and he could appeal to members of the society to corroborate his statement. His method of procedure was to manipulate the hernia until it went into the internal ring, and then he put on the truss, which compressed the internal ring. The instrument should be worn day and night to cause complete compression on the part and produce adhesion in the inguinal canal.

MR. BUTCHER said he never meant to convey that the peritoneal covering and the intestine should not be returned into the abdomen before operation. He did not approve of Würtzer's operation, for he had performed it, and failed; but with regard to returning the intestine within the abdomen, that was essential. He did not think it a light matter to strike the needle through the peritoneum. With regard to Mr. L'Estrange's trusses, for years back he had been advocating their use; he ordered no other and he had seen the happiest results follow their use. He had known a number of young persons cured by them; and even in the largest hernias they could be used with advantage and comfort.

DR. ALBERT WALSH said that a young lad, thirteen years of age, an active young fellow, fond of riding, had been under his care for hernia. A great variety of trusses had been tried with him, but none of them would keep up the hernia, and at last about eighteen months ago, he sent him to Mr. L'Estrange. Mr. L'Estrange put on his truss, and three months ago the boy was with him (Dr. Walsh), and had not the slightest appearance of hernia. He was so well that he was able to do without the truss. He thought it was a great mistake to give too much encouragement to operators. All operations were serious, particularly an operation implicating the peritoneum, and the last thing they ought to do was to recommend an operation unless it was absolutely necessary, as in Mr. Tufnell's case.

DR. I. BYRNE mentioned a case of a gentleman, thirty-five years of age, who put on one of Mr. L'Estrange's trusses and wore it for five years. One day that he was going on a walking excursion, having taken off the truss that he wore at night, he forgot to replace it with another, and went out. He found no bad result; and he lived for ten years afterwards without wearing the truss, and never had the slightest appearance of hernia.

DR. FLEMING said that he had performed Würtzer's operation with the apparatus lent to him by Mr. Porter, and with satisfactory results. However as the man was engaged in an occupation which required considerable physical exertion, he thought it advisable that he should continue to wear a light truss. Was he to understand that in all the cases alluded to that evening in which the surgeon had recourse to Syme's operation; previous efforts had been made by means of the truss to cause cure. He did not think it possible to reduce fully the hernial sac that had been for some time down in the scrotum and acted on by a truss. They might plug the ring with it, but he doubted the possibility when the sac had been

a long time in the scrotum, of returning it into the abdominal cavity.

MR. PORTER: I stated that I believed we were often more afraid than we need be of puncturing the peritoneum. I repeat the statement: I believe in the majority of these cases you can't perform this operation without wounding the peritoneum, and Mr. Syme states the same. In the majority of cases by Würtzer's operation, he says, the peritoneum is wounded, and he brings it forward to show the safety of the proceeding. We all know how we use a small trocar for dropsy, and without bad results.

MR. E. HAMILTON said he had had a large experience of hernia in dissecting rooms, and from what he had seen there of old long-established hernias, he was perfectly satisfied in his own mind that the sac of an old hernia could not be reduced. When the hernial sacs were long down, a mutual sympathy became established; and that which was formerly peritoneum lost all sympathy with peritoneum, and could be divided without any bad result, and this was taken advantage of by the surgeon. In an old hernia the sac might be divided with considerable impunity, but in a recent hernia, it ought to be reduced without injuring the hernial sac.

MR. STAPLETON believed the sac of an old hernia could not be reduced, but he believed it could be invaginated on itself. They could not send up an old sac because it was adherent to the parts.

MR. TUFNELL in reply, said he agreed with those who considered that when a hernial sac was long down it might be perforated with a needle or ligature with comparative safety. No doubt there was a risk, but where every truss had been tried without effect, the operation was justifiable. In this case, a year had passed away after the man first expressed a wish to have the operation performed, and it was not until he said, "If you won't do it, I will go to a surgeon who will," that he consented to perform the operation.

The Society then adjourned.

## THE SEWAGE QUESTION.

### SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. XXXIII.

[CONCLUSION.]

WE have now reached the end of our inquiries into the sewage question, and on reviewing the facts which have been brought to light we perceive the startling truth that however valuable the constituents of sewage may be, in theory, we have done our best to render them worthless, or nearly so, in practice; for through the instrumentality of our self-made sanitary authorities, we have so dealt with the subject as to have not merely destroyed the agricultural value of a product, which in all time has been regarded as a rich fertiliser of the ground, but have actually brought it into such a dangerous state of decomposition as to be an almost ungovernable nuisance. In the right order of Nature there can be no doubt that the proper destination of the excretions of all animals is the soil, where they find the means of becoming elaborated for the plant, which finally returns them to us as food. But this order of things has been perverted by the creation of difficulties, which our utmost ingenuity is unable to cope with. We strive, it is true, to restore in our own fashion the waste products of animal life to the mineral and vegetable worlds for which they are destined, and to which they will return at last in spite of our meddling interference, but we have so altered the natural and proper condition of things, as not only to hinder, but actually to embarrass the common operations of Nature.

We have drowned, for example, the materials intended for the food of the plant in water that ought to flow unpolluted into the river, and then we wonder that the filthy mixture defies our skill, and can neither be utilised nor purified by the action of land or water. In some cases, where large agricultural results have been achieved, as on the Craigentenny meadows at Edinburgh, all sanitary considerations are abandoned, and the sewage is allowed to flow upon the ground in such enormous quantities as to convert the locality into a stinking morass, which is a public nuisance; besides which the effluent water is so foul as not to be admissible into any decent water course, and therefore runs directly into the sea. On the other hand, when sanitary results are aimed at, as when the sewage is sprinkled upon the land by means of hose and jet, in the water-pot fashion, as was the case at Tiptree hall, at Rugby, at the Earl of Essex, and at the Voujours farm near Paris, the agricultural results were so unprofitable that notwithstanding the ardour and strong faith of its advocates, it was at last summarily abandoned. So that whether we wish to realise commercial profit or sanitary success we are alike in a difficulty as to the right means of dealing with the subject. Attempts have been made, as we have seen in the course of our enquiries, to balance the difficulties by working in a sort of intermediate manner, between the extremes of 300 tons per acre of land per annum and 10,000 tons; but, as might have been expected from such a compromise, the results have been neither profitable nor successful; for they have combined the difficulties, and realised the disadvantages of both extremes. It is abundantly evident, indeed, from the facts before us, that sewage irrigation can never be successfully practised except under peculiar circumstances, as where the land is far removed from human habitations; where the soil is so porous as to admit of free and almost unlimited percolation; where the effluent water can be discharged at once into the sea; where the sewage can reach the land without the aid of steam power, and of long and expensive carriers; and where the produce of the land—the rank sewage grass, will find a ready sale for dairy purposes.

On the other hand, the disadvantages of sewage irrigation, as it is now practised, are so numerous, and so formidable as actually to appal us; for in the first place, it often happens that the sewer outfall is so much below the level of the land, that costly motive power and expensive conduits are required for the transport of the sewage. Secondly: the necessary quantity of land (an acre for every 25 persons) is not always to be obtained at a reasonable price, within a reasonable distance; for the land must be porous, with a moderately level surface, a proper outfall, and not liable to subsoil pollution. Thirdly: in all cases the ground must be levelled, and thoroughly drained, and otherwise prepared for the reception of the sewage. Fourthly: there is the difficulty of disposing of sewage in wet weather, when the quantity is larger than usual, and when the ground is already loaded with moisture. Fifthly: there is the pressing and imperative necessity for continually, systematically, and thoroughly defæcating the sewage, so as to produce at all times an effluent water which can be freely admitted into the neighbouring water-courses without danger of polluting them. Sixthly: there is the serious disadvantage of the non-applicability of sewage to any other crop than grass, which can only be profitably used for dairy purpose.

Seventhly: the noisome character of the operations, and the filthy sodden state of the soil are undoubtedly dangerous to the public health, for a damp atmosphere reeking with sewage effluvia is known to be a prolific source of typhoid and enteric maladies. Eighthly: the subsoil water, if not properly diverted, is apt to reach the neighbouring wells, and render them unwholesome. Ninthly: there is the great probability of producing entozoic infection of both man and animals by the distribution of excremental ova upon the land and its produce. And, lastly; there is the admitted uncertainty of every practical question connected with the subject, so that it is impossible to say whether the soil should be light or porous; whether it should be drained or not; whether the sewage should pass through the land or merely over it; whether the distribution should be by open carriers, or by loose subsoil pipes, or by means of the hose and jet; whether the dressing should be large or small; whether it should be applied in summer or winter; whether the crop should be grass, or roots, or cereals; whether the grass should be eaten green, or dried by artificial heat into hay; and whether the produce is best suited for making flesh, or producing milk: in point of fact, there is not a single question relating to the subject, which the so-called practical men are able to answer in a definitive or satisfactory manner.

All these considerations lead to the conclusion that the present method of distributing sewage upon the land is eminently unsatisfactory, for it is wasteful, it is inefficacious, it is expensive, and it is dangerous. The right way of dealing with the subject is first to defæcate the sewage by means of one or other of the best precipitating processes, and then to use the clarified water upon the land if it be thought desirable, and if not to discharge it into a neighbouring water-course. In this manner the defæcation may be so conducted as to suit the special requirements of the case; for if the effluent water is to be employed for irrigation purposes, there is no need of such a careful and perfect disinfection of the sewage, as when the water is to be at once discharged into a neighbouring stream. By this means all desirable results may be secured; for not only may the necessary disinfection be so accomplished that the effluent water may be either used upon the land when the season permits, or discharged into an out-fall channel, but the precipitated matter may be so treated as to destroy the vitality of parasitic ova, and form the basis or compost of a merchantable manure. We thus secure the most important sanitary requirements, and the most hopeful prospect of agricultural success.

It is unfortunate that some of the Parliamentary Committees and Royal Commissions that have been created for the express purpose of dealing with this important question have approached the inquiry with a manifest bias in favour of some particular scheme, and with a preconceived opinion of the way in which the subject should be treated. They have, therefore, selected their witnesses and sifted the evidence so as to suit the particular objects in view. It is still further to be regretted that some of these commissions have been so formed as not to include a single sanitary authority of medical education and experience. What value, therefore, can be attached to the conclusions and recommendations derived from such a source? In one notable instance, where the evidence was fragrantly dealt with in an inquiry before a Committee of the House of

Commons, and where, to use the words of Mr. Ker Seymour, who brought it under the notice of the House, the chairman of the Committee (Dr. Brady) "passed by one whole class of evidence, and gave prominence to the evidence of persons who agreed with him," the evidence was, by order of the House of Commons, cancelled. Next to a reprimand at the Bar of the House, this was the most severe censure that could be passed on a Member of Parliament; and it is to be deplored that the same kind of partisanship is exhibited in more recent inquiries. We pass by the cost to the public of these unsatisfactory investigations, although, perhaps, it may not be out of place to quote the remarks of Lord Elcho in the House of Commons, on 7th April of last year. "We doubt," he said, "the advantage of spending so many more thousands of pounds upon this Commission (The Royal Rivers Pollution Commission) because, looking at the knowledge already acquired, we do not think that its sittings will be worth their cost to the country. Besides upwards of £3,000 a-year for salaries, £800 are charged for travelling expenses, and £700 a-year for the laboratory; and the expenses of reporting and printing are enormous." It would be interesting to the public if Parliament were to inquire whether the laboratory and its appointments are used for private as well as public professional purposes, and whether, if such be the case, it is in accordance with the rules of the House, or the conditions of the appointment.

Here, then, we leave the subject, and, in so doing, we put a final question—whether the present system of removing excremental matters from our houses by the agency of water has not created more waste, and greater sanitary danger, and more expensive litigation than any other system which the ingenuity of man could have devised? not forgetting that the water which is thus wastefully and irreparably fouled amounts to from 20 to 30 gallons per head of the population daily, and has been brought at great cost from the purest sources, and perhaps, filtered in the most careful manner. What other nation would have been guilty of such folly?

#### The Endoscope in Granular Urethritis in the Male.

DR. ROBERT NEWMAN, of New York reports (*American Pract.*), five cases of granular urethritis in the male successfully treated with the aid of the endoscope.

The instrument which he uses is that known as Desormaux's, with the lamp invented by Dr. Cruise, of Dublin. Repeated use of this endoscope has led him to make certain subjoined modifications:—*First*, The graduation of the tubes in spaces of an eighth of an inch, which allows of more accurate observation at the time, and saves trouble to the operator and pain to the patient in searching for the diseased parts in subsequent examinations; *second*, A similiar scale for the wires, whereby the surgeon is enabled to tell the exact moment when the mucous membrane is reached; *third*, A straight tube for examining the bladder of the female, its far end closed with a glass fenestrum, which prevents the entrance of water into the tube; *fourth*, A curved tube, closed, provided with a glass fenestrum at the curve, for the bladder in the male. The corresponding instrument in Desormaux's set has, as is known, a sharp angle or corner, which oftentimes gives considerable pain to the patient when being introduced into the urethra; *fifth*, Several holders, with sponges attached, to cleanse the parts through the tubes; *sixth*, Several small silver cylinders, which fit into a handle; these, when tipped with nitrate of silver previously melted, are used instead of the solid stick of caustic; *seventh*, Several small glass brushes, with which the solutions are applied.

Dr. Newman states that since writing the above he has succeeded in constructing an apparatus which enables him to sub-

stitute the light of ordinary gas for the unsatisfactory and unwieldy Cruise lamp. It can be attached very readily to an ordinary gas-burner, is portable, and furnishes a very elegant light.

He has also had made several short glass tubes, of different sizes and forms, with an opening either in the side or end. These are designed particularly for the exploration of the female urethra. The light is reflected by the forehead mirror, such as is used in laryngoscopy. These tubes afford a most convenient means of applying atomized fluids to the parts.

### THE CONTAGIOUS DISEASES ACTS.

WHATEVER may be the opinions of professional writers and readers respecting these Acts—and they are evidently very opposed to one another—it is natural for those who have given evidence, to wish their statements, if commented upon at all, to be fairly represented. Dr. Bell Taylor complains that the *Lancet* having attributed to him certain statements, refuses to insert his reply. Although we do not print the motto *audi alteram partem* at the top of our correspondence every week, we endeavour to act up to it as much as our contemporary. As Dr. Taylor is refused a hearing in the columns of the journal that assails him, we consent to publish his letter as follows:—

SIR,—As one of the witnesses whose evidence has been commented on by the writer of a special article on the Contagious Diseases Acts' Commission, I claim, from your sense of justice, space for reply. I stated, in reply to Mr. Rylands, that the examination of supposed prostitutes was conducted in the following manner:—"The woman is fixed in a chair, and her feet placed attached to moveable projections, the chair is then turned upside down, and the woman exposed freely in the most delicate manner possible to conceive." One or two reporter's or printer's errors, which the writer in question has italicised, such as putting *legs* into *slippers*, &c., are of no consequence. The above was my statement, and to that I adhere. I added that the whole procedure was an outrage that nothing human ought to submit to, nor have I seen any reason whatever to change that opinion. The author of the article in question, however, expresses his surprise that any member of the Profession should believe and repeat stories so utterly incredible; it becomes, therefore, necessary for me to adduce such evidence as may enable your readers to judge whether or not my description of the process is a fair one, and in accordance with the truth; and, fortunately, I am enabled

to do so by quoting the following description which I copied from the *Medical Times and Gazette* a few months ago: "The woman is told to climb up into a high wooden arm-chair, and her feet being placed in slipper-like projections on either side, a handle is turned by the surgeon, and forthwith the chair, rearing over backwards to any required extent, and the foot-pieces turning aside, the woman is at once placed in a perfect position for examination. A suitable speculum is now taken from a basin of Condy's fluid, and inserted into the vagina; a bright gas flame, with a concave reflector, is then held to the mouth of the speculum, which is moved freely about." It certainly does seem incredible that there should be a law in England to force women, who are neither criminals or diseased, to submit periodically to such a disgusting process, solely in order to ascertain whether they are fit for fornication. For my own part, I regard the whole procedure as an indefensible atrocity, and I should think very much worse of the Profession than I do now, if I thought that this opinion was not shared by many of the best among us. I am responsible for the assertion, that women subjected to these wholesale examinations, are exposed to risk from mediate contagion, and I am quite prepared to defend that opinion; and, also, that the English Acts are simply copied from the French, and as nearly as possible identical with them, the only material difference being, that the framers of the English laws have carefully omitted those clauses which in the French code are designed to protect women who are not common prostitutes from the despotism of the police. I shall be glad also to adduce overwhelming evidence to show that such regulations have failed in every known clime and age to repress disease. The writer of the article in question remarks—"that the argument attempted to be raised against the Acts, from the length of time that constitutional syphilis may remain uncured, ignores the fact that if primary syphilis is detected, and treated in time, we should have very little constitutional syphilis to deal with." Here the writer himself ignores the fact that the local lesion, in true syphilis, is merely an indication of constitutional infection, and that no treatment applied to primary lesion will suffice to prevent the constitutional infection, which has indeed already taken place, and of which it is merely an indication. This form of infection is, moreover, comparatively rare, and the only venereal malady which can on any plea be considered a matter of State concern. It is also so frequently impossible to detect the condition which communicates this disease in the female by any mode of examination, that Dr. Drewitt has observed it is impossible to keep it out. No better illustration of this fact can be given than the one furnished by Messrs. Puche and Fournier's tables, which show that out of 873 males who contracted true syphilis in Paris, 625 owed their misfortunes to intercourse with public prostitutes subject to the French regulations.

I am, Sir, your obedient servant,  
C. BELL TAYLOR, M.D., F.R.C.S.E.

We have explained our reasons for giving publicity to this letter. We may add, that it is with regret we have observed that on this question it is very difficult to meet with any calm and judicial estimate of the facts that have been adduced by the two parties that threaten to divide the country. One asserts, the other denies, and *vice versa*, until we are weary of the controversy. No doubt, medical men are deeply interested in this, as they are in other social questions; but those who have taken a part in it have apparently been as excited as non-professional persons. We wish, as Editors, we could succeed in imparting a little calmness to our numerous correspondents on the matter. The violence of not a few letters suffices to exclude them from our columns. We have during the past year inserted many communications on the subject, and should feel considerably relieved if we could regard the controversy as settled. We fear, however, this is not the case.

There has just been forwarded to the Home Secretary a memorial, signed by eighty-seven physicians and surgeons of eminence, maintaining the utility of the Acts. This is, no doubt, an important manifesto, though it

will very likely be met by a similar one from the opposing party.

The following is a copy of the memorial alluded to:—

To the Right Hon. H. A. Bruce, M.P., Secretary of State for the Home Department.—Sir,—We, the undersigned, beg to express to you the deep and continued interest we feel in the subject of legislation for the diminution of Contagious Venereal Disease. Firmly convinced, as we are, of the deteriorating influence exercised by this form of disease on the public health, and painfully familiar with the serious suffering which it entails on large numbers of innocent individuals, we are most anxious that in any forthcoming measure nothing should be done to weaken the beneficial sanitary operation of the Acts at present in force, which can be shown to have reduced the more serious form of disease by considerably more than one-half in the districts where they are in operation (see the evidence of Dr. Balfour before the Royal Commission). We especially wish to protest against the erroneous supposition that a personal examination is deemed by the women themselves either so degrading or repulsive as has been represented. We know, by long experience of this class, that they will flock in crowds to our public hospitals for admission, although the presence of a number of medical students renders the exposure far greater than in the private chambers of an institution appropriated for this purpose by the Act. There is no difficulty in obtaining their voluntary attendance for even public examinations when sick and incapable of further struggle with disease, but we know that, with rare exceptions, they cannot be induced to seclude themselves for treatment in the earlier and less painful stages of their complaints, when, for obvious reasons, they are most actively instrumental in communicating infection. We therefore believe it to be absolutely essential to the success of any Act of the Legislature on this subject, that it should provide effectually for the earliest possible detection and treatment of disease in public women, and we are unable to see how this can be accomplished otherwise than by a system of periodical examinations. If, then, Sir, we are warranted, by recorded facts, in our belief that the temporary seclusion of these diseased women in a more healthy moral atmosphere has been found to contribute in no unimportant proportion of them to their restitution to the paths of virtue; if, both physically and morally, they have been thereby raised in the scale of humanity, we trust you will not listen to a factitious opposition, founded upon a most imperfect knowledge of the character and altered nature of these women, and of the extent of the evils to be remedied. We conclude, Sir, with the expression of a most earnest hope that in any future legislation on the subject, the main principles of the Acts of 1866 and 1869 may remain unaltered.

#### AMERICAN DEGREES.

At Shrewsbury last week Thomas Andrews was charged with an infringement of the Medical Act, by falsely assuming the title of M.D. It was proved that defendant, who had been for some years a druggist in the town, had recently sent out a bill for professional attendance, had attached M.D. to his name, and had "M.D." painted underneath his name on a lamp in front of his door. For the defence it was shown that defendant had received a diploma of the Medical University of Pennsylvania; and Mr. Motterham, barrister, who appeared for the defence, contended that even if the college had no power to grant the diploma, if defendant believed that it had, the charge must fall to the ground, and cited cases in support of his view. He called Mr. George Lever to swear to the authority of the diploma, which he did. Being asked to read it (it was in Latin), the witness declined to do so, and subsequently said that the knowledge of Greek and Latin was looked upon as a secondary consideration in the Medical University alluded to. He visited the University, and attended lectures; but he believed diplomas, after an examination by a duly authorised Board in this country, were granted. He had

no idea, however, what the nature of the examination was. The Bench fined defendant £20, but granted, on the application of Mr. Motterham, a case for the superior courts.

At the same time and place Andrews sued Mr. F. H. Davis for £4 13s. 6d. It appeared that Andrews had at length obtained a legal qualification, but that the debt had been contracted prior to his doing so. The bill was handed up to his Honour, and was as follows:—

“Shrewsbury, November, 1871.

“Mr. Frank Harry Davies

“To Thomas Andrews, M.D.

“To professional attendance, medicine, &c., £4 13s. 6d.”

Andrews's solicitor, in spite of the statement in this bill, maintained that the charge was made only for medicine supplied as a chemist.

In reply to several questions the witness would give no further description of the diploma than that it was an American one, and reiterated that he was not charging as a medical man. The bill-head had been made out by an assistant since his examination.

The Judge suggested that the case should be adjourned, in order that the plaintiff might give particulars of his claim, and amend his bill.

This course was strongly objected to on behalf of the defendant. Plaintiff came there as a medical man; if he were such, he would be on the “Register,” and defendant would have no answer; if not, why was defendant brought there? He denied that he was instructed by any other person than the defendant, and objected to the proposed course, even if the expense was borne by the plaintiff.

The Judge, however, considered that the right course would be to give the plaintiff an opportunity of amending his particulars; and, in spite of a vigorous protest the case was adjourned for that purpose.

The two cases here recorded are very important to the Profession. In the first place it is now, we believe, for the first time set forth that a quack must have guilty knowledge that the American diploma under which he practises is a fraud. That proposition, if it be maintained, will be equivalent to a ruling that every person practising knows the schedule of the Medical Act, in which legal degrees are set out, and is aware that this sham degree is not therein contained, before he can be prosecuted for “wilful and false” misrepresentation. The second judgment seems to be a very curious one indeed. It is, that if a chemist furnishes his account for medical advice, he is, on second thought, allowed to go back on the transaction and write up a medicine bill for the amount, and thus enforce a claim under one denomination, for which he is legally incapacitated from making any demand under another. There is only one conclusion for all this, that the Medical Act is a stupid and useless piece of legislation, and as the conclave of do-nothings which it has created don't care to amend it, the Profession must be content to endure the encroachments of all forms of medical swindlers.

#### THE MEDICAL ASPECT OF THE FRANCO-PRUSSIAN WAR.—No. V.

*The German Soldiers.*—We have already noticed some of the points in which a material difference exists between the respective troops of the two great powers lately at war against each other. Before we pass on to other subjects in connection with the medical bearings of that war, how-

ever, it occurs to us to make one more brief allusion to what we find said and written regarding them.

The able and literally prophetic reports by Baron Stoffel on the state of the German armies, which he sent to his own Government from Berlin, where he was officially employed in the capacity of military *attaché* to the French Embassy, are probably familiar to many of our readers. If so, it will be remembered that in regard to the materials comprising the rank and file of each, he observed two points of advantage, neither of which existed in the other. In the army of France one of those advantages was in the greater number of *old* soldiers in the ranks; the other, the greater number of *old* non-commissioned officers. In the German army there were observable two points of superiority, which, as the event proved, more than counter-balanced those of the French, namely—military service is obligatory upon all, and the masses are better educated than are the soldiers of France; may we not add, than those of England either?

It is now only necessary, in addition to the remarks already made in regard to the soldiers of the French army, to observe that the evils arising from the law of 1793, by which military service became obligatory upon the male population, with certain specified exceptions, between the ages of eighteen and forty, was considered so obnoxious to the people, by the subsequent calls to supply the ranks under the Empire, that its provisions were modified in 1814, when it was replaced by voluntary enlistment, and the payment of fifty francs per man to the recruits. This plan in its turn proved unsatisfactory, and accordingly in 1818, at the instigation of Marshal St. Cyr, an enactment was passed, under which the army was henceforward to be recruited: 1. By voluntary enlistment; 2. By conscription; and, 3. By re-engagement of time-expired men. In 1832 a further change was made, which although perhaps commendable in theory, has unquestionably exercised a most injurious effect upon the army. In that year it became legal for men “drawn” under different numbers or divisions of the conscription, to exchange places, and, moreover, for men to *compound* professional service by payment of a certain sum. In 1855 a sum was set apart for the purpose of increasing the pension of non-commissioned officers, and soldiers retired from the service.

Although in the different codes of regulations above quoted the *military* age is laid down at twenty years, the fact is well known that during the late war many of the young men in the ranks were not above eighteen years of age, many others apparently not more than sixteen, and quite unfit, physically, for undergoing the hardships of a campaign.

Reverting for a little to the German soldiers, it may be observed in this place that in Bavaria and Wurtemberg, conscription takes place on the 1st of January, and includes all who, during the year then beginning, will attain their 21st year. In North Germany the liability to military service begins at twenty years and a half, but it appears that of those “drawn” for service, a very great proportion are rejected as being physically incapable, while on the last occasion a selection of the strongest of those in the ranks was made to fill the ranks of the forces advancing through France to Paris. Besides the drafts above alluded to, volunteers are received. Those who as such enrol themselves for three years, are permitted to do so at the age of seventeen or eighteen. A recruit of this description is permitted to select his own regiment, and to re-

main in his own district, during the period of his obligatory service, which in the cases of such men is completed by the time he attains twenty-one years of age.

No doubt the German is physically more powerful than the Frenchman, but the following extracts from some of the reports on their respective qualities may not be without interest:—

“The superior physique of the German soldiers has been dwelt upon by all who have written on the late war, and it is not to be questioned that to this superiority over their opponents is to be attributed their success in close combat, as well as in the duties of a campaign. It was not often throughout the war that hand fighting took place, but even when it did the odds were in favour of the muscular German. The lithe supple Frenchmen recoil like so much india-rubber before the straight, sturdy shoulder push of the Prussians. But India-rubber recovers its elasticity and rebounds, the French never rebound.”\*

“Of the power of the Germans for performing long marches much has also been said. They have been described as cheerful after getting over twenty-five miles of road, their knapsacks sometimes carried by themselves, sometimes placed upon light carriages for the purpose”

*General Administration in the French Army.*—In the remarks already made we have had occasion to notice some of the important differences existing in the armies of France and Germany, and upon the existence of which the issue of the late great contest has most undoubtedly to a great extent depended. But great as have been the differences already recorded, they have not exceeded in degree that observable in the “administration” of the respective armies in the field. Some of the more important failures in that of the French army are related in the correspondence discovered in the Palace of the Tuileries after the Revolution of the 4th September, 1870, and subsequently published. The examples for the sake of convenience will be best given in the order in which they occur. On the 14th of August, 1870, General de Failly telegraphed from La Marche, requesting the Minister of War in Paris to send to him shoes, shirts, and *tentesabri*, adding that a large number of men had arrived without tents (p. 433), yet it will be observed that this was almost immediately after the campaign had fairly opened. At Metz, on 20th July, the Intendant-General telegraphed that the troops had neither sugar, coffee, rice, brandy, or salt, and very little of either pork or biscuit (p. 438). On 18th July, at Bitché, there was no money either in the public treasury, or in the military chest (p. 438). On 21st July the officer commanding at St. Avold, telegraphed to Paris that although he had large quantities of useless charts, he was at the time without one of the frontiers of France (p. 439). On the same date General Michel telegraphed from Belfort that he had arrived there, but was neither able to find his brigade, or general of division; he asks what he is to do, that he knows nothing as to the whereabouts of his regiments (p. 439). From Thionville, the officer commanding the 4th Corps, reported on the 24th July that he was without either canteens or ambulances or waggons for the corps or staff, that all were completely wanting (p. 440). On the same day the Intendant of the 3rd Corps at Metz declared that he had neither engineers or artificers of the “Administration,” nor ambulance waggons or field ovens, and implored the Minister of War in Paris to help him out of his difficulties (p. 440). On 25th of July the Sous-Intendant

at Mezières reported that there existed then neither biscuit nor salt provisions (p. 440). From Sarrégemines the Major-General telegraphed that the organisation was very incomplete (p. 441). From Metz on the 26th of July there was, according to the Intendant, at that place an absolute want of bakers, the troops were therefore obliged to eat the biscuit which should serve as a reserve for 12,000 troops; no more than thirty-eight new bakers could be found (p. 441). On the 27th of the same month he reported that among other wants of the troops arriving there was that of tents (p. 441). On the 29th a telegram was sent to Paris from Metz that biscuit was needed to enable the troops to march forward, that camp equipment, *tentesabri*, blankets, water vessels, and mess tins were insufficient in quantity (p. 445). The Intendant of the 7th Corps at Belfort reported on the 4th of August that he was without engineers, workmen, or *train* (p. 444). At Verdun, on 7th August, wine, brandy, sugar, coffee, pork, rice, vegetables, and fresh meat were urgently required in case of a siege. On the 8th, the Intendant at Chalons reported that he had neither a ration of biscuit or of food for the field, with the exception of sugar and coffee (p. 446). On 10th of August General Canrobert telegraphed from Chalons to beg the Minister for War to remember that many fugitives, sick and wounded, were arriving at that place; that he was still unprovided with cooking or water vessels, bed-sacks, insufficient shirts and shoes, and asking for instructions on the subject of his deficiencies (p. 445). At Strasbourg, on the 11th, the authorities were without money to pay for food or comforts for the wounded in the neighbouring villages into which they were collected (p. 449). At Langres on 13th, it was reported that there were neither water vessels or mess tins for the Garde Nationale Mobile of the neighbourhood (450), and at Besancon on the 15th of the same month, eight battalions of mobiles were without an article of equipment, blankets, cooking vessels, water bottles, or mess tins (p. 430).

The correspondence of the *Daily News* relates the condition of the French in their retreat from Forbach; the road taken by them was blocked by waggons of provisions and clothing, the woods filled with stragglers (p. 31).

## Notes on Current Topics.

### Rhinoplasty—Taliacotian Operation.

DR. J. F. MINER, in the *Buffalo Med. and Surg. Journal*, reports a successful case of rhinoplasty after the *Taliacotian* operation. The patient, a young woman, when first exhibited to the class, was deficient in the entire lower half of the nasal organ, leaving the nasal cavity exposed and unsightly. Three months after the operation the patient was again introduced, with a restored organ, so perfect in all respects as not to attract attention as presenting anything unnatural. It has been examined by many surgeons of great experience, both in our own and foreign countries, who pronounce the result in all respects unsurpassed.

The experience in this case leads him to believe that the *Taliacotian* operation is very difficult and uncertain, and that, though successful in this instance in a remarkable degree, yet many partial or entire failures will accompany every such case of success. The risks of

\* Correspondence: *Daily News*, p. 277.

non-union, the liability to death of flap after separating it from the arm, the certainty that any change or pressure upon the delicate vessels which supply the part attached, will interrupt the circulation, or destroy the vessels altogether, constitute sources of entire failure; while miscalculation in the size, shape, and adjustment of the new material is liable to cause failure in obtaining proper contour of the organ. The whole procedure is attended by difficulties and uncertainties; but if attended by success in one case, the achievement will amply compensate for several failures.

#### Medical Teachers' Association.

At the last meeting of the Council, it was resolved that, as the Association had now for four years satisfactorily performed the objects for which it was originally instituted, and as it did not appear that there were any points connected with medical education requiring the special attention of the Association, it would be expedient that the Association should for a time suspend its meetings.

It was further resolved that no change should be made in the constitution of the Association, the existing officers remaining in office, but that no call for subscriptions for the ensuing year should be made upon the members unless the Association should resume active work.

It was further resolved that the officers should be empowered to call a meeting of the Council should necessity arise, and that they should immediately summon a meeting on their receiving a requisition signed by three members of the Association.

#### Houses Without Drains.

WE have several times called attention to the infamous deceits practised by unprincipled builders and contractors, A little while ago, we showed that whole terraces were built without proper foundations, and that no proper provision for sewerage was made. We now hear of another case which we give on the authority of a contemporary.

The *Parochial Critic* says:—"A startling fact will soon be inquired into—that in the parish of Lambeth there are new houses having only sham drains, and those houses occupied! They are fair to the eye, with all the appliances for drainage, but no connection has ever been made with the main sewers! It is one of the grossest and wickedest pieces of deception that ever came to our knowledge. Most shocking is it to think of families occupying houses standing, as it were, in cesspools that are increasing in size and poisonous power every day. And what makes it more alarming is a well-grounded suspicion that the particular houses we refer to are not the only ones having sham drains. No wonder that typhoid is so often found lurking in the parish—that little children look sickly and feeble—and that fever is so frequently fastening upon the poor. If the houses are not sold, a proper punishment to the builders would be an order to pull them down, or one to prevent occupation for twelve months."

#### The Late Dr. Davidson.

THE death of this gentleman in the Middlesex Hospital, where he filled a resident office with great credit, and where he died from typhoid fever, contracted in the discharge of his onerous duties, has given rise to the following resolutions of the Medical Committee and Weekly Board:

"The Medical Committee desires to express its great regret at the death of Dr. John Davidson, late house-surgeon and resident physicians'-assistant, whose intelligence,

devotion to duty, high principles, and amiability, won the esteem and respect of the whole staff."

"The Weekly Board desire to record how cordially they unite with the expression of sympathy with the Medical Committee at the death of Dr. John Davidson, and their thorough appreciation of his most excellent character and services."

#### Preserved Meats.

A CAPITAL pamphlet by Dr. James Bird has recently been published by Mr. Hardwicke. It shows that the various cooked meats sent to this country from Australia are both wholesome and palatable, constituting an important addition to the food supply of the people. There is, however, another way in which the food supply of the country may be increased, about which we have often reflected, and which we are happy to see has at last been suggested by our admirable contemporary *the Globe*. This is the proposal to send meat to this country, from places whence the voyage is not to long, without any preservation at all. Last week *the Globe* remarked:

"At Halifax the ordinary prices of butchers' meat are not very much in excess of those ruling in Australia; and we do not see why the prime portions of the carcasses of sheep and cattle, leaving the heads, necks, shoulders, and houghs behind, should not be available for the supply of the manufacturing districts, and even of London itself. The passage from Halifax to Liverpool varies from eight to ten days. A few hours more would distribute the meat in the provincial markets, or take it to London, and in cold weather it would be improved rather than deteriorated by being kept so long, while before transit in the warmer season the beef might be salted and the mutton dried. The expense of freight would be far less than from Australia, while the cost of tins and artificial preservation would be altogether avoided. Even if only used in Liverpool, Manchester, and other manufacturing towns, it would, as a matter of course, increase the supply of beasts, and lessen their prices in London. Surely this proposed means of procuring good meat on reasonable terms for the public should at least get a trial. It requires but small capital, is attended with little risk, and, if successful, would prove most remunerative to the undertakers. But of all things, it would be necessary to have special depots for its sale, for if it fell into the clutches of the butchers, it would be dealt with in a manner to ensure its condemnation."

#### A Pharmaceutical "Mrs. Harris."

A CORRESPONDENT has favoured us with a documentary exposure of one of the medical swindles which are becoming now a matter of extra-professional notoriety.

We all know of the obscene quack—retired clergyman—or institute secretary, who gives his marvellous recipe for pure philanthropy and without charge. One of these fellows, who calls himself "The Medical Reform Society," advertises that he will forward free to all applicants an excellent botanic recipe for indigestion and liver complaints.

The dyspeptic who answers this advertisement, receives in return a prescription of "powdered Susquehanna root, sulphate of quinine, and extract of sarsaparilla" with the following moving exordium:

"Persons requiring this remedy, are strongly recommended to purchase the ingredients, and prepare it at home, and in no case entrust to a druggist the duty of compounding it: the interests of druggists being so closely identified with the allopathic system of Latin prescriptions and mysterious designations of the simplest articles, is naturally opposed to the present Medical Reform Movement."

It appears lower down in the said bill, that the Susquehanna root cannot be obtained in the United Kingdom, and therefore the Society, for pure philanthropy, encloses three drachms. But unfortunately the philosopher's stone is *not* enclosed, but a little notice is sent instead, to the effect, that "the committee regret to state that in consequence of the immense number of applications, the Society's stock of Susquehanna root is exhausted. A fresh supply is on its way from America, and is expected in two or three weeks: on its arrival, applicants will be supplied as hitherto gratis. The Society have, however, a considerable quantity of pills on hand, and so forth. The usual postage stamp remittance."

Of course it is unnecessary to say, that the Susquehanna root is a myth whose function is to lead up to the two-and-eightpenny box of pills.

### The Use of the Milk of Cows suffering from Typhus.

THE question has already been debated as to what injury may be sustained by the use of the milk of cows suffering from typhus. M. Husson has made the matter the subject of a communication to the Paris Academy of Science. Having analysed the milk of twenty-two animals, both in health and typhoid disease, he found:—

1. That neither milk nor meat are capable of transmitting typhus to man, or to any animal, except a ruminant.

2. But even in the first stage of the typhus, when the yield of milk is still normal, it ought not to be used as an aliment for young children, in consequence of the modification it undergoes in its constituents.

3. Towards the end of the disease the cream part of the milk disappears almost entirely. The nitrogenous materials, on the other hand, increase, and are soon found to be mixed with sanguinolent matter, and frequently agglutinated particles of mucus and pus are seen in it.

### Conversion of Albumen into Urea.

M. RITTER has sent to the Paris Academy a note on the transformation of albumen into urea under the influence of slight oxydation. These experiments confirm absolutely those of M. Béclamp, upon which doubts have been thrown. We learn, therefore, that it is possible to obtain artificially the metamorphosis which operates in the normal act of nutrition upon the albumen and fibrin introduced into the stomach.

### Is Interstitial Corneitis a Syphilitic Lesion?

M. PANAS has, by a communication to the Surgical Society of Paris, challenged Mr. Hutchinson's statements on this point. From his observations he draws the following conclusions:—1. That the syphilitic origin of diffuse keratitis, described by Mr. Hutchinson as *heredo-syphilitic keratitis*, may be doubted. 2. That the configuration of the teeth, said to be proper to this disease, is far from being constant. When it does exist it is identical with conformation of teeth in rachitis. 3. The name of *diffuse cachectic keratitis* is that which describes the disease best. 4. The medicine which seems to exercise the most beneficial effect is iodide of potassium; mercury is contra-indicated by the cachectic state of the patient.

M. Panas perfectly expresses the result of our own ex-

perience of the class of cases referred to by Mr. Hutchinson. Many patients suffering from interstitial keratitis present no symptoms of syphilitic taint; many patients present the peculiar conformation of the teeth without either corneitis or heredo-syphilis; and lastly, the mercurial treatment of the disease has been, with us, by no means satisfactory. Mackenzie's connexion of the corneitis with scrofulous cachexia seems to be the true solution, and the treatment of iodide of iron the most effective.

### Concealment of Contagion in Foreign Ports.

It appears that an extension to foreign ports of the principle which condemns any person who knowingly conceals the existence of epidemic disease in his house, and thereby imperils the lives of those who may unwittingly come in contact with it, is much to be desired. The last statistical report of the health of the navy contains the following paragraph:—

"The culpable concealment of the prevalence of epidemic diseases in foreign ports by the local officials has frequently been alluded to in these reports. The only safeguard against this would be vigilance and prompt action on the part of our consular establishments when any of our men-of-war were signalled as approaching the harbour. Unhappily this does not appear to constitute any part of consular duties, and our vessels for the most part are first made acquainted with the existence and prevalence of infectious diseases by their sudden appearance amongst the ship's company."

It ought hardly to be necessary, one would think, to issue a special order to British Consuls abroad that they should warn Her Majesty's ships of their approach to the dangers of epidemic disease. It appears that this simple act of humanity is not done because it is not in the list of a Consul's business, yet, the inquiry as to the state of the port is an obvious precaution which any sensible ship captain would adopt before taking his crew into danger, and it is not too much to expect that the commanders and medical officers of the Queen's ships should ask a few questions before they send their men ashore.

### Free Trade in Physic.

THE *Australian Medical Journal* utters the agonised complaint that "the whole population are rapidly becoming either club or hospital patients." "The provisional Committee of the Protestant Alliance Friendly Society [which we take to be an insurance company] opened a lodge, and initiated ninety-eight candidates. There are in both lodges as many more enrolled, who could not be initiated, owing to their not having passed the required medical examination. About the same time a medical man was applied to, to act as examiner. He remarked that he should be happy to do so, and wished to know at what rate he would be paid for his services. The reply was, that it was never contemplated to pay any fees. In other districts the examinations had been made by gentlemen, on the strength of their expectation of being afterwards appointed medical officers to the lodges. The promoters of the movement regarded the distinction of a surgeon being applied to, and permitted to conduct the examinations at all, quite sufficient remuneration for any trouble encountered! The gentleman to whom the application was made did not accept this distinction, but he found himself quite solitary in his refusal. The committee had no difficulty

whatever in obtaining as many honorary medical examiners as they wanted."

As a corollary to this statement the following advertisement appears in the *Melbourne Argus*: "Wanted, a Resident duly-qualified Medical Practitioner, to attend the members and families of lodges and tents in and near Whittlesea. Tenders will be received on or before July 31, by the Rev. H. C. E. Morris, Whittlesea."

The Profession in Australia are enjoying free trade with a vengeance, and we see no sign which should give us any omen that we in Britain may not come to the same complexion before very long. If it should be so, we cannot complain, for whatever hardship individual members of the Profession may endure, they would no doubt be treated to the stone if they were confidently to ask political economists for bread.

No doubt all this is grand political economy, but it is nevertheless the worst of policy, the greatest of injustice, and the most one-sided system. If Mr. Gladstone's lamb, the "working man"—that most inconceivable of political bores—were to hear of his neighbouring labourer taking the work for nothing which he should be paid for, or of his own personal job being sold out of his hands to the highest bidder, he would meet the emergency in a dozen hours by stealing his competitor's tools or blowing him up—not figuratively, but actually—with gunpowder.

If he were to resort to those forms of persuasion which are now recognised in England as peculiarly his own, it would be, in Mr. Gladstone's eyes, a very allowable weakness. He would appear only as an injured innocent exercising the right of a free Briton to conspire and combine, and an Act of Parliament would be speedily made to protect him from the impertinent intervention of the law.

Is the Medical Profession expected to take the same road to remedy? to ratten contumacious members or mob them in the street? If they cannot do so, we submit that medical free trade is a humbug, and that as buyers of medical advice cannot be expected to judge between good and bad work, free trade is ridiculous.

We do not, of course, ask for a law to remedy the difficulty, but, if not too aspiring, we might hope that committees and boards would recollect that they are supposed to be dealing with gentlemen.

Whether "gentlemen" guardians are mindful of that fact is indicated by a little episode reported to us by a correspondent. A Mr. Curling, at Abbeyfeale, in the county Limerick, who, we believe, acts as agent, or something of the sort, to some magnate in that neighbourhood, persuaded the board of guardians of which he was chairman into passing a resolution that the salary of the medical officer should cease if he became ill enough to have a *locum tenens*. On the next board day, the chairman being engaged in the congenial occupation of dispensing the chimney-sweeping patronage of the workhouse, entered the following in the minutes:—"Tender accepted on the distinct understanding that in the event of John Barry (the sweep) becoming unwell and being obliged to go to the sea-side or to Lisdoonvarna, for the benefit of his health, the guardians will not pay another for any work which he may be called upon to perform." If smutty faces go along with smutty manners, we should say that John Barry need not go outside the Board-Room for a *locum tenens* if he should fall ill; and we should hope, for the sake of the Union, the interregnum would not last long.

We further observe that this Mr. Curling has resigned his office because the guardians were restive under his whip, and objected to starve the doctor. We hope he will exercise himself during the leisure thus afforded him in the unwonted endeavour to learn how to behave himself when he has to deal with a member of a gentleman's profession.

### The Guinea Fee in Ireland.

THE *Journal* of the British Medical Association has, we observe, taken in hand an agitation to reduce the medical *honorarium* in Ireland from a guinea to two and sixpence. It publishes in its last issue a long letter from "an ex-officio guardian" in favour of this movement. The experience of this correspondent enables him to say that "with the exception of the well-known heads of the profession and some of the hospital physicians and surgeons, a guinea or a pound is not the fee, at least not the fee per visit that they do receive in Ireland, and that five shillings is much nearer the amount." And further more, "If every dispensary doctor in Ireland would make known to his committee that he would take a fee of 5s., or in certain cases even 2s.6d., it would very much curtail the issue of dispensary tickets." And in support of this proposition the "ex-officio guardian" informs us of the interesting fact that when a dispensary became vacant in his Union, he was one of those who "endeavoured to obtain a physician who would agree to take 5s. fees. Several of the candidates declared that it would be *infra dig.* to do so, but the guardians, of course, found the sort of man they wanted, who, we are informed, "finds it very much to his advantage."

We rather think the medical men of Ireland, even the dispensary men whom the correspondent of the *British Medical Journal* mentions in such a slighting tone, will decline to have the value of their services assessed by the extra-officious guardian, or according to the scale which is current in the British Medical Association. Anyone who thinks over the subject must know that uniformity of fee is a nonsensical proposal and an unwarrantable interference with private feeling. A man may stand out for his guinea if he finds that the demand for his services, or the plenitude of his pocket, or of the pockets of his patients enables him to do so; or on the other hand, he may descend to the half-crown minimum if his time hangs heavy on his hands, or if he is very hard up, or if his clients are poor, but what right has any man or journal to say that the doctor who is placed under the more desirable circumstances ought to reduce his *honorarium* to the same level as if he lived under the less fortunate conditions? The "ex-officio guardian" ought to know that he and his co-guardians have no right whatever to ask from any candidate for a dispensary a guarantee that he will work for a stated fee. He is bound to select the best man who possesses certain stated qualifications of which a 5s. fee is not one, and any Board of Guardians which exacts such illegal undertakings is prostituting the interest of the sick poor to that of the farmer who they consider ought to pay five shillings, but is usually well able to afford the guinea when he chooses.

AMONGST the gentlemen ordained by the Bishop of Ripon last week, was Dr. Henry Scott, a licentiate of the Royal College of Physicians. He was licensed to the curacy of Morley St. Peter, Leeds.

THE cholera continues to rage at Constantinople and St. Petersburg. In the first of these cities the latest reports inform us of an increase in the number attacked.

Two magnificent specimens of arcellites have been presented to the Paris Academy of Sciences by the Danish and Swedish Governments. One of these falling stars is 40,000 kils. or about 36 tons in weight.

WE are sorry to have to record an alarming increase of small-pox in Birmingham, Norwich, Nottingham, and several other large towns. In some cases the hospital accommodation is totally inadequate.

A CORRESPONDENT of the *Leavenworth Journal of Pharmacy* reports the result of an examination of a specimen of opium, purchased from a wholesale house which boasts that the opium sold by them is selected by their agent at Smyrna. One pound and a half of the opium in question was found to contain four ounces of gravel mixed with a few particles of iron pyrites.

CHLORAL in cod-liver oil is said by an American contemporary, to render it much less nauseous, and prevents the night-sweats of the phthisical patient, induces sleep, and creates appetite. The pure chloral-hydrate crystals may be added to cod-liver oil in the proportion of ten grains of the former to one hundred and ninety of the latter.

TRUE bills have been returned by the grand jury on both counts, of wilful murder and feloniously administering poison, against Miss Edmunds, the notorious Brighton poisoner. It will be remembered that the accused—a young lady of position—mixed both arsenic and strychnine with a large quantity of sweetmeats, cakes, &c., giving them indiscriminately to grown up people and children, apparently without any criminal motive.

It is stated in a recent number of the *Birmingham Morning News* that injurious results have followed the use of a disinfectant supplied to the town of Wolverhampton by its authorities, and conjectured to contain carbolic acid. In one establishment where it was used, the *Pharmaceutical Journal* learns that the sickness of three men is attributed to the disinfectant, as well as the death of two valuable dogs.

## SCOTLAND.

EDINBURGH UNIVERSITY COURT.—A special meeting of this court was held on Thursday, to hear an appeal against the resolution of the Senatus regarding the rescinding of the regulations for the medical education of women. Professors Masson, Calderwood, and Bennett, spoke in support of the appeal. Professors Masson and Calderwood's arguments were similar to those employed by them on former occasions. Dr. Bennett alone had the satisfaction of introducing a fresh argument in favour of the medical education of women, and which from his point of view is certainly unanswerable. He has found it to be an excellent way of increasing his emoluments as a professor, and states that he will receive this year £160 from the females attending his classes. Professors Muirhead, Turner, and

Lister, spoke in opposition to the appeal. The court adjourned consideration of the matter till a future day.

SURGEON-MAJOR FASSON, Registrar of the Herbert Hospital, Woolwich, has been appointed superintendent of the Royal Infirmary, Edinburgh.

### HISTORY OF THE DOCTRINE OF CONSTITUTIONAL SYPHILIS.

BY DR. FERRARI, of Bologna.

(Translated with notes by C. R. DRYSDALE, M.D.)

From *Lo Sperimentale*, t. XXVIII.

As to re-inoculation, H. Lee (*Br. and For. Med. Ch. Rev.*, 1856), first of all pointed out how excessively difficult it was to re-inoculate the infecting ulcer, and this was proved by many other experiments arranged for the purpose. Fournier, in ninety-nine cases produced auto-inoculation only once; Puche, in 100 cases, succeeded twice; Laroyenne, once in nineteen cases; Rollet, six times in 100 cases; and Poisson had the same result in fifty-two cases experimented on; Diday believes that the greater or less capacity of the infecting ulcers to be re-inoculated depends on the period in which the ulcer is, from which the secretion is taken. He thinks the best time to succeed is when the ulcer is in the period of invasion. Bœck, however, affirms that all periods are suitable. Dr. Ferrari, of Bologna, thinks it is impossible that one infection can succeed another, and holds it only possible that new infection shall take place when the virus has abandoned the organism—a most rare case, but one occasionally observed according to Virchow. As a general rule, the infecting ulcer is not re-inoculable, except when the syphilitic poison has entirely left the organism; otherwise we have to do with a mixed ulcer. The non-infecting ulcer is re-inoculable sometimes a thousand times on the same person. The infecting ulcer is usually accompanied by multiple and enlarged glands, whilst the non-infecting either causes no alteration of the glands in the groin at all, or, when it does, there is but one gland usually affected on one side, which suppurates and ulcerates. This peculiarity, which is a great addition to the facts already mentioned, in showing the difference between the sores, is warmly disputed by the unicists, who adduce several cases to prove the contrary. Davasse cites eighty-nine cases gleaned from Fournier's work, in which the bubo was not verified except in one-third of the cases. In twelve cases the bubo was not noticed, in thirty-nine it did not exist, and in three it suppurated, whilst it was resolved in seven cases. But this does not suffice. This writer remarks how, even when suppuration of the bubo took place, still constitutional infection sometimes occurred. Thus, in one observation, an ulcer appeared three days after connection, yet a suppurating bubo followed, and the patient had afterwards induration and syphilitic eruption on being inoculated from his own ulcer. (Record "Traité de l'inoculation," 1838.) In another observation, it is mentioned that an ulcer, which was followed by double suppurating bubo, was inoculable, and this was followed by pustules of ecthyma on the limbs and penis, and mucous plates in the genito-crural folds.

From the statistical tables of Bassereau, it also results that of one hundred and sixty-seven cases of ulcers followed by syphilitic skin eruptions, the ulcers were accompanied thirteen times by suppurating bubo. Melchior Robert observed in eighteen cases of bubo symptomatic of infecting ulcer, that they terminated eight times in suppuration; and Bertini reports the case of a child of four months in which there was seen an infecting ulcer with suppurating bubo. To these cases we may say, that they may be examples of double inoculation, with secretion from both kinds of ulcers.

Two years after Bassereau had published his doctrine concerning the duality of the venereal ulcer, Clerc, in a work entitled "Mémoire du Chancroïde syphilitique," 1854, also confirmed the fundamental principle of the said theory, adding, however, that as to the nosological process of the two ulcers, he believed that the secretion of the non-infecting sore was a true modification of that of the infecting one, by passing through a system already a prey to the syphilitic dyscrasia, and that the said ulcer is fit to transmit itself indefinitely without again resuming its infecting power; and he finds between the two ulcers the same analogy as exists between variola and varioloid, and between small-pox and vaccination, so that it appears just to him to call the infecting ulcer chancre, and the other *chancroïd*. But how much this theory is in fact without foundation may be judged both from history and from clinical experience. Syphilis is a disease of the tissues and the blood, and in the blood, as well as in the liquids of nutrition, there circulate diseased cells and nuclei, which, being deposited in the tissues, lower and disorder the normal function of the health-cells and nuclei, so as to lower the nutrition and weaken the organs and their functions. And is it not proved by modern researches that these contagious elements do not at all have their properties modified in the system? The contagiousity of secondary symptoms and of the blood is a clear proof of this. In 1860, Rollet, of Lyons, called attention to another fact. He observed that whilst the two ulcers might be both naturally and artificially inoculated, each in their own species, still their products may occasionally be found united, so as to form a composite ulcer, which he calls *mixé*. The theory of the Lyons' physician does not appear irrational, since we cannot see why this should not be so, and it seems also to explain well those cases of soft sore, which, according to some authors, cause syphilis. H. Lee, Baerensprung, and Sigmund, are, in fact, of opinion that in such cases "mixed chancres" have been present. The mixed ulcer is probably only a mixture of the two elements of contagion, as sometimes happens with the pus of gonorrhœa and of ulcers.

There were formerly some, before the days of Rollet, who attributed the varieties of syphilis to the objective variety of the virus. Such were Carmichael, of Dublin, who spoke of four poisons, which, although they all were capable of infecting the economy, some alone were incapable of being cured without mercury. But, as was natural, such ideas, finding no reception even in his native land, were very speedily abandoned. Langlebert thinks there exists but one ulcer-virus which is dissociated from the pus, and exists in the serosity. He thinks that the *soft sore* is "the result of the action of the globules of syphilitic pus on a healthy or syphilitic person," whilst the *infecting ulcer* is the product of the isolated action of the syphilitic serosity. According to him, the inflammation excited by the former sore is an obstacle to the virus entering the economy; but in this Langlebert is in error, since now-a-days, thanks to the information afforded by the microscope and experiments, it is not admissible any longer to seek for the active principle of any virus in peculiar modifications of the albuminoid materials of the serum or pus. We ought to look for them in the solids. The experiments of Prevost and Dumas on the fecundatory properties of the spermatozoids, and not of the fluid which surrounds them, as those recently made by Keber, Chaveau, Beccham, and Mouchy upon vaccinia, variola, and the pus of *Charbon*, show this clearly. Langlebert, in order to sustain his thesis, invokes the experiments of Beck, Köbner, and Bidentkap, of Christiania, who, irritating with powdered savine an infecting ulcer or a mucous-plate, which was in the way of healing, say that they obtained by inoculation of the purulent product, a non-infecting ulcer. To this it may be replied, that the assertion is far from having been verified, since the experiments have either not succeeded when repeated, or the lesion which ensued was only a simple wound, due to the local irritation of the pus elements arising from a hyperplasia aroused by the irritation caused by the powder,

Thus, after all, if we come to a general conclusion, it is desirable to admit that, among all the theories recorded, the one which has the most facts in its support is undoubtedly *dualism*. Dr. Drysdale thinks that this is the best essay on Duality which he has seen.

## Literature.

### SIMPSON'S WORKS.—VOL. II.

THE second volume of the collected works of the late Sir J. Y. Simpson\* comes to us with the name of the present baronet as its editor, and forms a handsome volume uniform with its predecessor which we noticed some time ago.

Not being a medical man, the editor would not apparently have undertaken this volume had his father's papers required more than careful selection and arrangement. The volume is, however, chiefly occupied with those subjects that have excited intense interest outside the profession, and on which probably the son has long occupied himself. The first part of the volume nearly half, is devoted to *anæsthesia*. Here we have most of the illustrious author's scattered papers on this subject, which is indelibly connected with his name, and nearly every one of which will prove most attractive to the reader. They are arranged for the most part in a logical rather than chronological order, but the editor has wisely placed the dates of original publication at the head of many of them. He remarks that, although a new work written by his father in later years would have perhaps given more prominence to some points and less to others than these papers do, yet they will be found to touch upon most topics that would have come under discussion in any new work on the subject.

This is true enough, but although a new treatise could not have been without its value, yet there is in these papers a freshness and an almost historically personal interest that would have lent them a charm in the presence even of a new work. They carry us back to the early history of *anæsthesia*, to the defences that it was necessary to put forward to the silly objections of well intentioned people, whose religious scruples were so delightfully demolished by the keen argument and biting satire of one who was far better informed and known to be quite as devout as those who had dared to attack him.

We suppose no one who has once read his replies to religious objections will ever forget, the triumphant way in which, by the union of common sense with great learning—theological as well as medical—he put them completely out of court, and closed by archly citing the first surgical operation, when prior to the taking the rib to form Eve, Adam was made to fall into a deep sleep, which Simpson observed should have been translated—coma, or some word exactly corresponding with *anæsthesia*, Hebrew, Greek, Latin, and other translations and authorities, were poured out by the medical writer in a style that startled his theological opponents, and in not a few cases completely silenced them.

It is really as refreshing as it is strange, to look over again these evidences of the many sided ability of the late baronet, and call to mind what power of pen he wielded.

Passing to the next subject, we come to the debate on hospitalism, from which the lamented author was called away before it was completed.

Six carefully arranged chapters on hospitalism contain all the author lived to write, in defence of his well-known views on the subject. These have recently been so fully before the profession, that they need not detain us further

\* "The works of Sir J. Y. Simpson," Vol. II. Edited by Sir W. G. Simpson, Bart., B.A., Scholar of Gonville and Caius College, Cambridge: A. & C. Black.

than to remark that no one can pretend to understand the position of this controversy, until he has mastered Simpson's views, and these are happily now accessible in the volume for which we thank Messrs. Black.

Then follow seven chapters on hermaphroditism, which is reviewed in a most thorough way by the author who had paid much attention to it.

The volume closes with the well-known proposal to stamp out small-pox and other contagious diseases, a proposal which in the face of recent epidemics retains its original interest for all sanitarians and medical men. The future probably will see bolder attempts at legislation against the spread of disease, and public opinion, in spite of much apathy, is without doubt growing in a direction towards legislative sanitary measures.

We close by expressing our pleasure with this volume, and our special thanks for a complete index to the subjects that has been carefully compiled and considerably supplied.

## Correspondence.

### TWIN BIRTHS.—DR. LUTHER'S REPLY TO DR. SHEIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall commence my letter on this subject by an aphorism after Bacon, "Art is but Nature's handmaiden, and if she usurps her mistress's place, she will cut but a sorry figure." Reducing the application of this saying to the matter in hand, is equivalent to stating that "meddlesome midwifery is dangerous," which no one denies. But the too often repeated inculcation of this doctrine created a school of timid practitioners, who are fast dying out, and have been succeeded by a band of reactionists, with whom I perhaps may class myself, who evince a predilection for the forceps, and manual interference in difficult or simply tedious cases. But, Sir, no educated practitioner or disciple of any school could uphold the course pursued by Dr. Sheil, of Killyleagh, which I condemn. He says he "passes over as altogether unworthy of notice the unwarrantable liberty I took in my opening sentence with the Doctor" (Query.—What Doctor? Himself?) I really thought my language was parliamentary. True, I did say his letter displayed "naiveté," a word equivalent to innocent candour. I beg his pardon, and hasten to withdraw the obnoxious phrase. His second letter (correcting the original text) leaves me in no doubt that it was mis-applied. But "litera scripta manet," and I appeal to your readers if Dr. Sheil, in his first letter, made any mention of the "repeated examinations made both night and day all the time, as the patient resided not fifty perches from his door." This, of course, materially alters the complexion of the case, reducing a very grave error to one of minor degree. His first letter would condemn him before any jury of gross negligence. After the birth of the first child, "the midwife called him aside," but what followed from the consultation he omits to say; but, presumably, she told him her suspicion that another infant remained in utero. Acting on this surmise he gave ergot, which was not quite correct, without he first ascertained that the presentation was normal, or at least not transverse. Then he waited for two hours, but no labour supervened, when he left the woman, and so far as any one reading that letter (the first) could judge, for three days, when he was sent for and found Nature more pitiful than is her wont, doing his work, and delivering the woman of an infant, which came into the world feet foremost. I suppose, had it been a hand presentation, Dr. Sheil would have awaited spontaneous evolution! If Dr. Sheil could not find the second bag of waters, and he doubts that I (Dr. Luther) could,\* neither could he be sure, unless by stethoscopic examination that a twin remained in the womb, for a more than ordinarily bulky placenta, and a relaxed uterus might cause one to suspect a second child was present. Introduction of the hand into the vagina would, of course, put the matter beyond doubt. This course Dr. Sheil should have pursued; as it turned out in his case, he would un-

doubtedly have met the bag of waters which he should have ruptured, caught a foot as the feet happened to present, and at once completed the delivery, which I maintain any competent accoucheur could have done, because the parts were dilated by the passage of the first child. I also maintain that, supposing in Dr. Sheil's case (no labour pains being present) that the hand, shoulder, or head presented, it would have been easy for any competent accoucheur to turn the child, while floating in the liquor amnii, and quickly deliver. I speak from experience, and have done it. The forceps, also, is useful, and easily applied in such cases. Of course, I mean when the head presents. Dr. Sheil seems to take umbrage at my assuming that it was a dispensary case. He takes care to inform an anxious public that it was a private one. I declare I did think, when I read his first statement, how he left his patient for three days with either a second child or a placenta in her womb (making no proper examination, it was guess-work), that she must be one of "those paupers whom nobody owns." I am yet of opinion that he ought to have either done something or called in a consultant. He thanks Providence that he had not me for an assistant, as I would indubitably have caused the death of mother and child. I can only say that, in seven years (since I came to Cappoquin) out of some 130 women whom I delivered, I lost but one (a case of placenta prævia), where copious hæmorrhages for months prior to labour, blanched the patient to lily whiteness. Delivery by turning was easy, but she died on the seventeenth day of anæmia. I reported that case to the Cork Medical Society. Three of the number were hand presentations after rupture of the membranes. In all, I saved the mothers—in two of those the children. Dr. Hartland, of Villierstown, called me into one of them. I have, also, called him in as consultant. Likewise, I have had the aid of Dr. Flynn, of Dungarvan. I have used the forceps at least a hundred times with success. If I deserve the appellation "fast," and I do not repudiate it in this instance, I retort by saying Dr. Sheil is a very "slow coach" indeed. But stay I must not catch the infection of bad manners from him. Enough!

I am, Sir, yours faithfully,

FRANCIS M. LUTHER, M.D.

Cappoquin, 20th Dec., 1871.

## Medical News.

The Medical Graduates Association of St. Andrew's University have presented Dr. B. W. Richardson, F.R.S., with a Gown and Hood of the Doctor of Medicine, as a slight acknowledgment of the services rendered by him to the Association during the four years he occupied the presidential chair.

Society of Apothecaries.—At a Court of Examiners held on the 21st inst., the following gentlemen, having passed the necessary examinations, received the L.S.A. Diploma, viz.:—Messrs. A. A. Beardley, of Grange-over-Sands, Lancashire; J. Chilcot, of Southsea; J. S. Cowley, of Upton-on-Severn; W. E. Griffiths, of Kensington; Frank Lungley, of Lewes, S.; W. E. Parkes, of Handsworth; J. E. Richards, of Ruabon; C. W. Sayer, of Sutton; G. C. Searle, of Tewkesbury; E. Sergeant, of Leeds; G. M. Sharpe, of Hunslet, Leeds; E. D. Wallis, of Bodmin; J. C. Wilkinson, of Spalding, and G. Willis, of Soham. At the same court the following passed the primary professional examination, viz.:—Messrs. Francis Thomas Atkins, of Guy's Hospital; Frederick Barrow, of King's College; J. M. Bromley, of University College; C. F. Bryan, of Guy's Hospital; E. J. Crouch, of Charing-cross Hospital; G. E. Keer, of Guy's Hospital; W. G. Nash, of Guy's Hospital; J. O. O'Brien, of Guy's Hospital; H. M. Page, of the Birmingham School of Medicine; D. P. Saer, of St. Mary's Hospital; and H. P. Tayler, of Guy's Hospital.

Dr. Prösser James has been elected a corresponding Member of the Academies of Medicine of Madrid and Barcelona.

Dr. Bamberger has been elected to succeed the late Prof. Oppolzer in the chair of Medicine at the University of Vienna.

The Italian profession is raising a subscription for a medal in honor of Professor Virchow.

\* "Quæ sibi quisque faciliâ factû putat æquo animo accipit auctore, veluti facta pro falso ducit."

Professor Erasmus Wilson, F.R.S., has presented to the Hunterian Museum a large specimen of the *Berardius Arunaii*.

Cholera has again broken out at Medina and some other places.

Small-pox is very prevalent in Philadelphia.

Diphtheria and the Exanthemata are prevalent in Vienna and some other parts of Austria.

Hamburgh is suffering from an epidemic of small-pox.

The Academy of Medicine of Paris has awarded the Amussat prize to Dr. Berenger-Férard for his treatise on ununited fractures and false joints.

A bust of the late Dr. Bright has been presented by his widow to the Royal College of Physicians of London.

Dr. Handfield Jones has been elected a Councillor of the Royal College of Physicians, London.

Dr. Beales, of Congleton, Chesh. has been elected a Justice of the Peace for Cheshire.

Dr. Alfred Meadows has been elected a corresponding Member of the Boston Gynaecological Society.

Dr. Tilbury Fox has been elected corresponding Member of the Dermatological Society, New York.

Sir James Paget and Sir William Fergusson, of London, and Professors Donders (Utrecht), Skoda, Hebra, Billroth and Sigismund (Vienna), Frederichs (Berlin) and Pelli (Milan), have been elected Honorary Members of the Royal Society of Sciences of Brussels.

**The Public Health.**—We learn from the Registrar-General's report that last week the aggregate mortality in London and 19 other large towns of the United Kingdom was at the rate of '35 deaths annually to every thousand persons estimated to be living. While the rate was 23 in Portsmouth, it rose as high as 62 in Wolverhampton. In the metropolis 2,263 births and 2,121 deaths were registered, the former having been one below, and the latter 491 above the average. There were 106 deaths from small-pox, 97 from measles, 37 from scarlet fever, 7 from diphtheria, 99 from whooping-cough, 42 from different forms of fever (of which 9 were certified as typhus, 23 as enteric or typhoid, and 10 as simple continued fever), and 15 from diarrhoea. The fatal cases of measles and whooping-cough showed a further increase upon the numbers in recent weeks. Excepting only the 15th of November, the mean temperature was continuously below the average from 2nd November to 13th December, both days included; the average daily deficiency in these 40 days was 7.1 deg. During the four days ending Saturday last there was an average excess of 2.5 deg. The increase of deaths last week was principally due to the greater fatality from bronchitis, to which 482 deaths were referred. Enteric fever has declined, and it is probable, the Registrar-General thinks, that the sudden increase of deaths from this cause was due to the sudden depression of the temperature which set in on the 4th and attained the lowest pitch on the 8th of the month. By inducing pulmonary complication the cold proved fatal to the system suffering from the fever in its advanced stages. This shows the importance of sustaining the night temperature as well as purity of air in enteric fever. With the mild weather the deaths will decline; but the great excess of the week arises from the accumulation of deaths from bronchitis and other diseases previously contracted. The following cases of complicated typhoid fever were recorded, in addition to those printed last week: a retired grocer, aged 33 years, died on the 15th instant, from "typhoid fever, 10 days, congestion of the lungs, 4 days;" a housekeeper, aged 53 years, on the 14th, from "typhoid fever, 13 days, pneumonia, 4 days;" a blacksmith, aged 37 years, on the 11th, from "typhoid fever and bronchitis, 13 days;" the son of a packer, aged 3 years, on the 15th, from "pneumonia and enteric fever;" the daughter of a gentleman, aged 7 years, on the 11th, from "typhoid fever, 3 weeks, congestion of the lungs, 8 days." To different forms of violence 66 deaths were referred last week. Of these, 51 were the result of accident or negligence, including 21 from fractures and contusions, 13 from burns and scalds, 12 from suffocation (including 10 infant cases), and 1 each from poison and drowning. Of the deaths from fractures and contusions 5 were caused by horses or vehicles in the streets. Four cases of suicide and two of infanticide were registered during the week.

**RICHMOND HOSPITAL.**—We understand that Dr. Gerald Yeo, of Dublin, has been appointed Assistant-Physician to the Richmond Hospital. The office has now been created for the first time, and we believe no salary is attached to it.

#### On the Therapeutic Value of Nitrate of Amyl :

By H. C. Wood, Jr., M.D., Physician to the Philadelphia Hospital.

It will be remembered that the conclusions arrived at in my paper upon the nitrite of amyl, which was published in the last number of this *Journal*, were, that in its action on animals it is an almost universal sedative, impairing the power of muscular fibre to contract, and the nerve to carry the motor impulse; lessening the reflex excitability of the spine, &c., and acting similarly, though much more feebly, on the centres of sensation and consciousness. As regards the circulation, its uniform action was to lessen arterial blood-pressure, although at first this diminution of force in the circulation is associated, at least in the dog, with a wildly excited action of the heart, without loss, and possibly even with gain, of power in the individual heart beat; in a little while, however, the heart itself manifests very plainly the sedative influence. It was further shown that the nitrite of amyl catalytically arrests oxidation.

These views are apparently not in accordance with the theories of some previous writers, that the nitrite acts upon man as a powerful stimulant. The systems chiefly affected, *i.e.*, motor and circulatory, are so consonant in their functions throughout the higher vertebrates, as to render it inconceivable that a drug which acted as a uniform depressant upon the lower animals should be a stimulant to man. Fortunately there have not been as yet any cases of human poisoning by the drug, and no one in experimenting upon man, that I know of, has as yet carried the effect far enough to produce serious spinal symptoms. Strychnia, woorara, calabar bean, &c., affect the motor apparatus of man as they do that of the dog; and there is no reason for believing that the nitrite of amyl differs from them in this respect. In a case of Dr. Da Costa's, the remedy, which he had used with good effect, was administered too freely during his absence from the city, by another physician, and produced alarming general prostration; the evidence, as far as it goes, therefore favours the view so strongly commended by *a priori* reasoning.

The most prominent symptoms induced when the nitrite of amyl is inhaled by a man in moderate quantities, are a sense of great fullness and distension of the head, amounting at last to severe pain, and accompanied by intense flushing of the face, a deep, laboured respiration, and an exceedingly rapid, violent action of the heart.

It is these latter symptoms which have been looked upon as demonstrating that nitrite of amyl is a direct vascular stimulant. I think, however, they have a different significance. The sensations in the head, and flushing of the face, are evidently explainable as being the results of the dilatation of the capillaries. The excited, violently laboured action of the heart is no indication of increased arterial blood pressure, since it is precisely what is seen in the dog, under similar circumstances, associated with lessened arterial pressure. If the windpipe of a man or animal be suddenly compressed, the same violent respiratory efforts, and the same wild tumultuous action of the heart result, and I believe from the same cause. When the nitrite is taken into the lungs, it instantly arrests or diminishes oxidation, and a thrill of impending suffocation runs through the system, in obedience to which the respiratory and circulatory organs gather up and exert to the utmost their forces. The central impulse sent to the cardiac and respiratory muscles, is at first much more than sufficient to overcome any direct action of the nitrite upon them, but the inhalation being persisted in, the impulse is constantly growing weaker, and the direct influence of the drug stronger, so that there soon comes a time, when the reverse is true, and the heart's power is more or less nearly extinguished. Any one reading the account of the experiments previously given, can note this as true in regard to the dog, and some who have administered the remedy to man with a little too great boldness, have been sorely frightened and puzzled by the same phenomenon. This loss of power comes on too quickly, is too great and progressive, and is too clearly connected with the presence of a certain amount of the nitrite in the system, to be explained as a mere secondary depression from over stimulation. Those who

have watched the steady whirr of the heart in a case of atropia poisoning, know how it often takes hours of intense action to exhaust the viscus. Nor is the loss of heart-power at all comparable to the deadly paralysis sometimes produced by chloroform. It comes on gradually, rapidly to be sure, but still by degrees, and not abruptly, and as before hinted at, is always proportional to the dose. For these reasons, I do not see how the phenomenon can be explained otherwise than above, and believe it fairly demonstrated that nitrite of amyl acts upon man precisely as upon the lower animals. A recent writer in the *London Practitioner* deems the fact that the nitrite relieves the paroxysms of angina pectoris sufficient to prove that it is a stimulant. The truth is, we have no positive knowledge of the real nature of the disease alluded to. How futile then to attempt to explain the physiological action of a medicine by its effect upon it. This attempting to study physiologically a not understood medicine by its influence upon a not understood pathological condition, is unfortunately not new in medical annals; to complete its absurdity is only needed the common practice of explaining also the disease by the influence of the medicine upon it. Surely, this reading the unknown by the unknown resembles the youthful gambols of a kitten in pursuit of its tail—a circle of useless labour.

The question now arises of what practical value is the nitrite of amyl? Its peculiar physiological power of checking oxidation and lowering temperature suggests its use in fevers, when it is desirable to lessen the rapidity of the tissue changes. Its action upon the nervous and circulatory systems would, however, very possibly, do more harm in a low fever than its other powers would do good. I have, however no clinical evidence to offer, and therefore the matter must be left as a simple suggestion. There is one disease in which theoretically it ought to be of great value, *i.e.*, tetanus. There is scarcely any doubt but that there exists in that affection a condition of exalted functional activity of the reflex motor centres, and of these centres the nitrite is a powerful depressant. Moreover, in many cases of tetanus, there is an enormous rise in the activity of oxidation and consequently of temperature of the body, so that the nitrite would meet a second indication. Clinical evidence also is not altogether wanting, and although not enough to warrant any conclusion, is sufficient to encourage further trials.

Two cases of recovery from tetanus are reported in the *Lancet* of the present year (vol. 1. p. 572), one of which was treated by nitrite of amyl alone, the other by it and chloral. I am under the impression that another successful case has been reported, but cannot refer to it.

There is one fearfully painful affection, namely, angina pectoris, in which a considerable amount of clinical evidence shows the nitrite of amyl to be of very great value. Quite a number of cases have been reported, in which the inhalation has been of very great service in affording rapid and permanent relief. Nor are these cases limited to true angina pectoris, in which there is no evident organic cardiac diseases; on the contrary, many of the patients have been sufferers from very well marked valvular disease. Among the cases reported the following may be cited, the reporter's name and journal being alone given: Branton, *London Lancet*, 1869, and *Medical Times and Gazette*, 1870; Lieshmann, *Glasgow Medical Journal*, August, 1869; Maddon, *Edinburgh Medical Journal*, 1870; Anstie, Thompson, *Medical Times and Gazette*, 1870; also, *Clinical Society's Transactions*, vol. viii.

I have had an opportunity of using the nitrite in one case of severe suffering connected with valvular disease, and the effect in relieving the heart pang after the failure of other remedies was astonishing. The following *resumé* of the case is offered:—

H. D., coloured female, *æt.* twenty-one, sick in Philadelphia Hospital with chronic pneumonia and heart symptoms believed to depend upon chronic mitral disease. There was slight increase of cardiac dulness, with a soft, but loud systolic murmur, loudest at the apex, but audible at the base, and very distinct between the shoulders.

*Feb.* 20.—Commenced to suffer with paroxysms of severe pain in the region of the heart, with suffocative feeling; chiefly complained of a gripping sensation, as if some one was holding and choking her in the cardiac region. She stated that she was in agony, and appeared to suffer violent pain. Various remedies were used without decided relief; I copy now from my note-book.

*March* 2.—Suffered from anginous attack last night; during a "spell" this morning was allowed to inhale nitrite of amyl very cautiously, with apparently marked relief and shortening

of paroxysm. 3 p.m. Found by Dr. McCoy, resident physician, suffering from a severe spell. He reports: "Her pulse was 34 in a quarter of a minute. Five gtt. of the nitrite were placed upon a handkerchief and held over her nostrils. In second quarter of a minute pulse rose to 40; third quarter, 39, and Dr. Bullard, of Brooklyn, who was present, said 'weaker.' In a minute she appeared easy, reclining on a pillow (during paroxysm she always sat up bent forward), and soon after she said her pain was gone."

*3d.*—Had a very severe spell, during which she was seen by Dr. Murray (resident physician), who reports: "Found her suffering great agony; gave by inhalation 5 gtt. of the nitrite of amyl; pulse 37 in the quarter of a minute preceding inhalation; same for the three-quarters after giving the medicine; she appeared easy in half a minute; could not answer questions as to how she was for a minute after; heart agony instantly stopped."

*6th.*—Had a paroxysm during my visit; pulse 110; five gtt. of the nitrite on a handkerchief held at a little distance from her nostrils; 1 minute, says she is somewhat relieved; pulse 110; 2 minutes, 5 gtt. more put on handkerchief and held close to nose; 3 minutes, says she is completely relieved.

*15th.*—Has had several spells since last entry, all of them at once controlled by the nitrite. They have been gradually occurring at longer intervals, and have now apparently ceased.

*20th.*—Had no more spells.

In regard to the method of administration, I am not aware that the nitrite has been given otherwise than by inhalation. Its totally insoluble and highly volatile nature renders it unfit for exhibition either in solution or mixture; but I do not see why it could not be given dropped upon a piece of sugar. In cases of tetanus it seems plausible that the remedy would be more efficient if given by the stomach in frequent small doses. When it is to be inhaled, five drops should be placed upon a handkerchief and held close to the nostrils, the pulse being closely watched and taken as a guide for the continuance or withdrawal of the drug. If necessary the dose should be repeated. When giving it by the stomach I do not think it would be safe to start with more than two drops until the effects of the medicine so administered have been more studied than at present. Nitrite of amyl is without doubt a powerful agent in its action on the economy, and yet my experience with it on animals would seem to show that, with proper care and a due understanding of its physiological action it is a safe remedy. By this is meant that it does not act unexpectedly and out of proportion to the dose. I have never seen indications of anything such as constantly happens in the use of chloroform upon dogs, sudden arrest of the heart's action, unexpected death, the mysterious production of symptoms apparently out of proportion to the amount given. On the other hand, I have frequently been astonished at the ease with which very serious symptoms have been shaken off, the animal reacting rapidly from a condition on the very border lines of death.

#### NOTICES TO CORRESPONDENTS.

MEDICAL DECLARATION RESPECTING ALCOHOL.—Dr. Brown. We have forwarded your name, to be appended to the above declaration, to the President of the Royal College of Physicians, who supplied us with the signatures published in our last, and who will doubtless add the name to any future list which may be issued.

Dr. L.—You are perfectly correct in your assumption.

**Deaths.**

DAVENPORT.—On the 20th inst., at the Grange, Chigwell row, Essex, Chas. Davenport, L.S.A., aged 67.  
 HECKFORD.—On the 14th inst., at Ramsgate, Nathaniel Heckford, M.D., M.R.C.S.E., founder of the East London Hospital for Children, Ratcliffe-cross, after a lingering illness, brought on by his efforts to help the poor, especially in the East-end of London.  
 MACKENZIE.—On the 13th inst., D. J. MacKenzie, M.D., House-Physician, City Fever Hospital, Edinburgh, aged 29.  
 NORFON.—On the 5th inst., J. E. Norton, M.D., of Grey Friars, Chester.  
 SPENCER.—On the 7th inst., at Brompton, J. Frowd Spencer, M.R.C.S.E., formerly of Fonthill Gifford, Wilts, aged 89.

STOCKWELL FEVER HOSPITAL.—The Managers of the Metropolitan Asylum District require the services of a RESIDENT MEDICAL SUPERINTENDENT for the above Hospital. The appointment will be made upon a probation of three months, and the salary is £400 per annum, with an unfurnished residence (detached from the Hospital building), and coals and gas. Applicants must possess a Medical and Surgical qualification as required by the Regulations of the Local Government Board, and produce satisfactory testimonials of their qualifications for the appointment. Forms, on which only applications will be received, may be obtained at the Offices, No. 37 Norfolk street, Strand, where the applications, accompanied by testimonials, are to be delivered by or before the 1st January, 1872.

By order,  
 W. F. JEBB, Clerk to the Board.  
 37 Norfolk street, W.C., 6th December, 1871.

COKESTOWN HOUSE, INSTITUTED FOR THE MEDICAL TREATMENT OF THE INSANE OF BOTH SEXES.

This highly respectable Mansion in no respect resembles, either internally or externally, what is usually known as an Asylum. The Demesne, Conservatories, Graperies, and Grounds are unusually extensive, and in good condition. There are Billiard Tables for both sexes, with indoor and outdoor amusements, including Vehicles. Cokestown House is within three miles of Carrick-on-Suir Station, with a like distance from Fiddow, both on the Waterford and Limerick Lines, and in connection with the G. S. & W. and Kilkenny Lines. For terms, and Form of Admission, apply to the Resident Physician. JOHN PEPPARD, M.D., &c.  
 Cokestown House, Piltown, co. Kilkenny.

THOMASTOWN UNION.

KNOCKTOPHER DISPENSARY DISTRICT.

MEDICAL OFFICER WANTED.—The COMMITTEE of the above District will, at their Meeting to be held at Stoneyford on THURSDAY, the 11th day of JANUARY, 1872, at the hour of Eleven o'clock, A.M., proceed to Elect a Medical Officer, having the proper qualifications (in the room of Dr. THOMAS BRADLEY, who resigned), at a Salary of Ninety-five Pounds per annum, exclusive of Registration and Vaccination Fees. Personal attendance of Candidates will be required. Applications, enclosing Testimonials and Qualifications, will be received up to Half-past Ten o'clock, A.M., on the abovesaid day, by JOHN BRADLEY, Hon. Sec. Inisnag, Stoneyford, December 12, 1871.

ESTABLISHED 1830.  
 NATIONAL LIFE ASSURANCE SOCIETY,  
 2 KING WILLIAM STREET, LONDON, E.C.,  
 FOR MUTUAL ASSURANCE.

This Society does NOT pay Commission for the introduction of business, and consequently does not employ any Agents to recommend it, but it offers great advantages to Assurers in the two points of most importance to them, viz. :— SAFETY, which is guaranteed by a Reserve Fund exceeding £600,000, being in the unusually large proportion of more than 90 PER CENT. of the whole of the premiums which have been received upon existing Policies; and LARGE BONUSES, the whole of the profits being applied in the gradual reduction and ultimate extinction of the Assurer's premium. Prospectuses forwarded post free on application to— CHARLES ANSELL, Junr., Actuary.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The next PROFESSIONAL EXAMINATION for the MEMBERSHIP will COMMENCE on THURSDAY, the 18th JANUARY, 1872. Candidates are required to give fourteen days' notice in writing to the Registrar of the College, with whom all Certificates and Testimonials required by the Bye-laws are to be left at the same time. Pall Mall East, 1371. H. A. PITMAN, M.D., Registrar.

ROYAL FREE HOSPITAL, GRAY'S INN ROAD.—There is a vacancy for a JUNIOR HOUSE-SURGEON at this Hospital. Candidates, who must be members of the Royal College of Surgeons, are requested to send in their testimonials to the Secretary on or before Wednesday, the 27th inst. The appointment will be made for six months only, but the holder will be eligible for re-election. Board and residence are provided in the hospital.

JAMES S. BLYTH,  
 Secretary.

NAAS UNION.

KILCULLEN DISPENSARY DISTRICT.

THE COMMITTEE of MANAGEMENT of the Kileullen Dispensary District will, at their Meeting to be held at the Dispensary, Kileullen, on Friday, January 5th, at 12 o'clock, proceed to the appointment of a Medical Officer for the District, at a Salary of One Hundred Pounds per annum, exclusive of Registration and Vaccination fees.

The gentlemen to be appointed must possess the professional qualifications, prescribed by the Poor-law Commissioners, and will have to reside in the town of Kileullen.

Applications from Candidates (who are required to be in attendance), accompanied by testimonials, diplomas, &c., will be received by me, up to the hour of 11:30 o'clock, on the above day. The Clerk of the Naas Union will supply any information required.

R. H. BORROWES, Major,  
 Hon. Secretary.

Gilltown, Newbridge.

PRIVATE RETREAT

FOR

THE UPPER AND MIDDLE CLASSES

OF BOTH SEXES, MENTALLY AFFLICTED,

TUE BROOK VILLA,

NEAR LIVERPOOL.

Further information may be obtained on application to Dr. H. OWEN. Vide page 1075, "Medical Directory," 1869.

COCKING'S PATENT  
 POROPLASTIC SHEETS FOR SPLINTS.

AS SUPPLIED TO THE ARMIES AND NAVIES OF ENGLAND, FRANCE, PRUSSIA, RUSSIA, AUSTRIA, AND ITALY.

"Consists of a felted substance, is plastic when heated, and rigid when cold, rapidly and easily cut to any shape, and manipulated. We have no hesitation in recommending it as the best and most convenient Splint. The country practitioner will find it a special boon. Mr. Cocking (of Penzance) deserves it: thanks of many, inasmuch as he supplies it to hospitals almost at cost price."—*Medical Press*, Sept. 27, 1871.

"By attending to the very simple directions for use, the most perfect splint yet known, may be made. We earnestly recommend it to army surgeons, believing that for field hospital purposes, it will supersede all others."—*British Medical Journal*, Sept. 23, 1871.

"Mr. Cocking (of Penzance), has laid the profession under much obligation by his sheets for splints, which have succeeded admirably, and will prove highly useful to the surgeon, particularly in the country."—*Lancet*, Sept. 16, 1871.

"To practitioners in the country and colonies, "Cocking's Splint" will be of the utmost service. It has been used with success by our leading surgeons, and has found to answer all that was required or expected."—*Medical Times*, Oct. 7, 1871.

"We believe it is destined to displace the old-fashioned splints, as by keeping a small stock of it, the surgeon is ready to put up any fracture to which he may be called. No country doctor should be without it."

"To Country and Colonial Practitioners, invaluable."—Extract from the report of the London Hospital, by Jonathan Hutchinson, Esq., Senior Surgeon, Sep. 29, 1871.

"A great boon to medical men in the country. In town and hospital practice invaluable. Its porosity is one of its greatest advantages."—Extract from report by John Croft, Esq., of St. Thomas's Hospital, Oct. 6, 1871.

"Without doubt the material will come into very extensive use, when its valuable qualities shall have become more generally known."—Extract from report by A. E. Durham, Esq., Oct. of Guy's Hospital, 7, 1871.

1 RATHMINES TERRACE, RATHMINES

AND

102 UPPER GEORGE'S STREET, KINGSTOWN.

**RICHARD ALLEN**, Sole Manufacturer of the "MAMMOTH" IRISH FRIEZE TRAVELLING COAT. Price £3 10 0 ready-made.

These Coats are exceedingly valuable to all who are occasionally exposed to rough weather, or who have frequent occasion to travel, while to Gentleman Farmers, and Professional Gentlemen, they are well-nigh indispensable.

Patterns and Forms for Self-measurement may be had on application from the Sole Manufacturer, RICHARD ALLEN, 28 Lower Sackville street, and 52 High street, Dublin; and 49 Patrick street, Cork.

**GLENFIELD STARCH.**

EXCLUSIVELY USED IN THE ROYAL LAUNDRY

And Her Majesty's Laundress says that it is

THE FINEST STARCH SHE EVER USED,

Awarded PRIZE MEDAL for its Superiority.

When you ask for

**GLENFIELD STARCH,**

See, that you get it, as inferior kinds are often substituted

WOTHERSPOON and CO., Glasgow and London.

Established 1848.

**PROFESSIONAL AGENCY AND MEDICAL TRANSFER OFFICE.**

50 LINCOLN'S INN FIELDS, W.C.

**J. BAXTER LANGLEY LL.D. M.R.C.S., F.L.S.,**

&c., (KING'S COLL.), and Author of VIA MEDICA.

Has always upon his books a large number of desirable investments and available Appointments for negotiation.

The business of the Professional Agency is based upon the general principle that no charge is made unless work has been done and services rendered.

No Commission charged to Purchasers.

Full information as to terms, &c., sent free on application.

Office hours, from 11 till 4; Saturdays excepted.

**PRACTICES AND PARTNERSHIPS NOW OPEN** for negotiation (in addition to those advertised in Dr. Langley's List, (which is sent post free on application)."

Y 375. PRACTICE and APPOINTMENTS suitable for a young professional man with limited means. Receipts £360, including transferable appointments £280. All expenses small, greater part of the premium may be paid by instalment.

Y 374. CHANNEL ISLANDS. In a charming locality where there is pleasant society; an unopposed practice realising upwards of £200 a year. Appointments £40; midwifery fees, £1 1s. to £5 5s. Cheap living and low rent.

Y 373. DEATH VACANCY. A suitable gentleman can be introduced to the practice of a surgeon suddenly deceased, within 100 miles of London; the actual income has been about £450 a year, including appointments yielding £140, the whole of which can be transferred; there is no opposition within four miles, and the investment is an unusually safe one; the house is rather small, but commodious with garden, stabling, &c. Patients of a good class. An efficient locum tenens is in charge, and the widow can give a very good introduction.

Y 372. In the suburbs of LONDON, a PRACTICE and open dispensary realising upwards of £400 a year, of which £200 is taken in cash; there is great scope for increase, and the whole connexion is believed to be transferable.

Y 370. COUNTRY PRACTICE with appointment. Receipts £600 a year; patients good middle class; the whole connexion can be transferred for a gentleman commencing private practice; this is an excellent investment, as moderate terms would be accepted.

Y 367. HYDROPATHIC ESTABLISHMENT conducted upon professional principles, for sale with partnership introduction if desired. The residence is large and commodious, in a fashionable watering place, and the baths are modern and in perfect order, the average income is £1,400 a year, of which at least £1,000 could be safely transferred to a suitable gentleman, whilst by slight addition to the building £2,000 a year could be secured. The establishment has been for many years in successful operation, and the highest references can be given. The occupation is well suited for a professional man desiring to retire from active labour, especially if his wife were willing to superintend the household management.

Y 366. NON-DISPENSING PRACTICE on the SOUTH COAST in a large town where there is a public hospital, &c. Receipts £600 a year, but capable of large increase as the present incumbent suffers from disabilities which would not interfere with his successor. Appointments yield £65 a year, there is very little midwifery. The house is situate in the professional quarter, is convenient and held at a moderate rent. Terms, a year and a half's purchase, part of which may be left on security.

Y 364 SURREY. Within 20 miles of LONDON. The nucleus of a practice capable of great development. The receipts during the last two years have been £470, population upwards of 5,000; very little opposition. Expenses very small.

**LOCUM TENENS WANTED.** A doubly qualified gentleman of experience and character may obtain constant employment on Dr. Langley's staff at £3 3s. a week and all expenses. Immediate personal application necessary.
